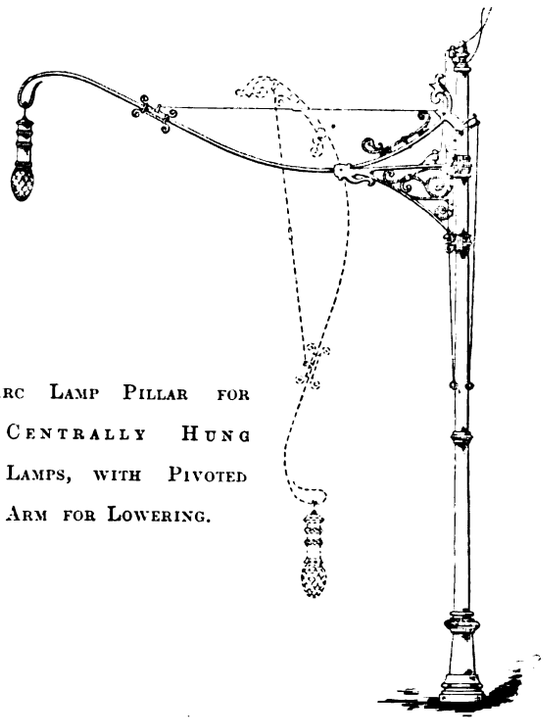
Mr. H. Dickinson (Chief Engineer, Leeds Corporation) was inclined to the opinion that in this country the rating of conductors was too low. No doubt in all supply undertakings there are cases where individual mains are overloaded, but personally he had found no trouble, except in reduction of pressure. He thought that a higher rating could be allowed with perfect safety. The thickness of the dielectric ought to be kept up; if it is thin and perishes, cracks occur and let in moisture, but if thick, although perished, the protection is much better. There are many old installations where the rubber has perished, but the insulation test remains good. They could not put customers to the expense of rewiring their installations, but agreed to connect them to the service, except in exceptionally bad cases. The precautions taken are to see that the fusing is particularly well attended to.

Mr. Steinthal in reply said it had been the general practice in Germany in the early days to use "Continental wiring," but now that higher pressures were being adopted, *papier-mâché* tubes were being used. Wood casing was very uncommon in Germany. He agreed with Dr. Pohl that the Germans knew what they were doing with regard to current density. The non-marking of switches with the nominal working current and pressure was principally the fault of the manufacturers, and it would be a desirable practice to enforce. Replying to the question respecting foreign cables, he said most German manufacturers were far too cute to send their thinner cables over here, but what they sent were made specially to pass our requirements. It would be much better in all respects if we were confined to one set of rules, and would be the means of getting rid of a great deal of inferior work.



Institution of Electrical Engineers.—The following is the result of the ballot for new members at the meeting on Thursday:—*Associate Members:* R. Blackmore, A. L. Boyle, K. M. Faye-Hansen, J. Hey, D. James, H. C. Ogilvie, B. Smith.

1,650-Mile Electric Railway.—It is stated that the St. Paul, Minneapolis, and Settle Electric Railway Co., recently incorporated with a capital of $50,000,000 to build an electric railway between Twin City and Puget Sound, will shortly commence laying the track for the first section. The line will be 1,650 miles in length, and it is anticipated that the first division to the Red River Valley will be completed in eighteen months. The route adopted will be 200 miles shorter from St. Paul to Settle than either the existing Northern Pacific or the Great Northern Railways. The line will be double track, and the third rail system is to be used throughout.

AN ARC LAMP PILLAR FOR CENTRAL LIGHTING

THE practice of lighting streets by centrally suspended arc lamps has, on the whole, been given more attention on the Continent than in this country, though this arrangement has been adopted in a few isolated cases in England—notably in the case of the experimental lighting of Cannon Street in the City of London. The most usual arrangement is to stretch cross-wires along the street, and in some cases arrangements of pulleys are adopted to lower the lamps for trimming.

A somewhat different arrangement, which has been adopted at Levallois-Perret, near Paris, is described in a recent number of *L'Electricien*, and is shown in the accompanying illustration. As will be seen, the lamp is mounted on a long bracket-arm

Arc Lamp Pillar for Centrally Hung Lamps, with Pivoted Arm for Lowering.

carried by a tubular pole, and pivoted so that the lamp can be lowered. The long, movable arm is pivoted at a point at the end of a short, fixed bracket, and is balanced by a weight suspended from a wire rope, and contained within the tubular pole. There is also a locking arrangement which can be released when the lamp is to be lowered by a rope terminating in a ring which is reached by a hook at the end of a pole. The other rope shown at the left-hand side of the post passes round a pulley, and raises the counterweight when pulled, allowing the arm and lamp to swing down into the position shown dotted in the illustration. This form of post has superseded a somewhat unsatisfactory arrangement of cross-wires and pulleys for drawing to the side and lowering, and has been so successful that about 400 are being put up.

Repairing Electric Light Street Boxes.—In the City of London Court on Friday, the French Asphalt Co., sued the City of London Electric Lighting Co., for £3 8s. for making good the footway round eight electric lighting street boxes in Fleet Street. The French Asphalt Co., it appears, has a contract with the City Corporation for repairing certain streets in the City of London, including Fleet Street. They recently discovered that the pavement around eight electric lighting boxes belonging to the City of London Electric Lighting Co., was in a sunken condition, and under their contract with the City Corporation effected the necessary repairs, and charged the account to the company. As the Electric Lighting Co. was not notified that the work was being done and no price was quoted them, they refused to meet the account. Judge Rentoul, K.C., after hearing evidence, held that as the defendants had not ordered the work they were not liable for the cost. There seemed to be many legal intricacies in the matter which the French Asphalt Co. could not deal with without advice. He suggested that they should take legal advice, and if they decided to go on, the Electric Lighting Co. must be awarded costs.

THE POULSEN WIRELESS TELEGRAPHY STATION AT LYNGBY

In a former article (see Electrical Engineering, Vol. II., p. 765), describing the Poulsen station at Knockroe, Tralee Bay, Ireland, which is to be used for transatlantic telegraphy, reference was made to the Copenhagen station, which had then been for some time in communication with a station near Newcastle. The former station is situated at Lyngby, not far from Copenhagen, and was originally a small experimental station equipped with a 3·5 kw. 240-volt dynamo and a mast only 120 ft. high. Last summer the station was considerably enlarged, and now contains a 10 kw. 500-volt dynamo driven by a petrol motor capable of developing 20 h.p. The two wooden masts, each 230 ft. high, are 300 ft. apart, and support a stranded copper cable, to which are attached twenty-three copper conductors. These are spread out on either side by means of insulated guide-ropes and brought together again below, forming a roof-shaped aerial. The corresponding electrical "counterpoise" consists of a wire network spread out over the surface of the ground.

The 10 kw. dynamo supplies an oscillation generator composed of a single arc-gap in hydrogen. The electrodes are, as usual, copper and carbon respectively, the copper electrode being water-cooled if more than 5 or 6 kw. is being supplied to the arc. A strong transverse field is provided. The working of the Poulsen transmitter was described in Electrical Engineering, Vol. I., p. 81. The energy generated in the oscillation circuit varies, according to the wave-length employed, from 2 to 5 kw. The receiver in use at this station is the usual Poulsen "ticker," with telephone or relay and Morse printer. The new apparatus for registering the Morse signals photographically is also in use at Lyngby. Messages are received and recorded by this apparatus from the station at Cullercoats, near Newcastle, some 600 miles distant. The latter station has a dynamo of only 4·6 kw. capacity. The messages can be received by telephone and recorded by the above apparatus simultaneously. The ss. *Hellig Olav* has been in communication with the station at Lyngby up to distances of 1,200 miles with a wave-length of 4,000 ft. It will also be remembered that messages were received at Steglitz, near Berlin, from this same ship, when some 2,000 miles distant in mid-Atlantic. It has been found possible to receive two sets of messages simultaneously by means of one aerial with wave-lengths differing in effective length by only 3·5 per cent. Skilled operators can receive separate messages with a difference in wave-length of only 1 per cent., and it is partly to this high selective property that the superiority of the continuous-wave system over the damped-wave spark system is due.

An important improvement in the transmitter has recently been made, in that the complicated apparatus for producing the hydrogen has been replaced by an arrangement by which one or two drops of alcohol are introduced into the arc chamber every second (for a generator producing about one kilowatt in the oscillating circuit). The Lyngby station is in communication with Berlin and St. Petersburg as well as with Newcastle, and experiments are being made in wireless telephony.

THE NATIONAL PHYSICAL LABORATORY

The General Board of the Laboratory met at Bushey House, Teddington, on Friday last, and at the invitation of Lord Rayleigh, chairman of the General Board, several visitors were also present, and a general inspection of the new buildings and appliances was made. The annual report commences with a reference to the death of Lord Kelvin, who was a member of the General Board and a frequent visitor to the Laboratory. The late Sir Benjamin Baker was also a member of the General Board. During the past year research work of electrical interest has been carried out in several departments of the Laboratory, and the following notes on this work are taken from the report.

In the Physics Department several researches on electric measurements have been carried out and the results published in various Papers before societies. The Paper on the Ampère balance, by Prof. Ayrton, Mr. Mather, and Mr. Smith, was read before the Royal Society in June last. Measurements of a very high order of accuracy were obtained, and in consequence the ampere is now probably much more exactly determined than either of the other fundamental electrical units. A further Paper by Mr. Smith, Mr. Mather, and Dr. Lowry deals with the silver voltameter. Voltameters of six different patterns were compared, with the result that provided the electrolyte is a solution of pure nitrate of silver, the mass of silver deposited per coulomb is found to be the same in all, and to amount to 1·11827 milligrammes. The value found by Lord Rayleigh in 1884 was 1·1179. A third Paper by Mr. Smith deals with the Weston cadmium cell. A large number of these cells have been constructed, different methods of preparing the mercurous sulphate being tried. If sufficient care be taken to avoid hydrolysis, these different methods lead to the same result. The E.M.F. of the cell at 17° C. expressed in terms of the ampere as realised by the Ayrton-Jones balance and the international ohm set up in the Laboratory is 1·01830 volts, while comparisons with cells set up in Berlin, Paris, and Washington show differences of only a few microvolts. Some work has been done on the Lorenz apparatus, which the Drapers' Company are to present in memory of the late Professor Viriamu Jones. Mr. Campbell's researches have chiefly been connected with the methods of measuring to a high order of accuracy small capacities and inductances. For this purpose a large standard of mutual inductance, the value of which can be calculated with great accuracy from its dimensions, has been set up. Methods of comparing self-inductances involving the use of a new form of vibration galvanometer and of a variable mutual inductance have been devised. This work has been carried on in preparation for some investigations into methods of measuring oscillation frequencies in wave telegraphy, which the Laboratory has been asked to carry out for the Post Office. Progress in the interesting experiments on the dielectric resistance of insulating materials under high stresses has been stopped by the failure of the 100,000-volt transformer which was built for the Engineering Standards Committee. A number of experiments have been made with a view to setting up an apparatus to give an approximate indication of the loudness of noise. A sensitive indicating arrangement was obtained by connecting a microphone transmitter and battery to the primary of a transformer of very high ratio (*e.g.*, 1 : 500)—an ordinary spark coil being suitable; the secondary circuit was connected to a low-reading electrostatic voltmeter. The experiments brought out clearly the fact that an ordinary "solid-back" transmitter has several strongly marked resonance frequencies (*e.g.*, at about 500 and 1,000 ~ per second) lying quite within the range of ordinary speech.

The total number of instruments and apparatus tested has increased greatly, and this increase extends over practically all divisions of the work. A comparison of tests made during the years 1906 and 1907 shows that in the Physics Department, 254 electrical measurement tests were made in 1907 against 74 in 1906. In 1907, 897 tests included under the heading of Electrotechnics were made, against 696 in 1906. In the Photometry Department 400 tests were made in the year 1907, all of these being incandescent lamp tests; the corresponding number in 1906 was only 214, out of which 205 were incandescent lamps. Among the more interesting inquiries may be mentioned an examination into a large number of old and modern rails for the Great Northern Railway, and the investigation for the Board of Trade into the cause of failure of a thermal storage drum at Greenwich. In the Photometric Division, a large number of lamps have been tested for life in accordance with the specification of the Engineering Standards Committee. The Magnetic Observatory at Eskdalemuir is now practically complete, and a staff has been appointed. The sums paid during the year include £1,476 for the equipment of the new electricity building and £300 for the building and equipment of a transformer house.

During the year a Committee appointed by the Treasury has been sitting to inquire into the work now performed at the National Physical Laboratory, with special reference to the character of the tests undertaken. The report of the Committee has been communicated to the Royal Society by the Secretary of the Treasury, with the intimation that their Lordships accept the recommendations of the Committee, and they trust that the Royal Society will do the same. In reply, the

Digitized by Google

President and Council, at the request of the Executive Committee of the Laboratory, have expressed their readiness to use their best endeavours to carry the report into effect. In the future, with the exceptions specified in the report, tests on materials will only be carried out on the receipt of a request addressed to the director, on an official form, supplied by the Laboratory. The conditions under which such tests are undertaken will be printed on the form, together with a statement, to be signed by the applicant, that his application is made subject to these conditions.

The report includes a statement of the proposed work for the year 1908. In the Physics Department the standard condensers will be tested against the new mutual inductance standards, and the latter will be used as a basis for the measurement of self-inductance. The variable mutual inductance standards will be checked against them, and by their means the effect of variation in frequency upon self-inductance will be investigated. The experiments for the determination of high frequencies will be continued. A number of experiments have been already made on the behaviour of insulating materials (such as are used in telephone cables) at different frequencies, as regards their effective resistivity and permittivity (inductive capacity). These will be extended to higher frequencies. The high-frequency alternator will be completed, and a new wire interrupter set up. The marble variable inductance will be completed. The hysteresis research will be continued, and arrangements for determination of total iron losses improved. In the photometric section a new set of electric sub-standards, running at a higher efficiency than those now in use, will be established. These are needed for work with new metallic filament glow lamps. The existing lamps run at about four watts per candle. It is proposed to make two new sets, one to run at about 2·8 and the other at 2 watts per candle. The question of stepping from the redder to the whiter light will need careful investigation. By employing intermediate steps of small colour gradation, it is hoped to produce a set of standards which will accurately represent the equivalent of the candle in a whiter light. It is also intended to construct an arrangement for the measurement of mean candle-power by the rotation of mirrors, instead of by spinning the lamp itself—so that lamps may be tested whose filaments are too delicate to allow of rotation. Special attention is being paid to the installation of a very complete equipment for dealing with large quantities of life tests on lamps under the Engineering Standards Committee specification. The sub-Committee of the Engineering Standards Committee which is dealing with fuses desires experiments carried out on various types of fuses, with the object of determining the safe distance between contacts to be prescribed. It is proposed to test both open and enclosed types, and also to determine the fusing currents of various kinds of wire. Several individuals and institutions unconnected with the Laboratory are also co-operating in the work. It is probable that investigations on the larger fuses will be made by the Laboratory staff at some central station, where the larger capacity of the plant will admit of short circuiting tests being carried out without danger to the machinery and apparatus.

With regard to determination of oscillation frequencies in wave telegraphy, the problem of calibrating the various wave meters used for measuring high frequencies (*e.g.*, up to several million ~ per second) has been taken up at the instance of the Post Office authorities. A standard wave meter is being arranged, consisting of a highly accurate variable air-condenser and a well-stranded coil of small self-inductance. For the measurement of such small inductances the variable mutual inductance is employed, and in this way small self-inductances from one microhenry upwards are measured with ease and accuracy. As the indicating instrument for the wave meter a Duddell thermo-galvanometer has been purchased. For the absolute determination of frequencies by photographing the spark, a rotating mirror has been constructed which can be driven at 100 to 150 revolutions per second. A Poulsen arc lamp, a large air-condenser, and tuning coils are under construction.

The Post Office, the National Telephone Co., and other authorities have been consulted, with a view to evolving, if possible, a standard test for dry cells. This may involve the testing of a large number of cells over a long period of time.

The report also contains a list of papers published by the Laboratory or communicated by members of the staff to scientific societies, and an appendix to the report gives a full description of the new electrotechnical buildings and equipment.

The Aldwych-Embankment Subway.—It is stated that the through tramway service between the north and south of London *viâ* the Aldwych subway and the Embankment will be opened on April 10th. A description of the subway and its equipment was given in Electrical Engineering, March 5th, p. 343. Since that time the work of laying the track has been rapidly pushed forward, and the whole of the special work for the junction with the Embankment lines has been put in position during the last few days.

ACCUMULATOR RAILWAY CARS IN GERMANY

Some particulars of the accumulator motor coaches put into service just a year ago by the Prussian State Railways in the neighbourhood of Mainz, were published in Electrical Engineering, Vol. II., p. 206. The following further particulars of the electrical equipment, charging arrangements, and working results for the first year are taken from an article by K. Fürst in a recent issue of the *Elektrotechnische Zeitschrift*. The cells, of which there are 180 in each car, weigh 111 lb. each; and as they are rated at 200 ampere-hours under normal running conditions, this gives 3·6 watt-hours per lb. weight of cell. The estimated life of the positive plates is some 70,000 car-miles, and of the negative plates some 37,000 car-miles. A record has been kept for some cells, and it is found that after a total run of 10,000 car-miles, the capacity is considerably higher than that guaranteed, and the deposit is only 0·47 inch in depth. The average efficiency of the cells, obtained by taking the ratio of the utilised energy to the energy supplied to all coaches over a month's working, worked out at 76 per cent. The firm which supplied the cells (Akkumulatoren Fabrik-A.G., Berlin) has contracted to keep all the batteries in good condition, and to replace all parts damaged through use under normal conditions, for a charge of 1·55d. per car-mile for a period of five years.

The charging station at Mainz contains one 100 h.p. 160 r.p.m. Diesel oil engine, direct-coupled to a 75 kw. direct-current generator. Normally one car is charged at a time, taking from 110 to 120 amperes, but two cars could be charged at the same time if necessary. There is also a three-phase asynchronous motor, which can be connected to the town three-phase mains, and which is direct-coupled to a 50 kw. direct-current generator. This set was used before the Diesel motor set was installed, and is now only employed as a reserve. The total cost of this charging plant was £2,965.

The cars run on three lengths of track—from Mainz to Gau-Algesheim (13·2 miles), four return journeys per day; from Mainz to Oppenheim (12·7 miles), four return journeys per day; and from Mainz to Rüsselsheim (7·6 miles), six return journeys per day.

The cars are recharged after each journey from Mainz and back in the first two cases, but two journeys to Rüsselsheim are made on one charge. The times taken to recharge at a rate of 110 to 120 amperes are as follows:—After a journey to Oppenheim and back (25·4 miles), about 40 minutes; after one journey to Rüsselsheim and back (13·2 miles), about 25 minutes. There are five cars in all—three working, one in reserve, and one under repair. The average energy consumption is some 30 watt-hours per ton-mile. The average speed about 20 miles per hour, and the average distance between stops 2·5 miles.

The following are the approximate working costs in pence per car-mile:—

Cost of energy supplied to cells	1·36d.
Lubrication, cleaning, and heating	0·27d.
Wages of driver	1·16d.
Wages of conductor	0·89d.
Depreciation of cells (including renewals) ...	1·55d.
Depreciation of motors and equipment ...	0·085d.
Depreciation of car-bodies and bogies	0·36d.
Total	5·675d.

It is proposed to run the cars without conductors, which would reduce the above figure by 16 per cent. In order to obtain the total working costs, the amount of 1·85d. per car-mile must be included for interest on the capital cost of the charging installation and rolling-stock. This makes the total working cost 7·525d. per car-mile. The figure of 1·85d. per car-mile for interest on capital cost is based on the assumption that each car travels 21,000 miles during the year. The figure of 1·36d. per car-mile for the cost of energy is based on a generating cost of 0·875d. per kw.-hour, which is the total cost of generating with the Diesel motor set. If the motor-generator set is used, the cost is about three times as great, as besides the extra losses in the transformation, the charge of the town supply is 1·8d. per kw.-hour. The working results have been so satisfactory that the Prussian State Railways have ordered 57 more of these accumulator cars, which are to be delivered during this year.

Monte Video Tramways.—It is stated that the equipment of the 80 miles of line owned by the United Electric Tramways Co. of Monte Video will be completed by the end of June. According to the *Stock Exchange Gazette*, the lines, when fully electrified, will represent a capitalisation of £20,000 per mile, a figure below that of any other leading tramway company in South America.

NEW HIGH-TENSION SWITCHBOARD AT WOLVERHAMPTON

As briefly mentioned in the article in our last issue describing the extensions to the generating plant in the Corporation Electricity Works at Wolverhampton, one of the features of the additions to the equipment of the station is the new three-phase high-tension switchboard which has been installed by the Electric Construction Co. The position of the switchgear, alongside the older continuous-current board towards the end of the station, where the new generating sets are placed, although not actually in the new portion of the building, was indicated in the large plan of the station given on page 436 of the article referred to, and a photograph showing the general appearance of the operating panels is here reproduced in Fig. 1.

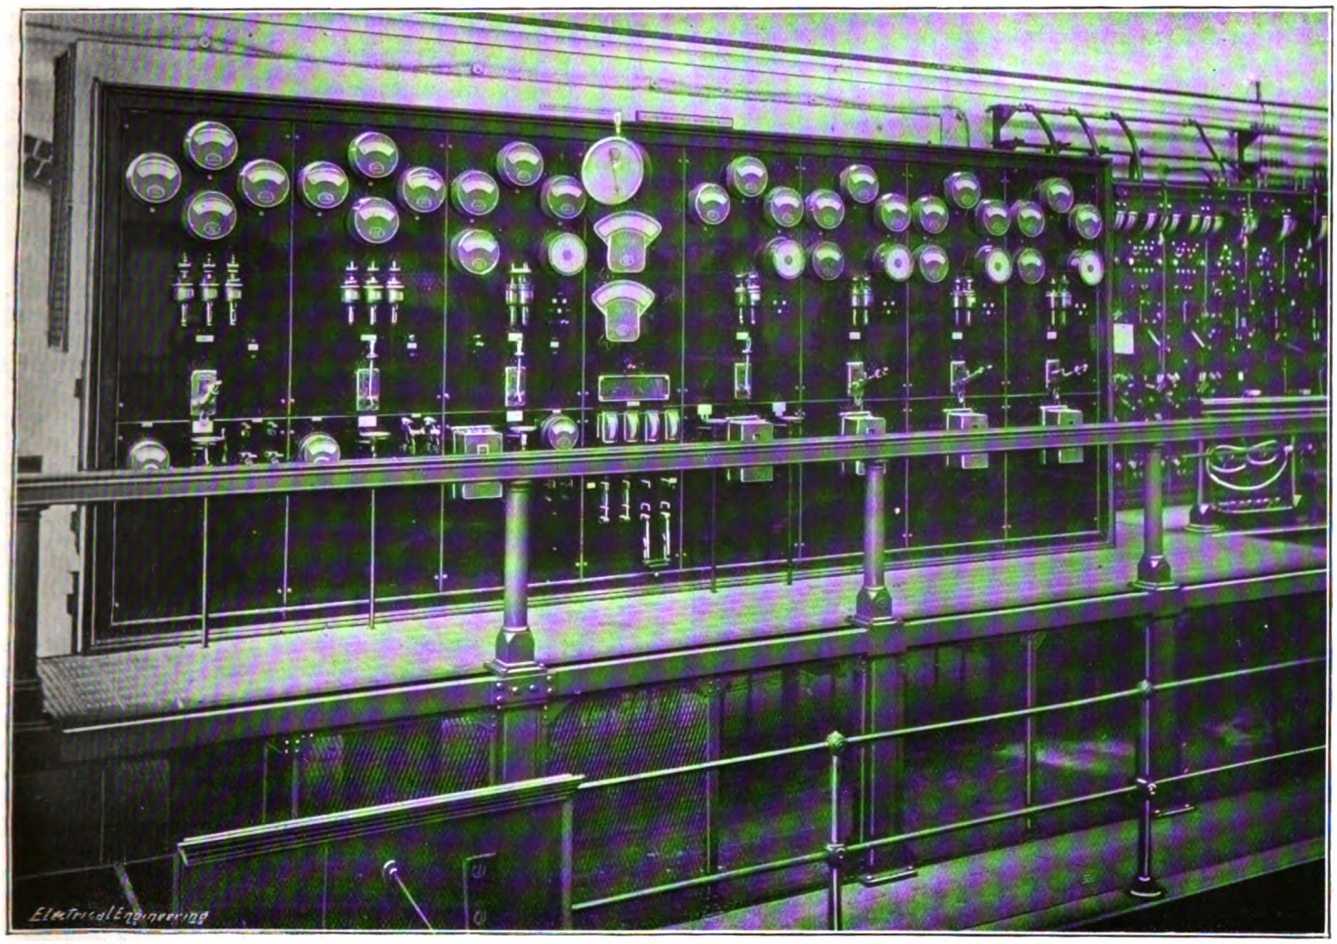

Fig. 1.—Front View of new 6,000-volt Switchboard.

As will be seen, the board is placed on a low gallery with a glass floor, which forms a continuation of the gallery of the continuous-current board. All high-tension apparatus is contained in cells separated by a passage-way behind the board itself. The actual board consists of eight slate panels, comprising two generator panels, a panel devoted to each of the converter sets, three power feeder panels, and a panel upon which are mounted the synchronising instruments, and also some of the switches and instruments belonging to the exciter circuits.

In general, it may be said that the front panels carry all instruments, operating levers, and low-tension switches, while all high-tension apparatus and connections are mounted in reinforced concrete cells placed against the wall behind the board. The cells are closed with expanded metal lock-up doors, and are shown in the side view given in Fig. 2.

The instruments for the high-tension circuits, which are mounted on the operating board, are all worked from the secondary side of transformers fixed in the cells in the usual way, and the whole arrangement is such that in the ordinary working of the board the high-tension connections and apparatus are inaccessible to unauthorised persons. The cells are in two tiers, and each forms an independent unit. The doors are carried on hinges, but so arranged that they can be lifted off when required. The expanded metal is of $1\frac{1}{2}$ in. $\times \frac{1}{8}$ in. $\times \frac{1}{8}$ in. mesh No. 24 metal.

The framing of the operating board consists of 6 in $\times$ 3 in. channel base, and 3 in. $\times$ 3 in. vertical H section joists. A 3 in. $\times$ 3 in. angle is provided for carrying the platform in front of the switchboard, also horizontal angles at the back for carrying the portable platform and the rails for removing the oil switches.

The panels themselves are of paraffined slate $1\frac{1}{2}$ in. thick, of the same height as the original continuous-current board, and a polished teak moulding has been provided top and bottom to match the older panels.

Before describing the equipment of the various panels and cells in detail, attention may be directed to the diagram of connections given in Fig. 3. It will be seen that the 'bus-bars are arranged in a kind of ring, and that isolating switches are provided so that they can be sectionalised to a considerable extent. The 'bus-bars themselves consist of 0·5 sq. in. bare copper throughout the main and return portions. Each phase of the

Digitized by Google

'bus-bars is totally enclosed in a separate concrete cell, and the arrangement is such that extensions could readily be made. The isolating switches are, of course, contained in the cells in positions shown in Fig. 4. They are so arranged that the three poles are operated together, as this is found to be more convenient in the case of the 'bus-bars than single-pole switches. It will be noted that the switches in the 'bus-bar circuits isolate the circuits in addition to fulfilling the function of dividing the bars. The isolating switches in the 'bus-bars are equivalent to the carrying capacity of 0.5 sq. in. wrought copper, while those at the cable ends of the feeders are equal to carrying 200 amperes. All these switches are worked from the passage-way behind the board by keys without opening the doors of the cells. As they are all of the same design, only one key is provided for all of them.

The two generator panels for the new 1,000 kw.

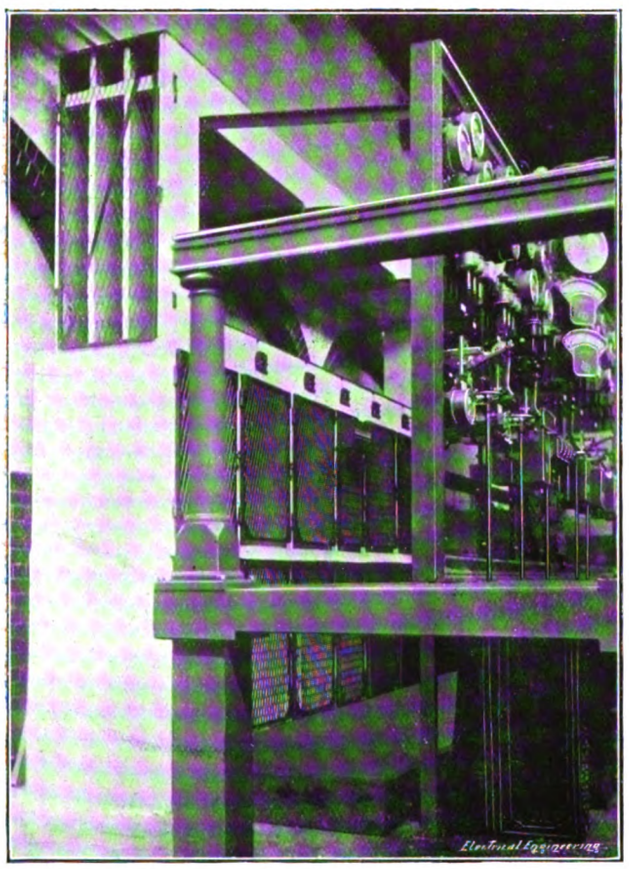

Fig. 2.—Side View of Switchboard, showing E.H.T. Cells.

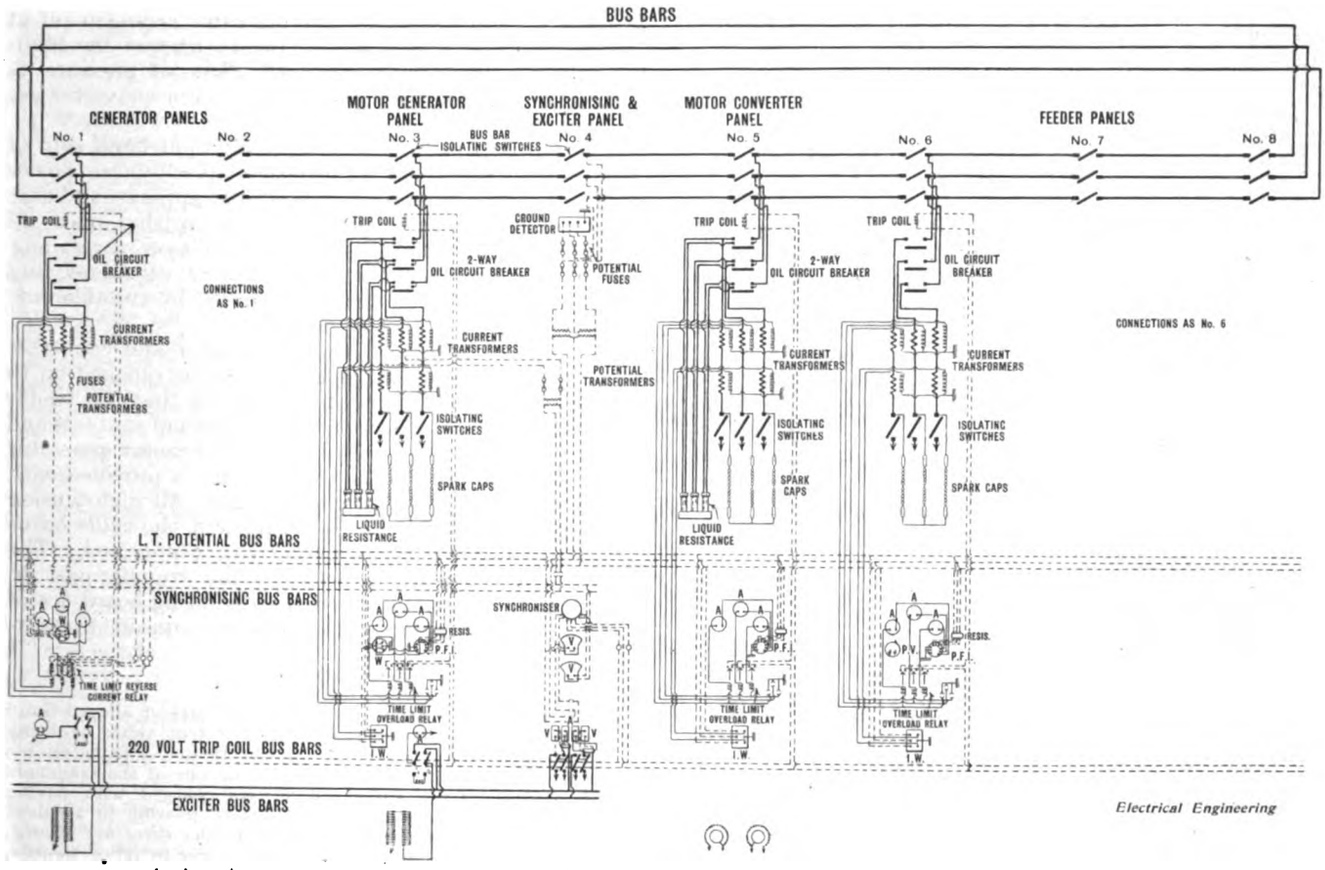
6,600-volt three-phase alternators are placed at the left-hand side of the board. The levers for operating the main oil switches are arranged in the centres of the panels, and actuate the high-tension gear in the cells behind through a system of rods passing under the floor of the passage-way. The oil switches themselves are of the standard E.C.C. 6,600-volt type, and have all been tested and found capable of breaking 2,000 kw. at 10,000 volts. They are fitted with tripping coils wound for continuous current. The arrangement of the operating lever is such that the switch cannot be held closed under an overload. Should the switch trip automatically the handle on the operating board immediately moves to the "off" position, thereby indicating that the circuit has opened. Each phase has a double break in a separate oil tank. A set of rails for supporting the circuit-breakers when drawn out of the cell is provided. The switches are shown in position in Figs. 4 and 5.



The reverse current time-limit relays are of the British Thomson-Houston Co.'s manufacture, and are mounted on the front of the panels above the switch levers. Overload relays are not used on the generator circuits. As will be seen from Fig. 1, all the main indicating instruments are mounted at the top part of the panels. Those on the generator panels comprise three ammeters and an indicating wattmeter for unbalanced loads. Separate machine voltmeters are not provided, but the high-tension cells corresponding to each machine contain potential transformers, which can be plugged on to the voltmeter on the synchronising panel mentioned hereafter. All the instruments on the board are of Messrs. Everett, Edgcumbe & Co.'s manufacture. The ammeter and wattmeter are of the round pattern, with 8-in. dials. All have cast-iron cases enamelled black, with nickelled facings. As pointed out already, the ammeters are worked by current transformers. These are of E.C.C. standard open type, and are of course placed in the high-tension cells. The potential transformers in the generator circuits are of the single-phase type, and are contained in cast-iron cases filled with suitable oil. The current for the potential circuit of the machine wattmeter is not obtained from these transformers, but is derived from a two-phase transformer in the synchronising cell, which also furnishes all current to the potential circuits of all indicating wattmeters, integrating wattmeters, power-factor indicators, and one side of the synchroniser. The potential transformers are protected by fuses of the glass-tube dust type, held in clip contacts, and a set of ebonite tongs has been provided so that these can be replaced when alive.

The lower part of each generator panel is devoted to the excitation circuits. A pair of 80-volt exciting 'bus-bars run along all the generator panels. These are mounted on porcelain insulators on the uprights of the operating board framework, and are fixed below the platform level. The exciter gear on each generator panel comprises a double-pole field-breaking switch with non-inductive resistance and a round pattern ammeter with a 6-in. dial.

Between the ammeter and field-breaking switch is the small hand-wheel and vertical spindle by which the field-regulating rheostats are worked. The resistances themselves with their multiple-contact switches are placed under the gallery floor.

The next panel, which may be considered to all intents and purposes as a feeder panel, controls the circuits leading to the 500 kw. synchronous motor-generator. The arrangement is generally similar to the generator panels, except for certain additional apparatus. Among the instruments on the upper part of the board a direct-reading power-factor indicator is provided, with an arrangement of plug sockets by which the power factor of any phase can be observed. The oil switch and reverse current relays are also similar, except that two sets of contacts are provided on the oil switch, which come into action successively as the switch is put on. The object of these is to enable the voltage to be put on to the windings of the incoming machine through a set of water resistances before it is applied direct to its terminals, in a similar manner to the arrangement sometimes used for feeder charging. Further protection to the high-tension windings of the motor-generator is provided by a multi-gap static discharger of the British Thomson-Houston Co.'s standard 7,500-volt type. The position of this apparatus in the high-tension cells is seen in Fig. 4. The only other apparatus on this panel which does not correspond exactly to that on the 1,000 kw. generator panels is an integrating watt-hour meter on the lower part of the panel, connected, of course, to the appropriate current and potential transformers. It should be remarked that the synchronous motor-generator is always started up from the continuous-current side by means of the switchgear placed close to the machine itself, so that provision has only to

be made on this board for paralleling the synchronous motor on the high-tension bars and regulating its excitation in order to control the power factor.

The fourth panel, practically in the centre of the board, contains on its upper half the instrument for synchronising the circuits of the three panels already referred to. These consist of a rotary Everett & Edgcumbe synchroniser, with synchronising lamp and two voltmeters all mounted on swivel brackets. These voltmeters are of the sector pattern, with scales 12 in. long. The two-phase potential transformer in the synchronising high-tension cell has already been alluded to.

Under these instruments is a wide rectangular glass window, through which the leakage indicator, fixed with the high-tension apparatus behind the passage-way, can be seen. This instrument is connected directly to the high-tension 'bus-bars, and consists of three voltmeters of the electrostatic type, which indicate the difference of potential between each bar and earth.

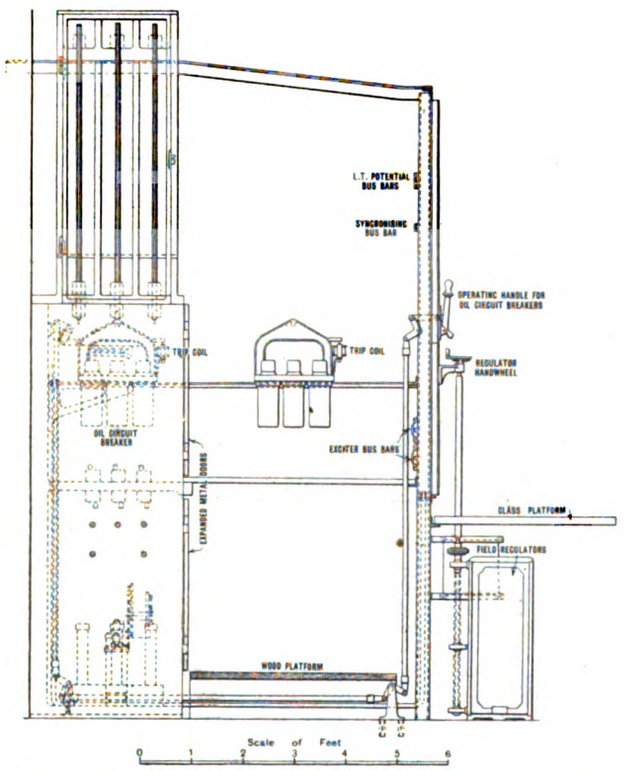

Fig. 5.—Section through Board, showing Oil Switch withdrawn for Inspection.

The somewhat novel arrangement of a window makes the instrument visible from the front of the board while still enabling all high-tension conductors to be kept away from it. The lower part of the panel is devoted to the exciters, and contains 6-in. edgewise ammeters and voltmeters for each set and a pair of quick-break double-pole knife switches for connecting either or both machines to the exciter bars. The exciter field regulators are operated by small hand-wheels and vertical spindles in a similar way to those of the alternators, but owing to lack of space on the exciter panel these have had to be placed in front of the next panel, although they really have no connection with the other apparatus thereon.

Immediately to the right of the synchronising and exciting panel is the panel for the 500 kw. motor-converter. As this is not a set which requires synchronising, the panel is practically equivalent to a feeder panel, and contains only a main switch with overload time-limit relay, three ammeters, a power-factor indicator, and an integrating watt-hour meter. The oil switch is fitted with extra contacts as in the case of the synchronous motor-generator, and the same arrangement of water resistances and spark gaps to protect the high-tension windings from abnormal rises of pressure is adopted. The starting gear of the motor-converter set is placed near the machine itself.

The remaining three panels on the right-hand side of the board are for the three special three-phase power feeders, and are equipped with similar apparatus to that in use on the rest of the board, comprising main oil switches with overload time-limit relays, three ammeters, a power-factor indicator, a pilot voltmeter, and an integrating watt-hour meter worked by suitable current and potential transformers.

As in the case of the motor generator and converter panels, the power-factor indicator can be plugged on to either phase. It should be pointed out that the feeder oil switches are not provided with additional contacts and water resistances, as in the case of the motor generator and converter circuits, but each feeder is provided with a B.T.-H. multi-gap static discharger. All high-tension connections between the 'bus-bars and the cable-boxes are of hard-drawn high-conductivity copper rod. The low-tension connections between the transformers in cells and the instruments on the operating board are of fire-proofed insulated cable, and are run in Simplex tubing.

American Patent Scandal.—A remarkable case of alleged fraud in connection with the United States Patent Office is being heard in America, in which Mr. J. A. Heany, a patentee, his agent, H. E. Everding, and N. W. Barton, one of the examiners of the United States Patent Office, are charged with having destroyed certain specifications and letters relating to a patent on metallic filament lamps. According to the *Electrical World*, Barton, by reason of his position, had access to office records, and was enabled, at a very recent date, to substitute for papers filed more than two years previously, certain other papers, and give them the same date as if they had been filed originally. The invention described in the substitute papers is thought to be very valuable, and a great advantage would attend it if a date of invention sufficiently early to antedate the prior inventions of others could be secured. To be successful in this plan it was necessary to destroy original records of the office, and file substitutes therefor, and by changing the dates of receiving stamps make it appear that such substitute papers were, in fact, actually filed upon the fictitious dates stamped on the papers.

A Rat Causes Interruption to Supply.—A serious interruption to the electricity supply of Charlottenburg, owing to a rat having caused a short-circuit, took place on Tuesday, February 18th. The engineer-in-chief has supplied us with the following particulars :—A rat crept in between the contacts of a high-tension oil switch and caused a short-circuit. As the contacts which the rat connected were on the bus-bar side of the switch, the maximum relay operated, and the main generator was switched off from the bus-bars. Had the rat shorted the opposite contacts, the single feeder only would have been disconnected by the action of the automatic oil switch. The contacts of the oil switch were badly burnt, but as soon as the fault was localised, the supply was resumed. A similar case occurred in Charlottenburg some time ago, when a rat, having entered a transformer kiosk, came in contact with both the high-tension mains and earth. The station instruments indicated a heavy earth for a short time, but there was no interruption to the supply.

Electric Lighting in Bulawayo.—Before the Judicial Committee of the Privy Council on Wednesday last, the case of the Municipality of Bulawayo *v.* The Bulawayo Waterworks Co., Ltd., came up on an appeal from a judgment of the Supreme Court of the Cape of Good Hope, of November 5th, 1906. The arguments were heard last month, before a Board composed of the Earl of Halsbury, Lord Macnaughten, Lord Atkinson, and Sir Arthur Wilson, when judgment was reserved. Lord Macnaughten, in delivering judgment on Wednesday, said that according to the original agreement, the Municipality should pay the Company for the public lighting of the town "at such rate as will yield to the company a return equal to 10 per cent. over the actual cost of generating the light." Disputes had arisen as to the charge made, and the point to be decided was, what was the meaning of the expression "the actual cost of generating the light." Their lordships agreed that the term "generating the current" was intended to include not only the generation, but also the transmission of the current, and that the "actual cost" included depreciation and insurance. Insurance was practically a necessity, and expenditure on insurance might be regarded as part of the actual cost, just as much as rent, rates, and taxes. Their lordships accordingly dismissed the appeal, the appellants paying the costs.

PETROL-ELECTRIC SYSTEMS FOR HEAVY VEHICLES

A PAPER was read by Mr. P. Frost Smith (Chief Engineer to Messrs. T. Tilling's Motor Department) and Mr. W. A. Stevens (Messrs. W. A. Stevens, Ltd., Maidstone) before a meeting of the Society of Road Traction Engineers last Monday on the development of petrol-electric systems and their application to heavy road vehicles, in which they considered the possibilities opened up by the introduction of electric transmission gear for motor omnibuses. After referring to the "appalling" financial losses of certain of the London motor omnibus undertakings, they gave it as their opinion, in the light of very considerable experience with the accepted type of gear-driven motor omnibuses, that it was "obviously necessary that an entirely different type of vehicle to those now most generally used must be introduced." The causes of this high expenditure were analysed, and the following figures were given representing the actual experience of the company with which one of the authors is connected.

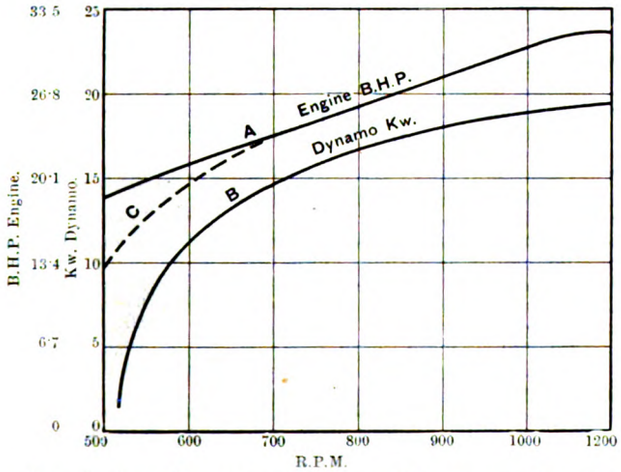
WORKING COSTS PER GEAR-DRIVEN PETROL OMNIBUSES.

	Pence per car mile.
Day running	0·265
Night running	0·750
Maintenance	2·443
Lubricants	0·241
Grease	0·080
Paraffin	0·040
Vehicle lighting	0·105
Body upkeep	0·250
Drivers	1·308
Tyres	1·750
Conductors	0·945
Petrol	1·325
Traffic expenses	0·255
Depreciation, insurance, rents, rates, taxes, water, gas, garage lighting, supervision, and establishment charges	2·189
Total	11·937

These figures, which were averages for three years, they said, showed the hopelessness of going on as they were now doing.

It was the object of the Paper to consider the saving in expense which might be obtained if the adoption of a "petrol-electric" vehicle were adopted in which an internal-combustion motor, direct-coupled to an electric generator, supplies electrical energy to electric motors, directly, or indirectly, connected to the road wheels, by which means the clutch, gear-box, and differential gear are dispensed with.

The work of earlier designers in this direction was briefly referred to, the authors proceeded to describe the design for



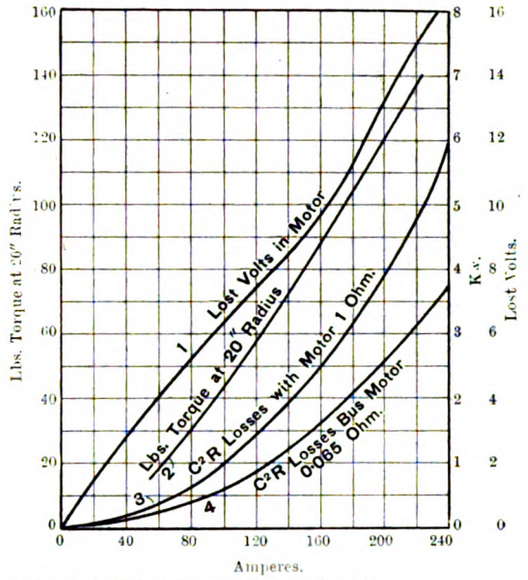


FIG. 1.—CHARACTERISTIC CURVES OF ENGINE AND DYNAMO.

which they were themselves partly responsible. This vehicle, the "Hallford" petrol-electric omnibus, which is electrically equipped on what is known as the S.B. and S. system, was described in considerable detail in ELECTRICAL ENGINEERING, January 16th, page 83. It will be remembered that it falls under the class of petrol-electric systems, in which the transmission is at all times electrical and does not employ batteries. A 30 h.p. four-cylinder engine drives a shunt-wound interpolar dynamo, which supplies current to two series-wound motors, one of which drives each back wheel through a specially-designed worm-gear. The use of a live back axle and a differential gear are thus entirely avoided. Provision is made for connecting the motor in series or parallel, but it is only in exceptional cases that the series notch is required. The control of the speed of the vehicle is effected almost entirely on the accelerator pedal and the field switch, and under ordinary conditions the main circuit is never broken, even at

4. C^2R Losses in Bus Motor 0·065 Ohm Res. at Varying Current Densities.

FIG. 2.

stopping. Before starting, unless the gradient is very steep, the controller lever is put into the parallel notch with the engine running slowly, and the generator field reduced. In order to start, the brakes are released, and the engine is accelerated by opening the throttle with the pedal, so that the voltage of the dynamo rises, the field switch is gradually moved over to raise the voltages as the vehicle gains speed. The running speed is then controlled by the throttle pedal, and to stop the throttle pedal is released, the dynamo field weakened, and the brake applied.

The actual omnibus has now run some 6,000 miles in ordinary service, and, as far as can be ascertained at present, seems to justify the hopes of its designers.

In discussing the conditions under which the petrol-electric drive will produce the greatest efficiency, the authors point out that if the petrol engine had the characteristics of the steam engine without its disadvantages, giving a heavy torque at slow speeds and a smaller torque at high speeds, or if a highly-efficient universal gear of low first cost, and low cost of upkeep could be produced, the petrol-electric system would have no claim to existence, but in the absence of these two conditions the ideal omnibus has still to be evolved, and they claim that the continuous-current petrol-electric system, with a suitable gear as the final transmission, from the electric motors to the road wheels, is the nearest approach to the ideal at present attained. In Fig. 1. the characteristic of the Hallford petrol engine is compared with the characteristic of the interpolar dynamo which it drives by means of a flexible coupling. The curve (A) represents the engine power read on the vertical divisions (or ordinates) as b.h.p. and the curve (B) the output of the dynamo in kilowatts, read directly on the vertical scale, the distance between the two curves as compared with the total engine power at any speed above 650 shows the efficiency of the conversion. To this end the scale of the engine b.h.p. is brought to odd vertical values, having the same ratio to the parallel values as the theoretical electrical horse-power has to the kilowatts. A dotted line (C) on engine characteristic indicates that the engine must be throttled down below the speed of 500 to allow the dynamo to lose its excitation, thereby

Digitized by Google

obviating the necessity of breaking the main switch in stopping the vehicle in traffic. It is not possible to show the characteristic of the dynamo under all conditions of demand for current at varying voltages; the curve, however, shows the average efficiency under ordinary running conditions. Speaking generally, the electrical transmission should be so designed that by its characteristics the lack of flexibility of the petrol engine is so corrected that the necessity for a clutch, the gear-box, and differential gear are obviated. The construction of the dynamo has a very essential bearing upon the successful development of the system. It must run absolutely sparklessly under all conditions of load. Its characteristic must be such that it will generate, approximately, constant watts, the volts, and amperes, varying in inverse ratio, according to the requirements of the series-wound motors, which, as will be seen later, demand current in almost direct ratio to the torque demanded by them by the road conditions. As the power of the petrol engine is limited, the volts must necessarily fall to keep the load on the engine constant. To this end the dynamo is designed with a falling characteristic similar to that of a shunt-wound generator, and by the employment of commutating poles, the sparking that would otherwise be present when working on a weak field with a heavy current is avoided.

As the conditions of efficiency in continuous-current petrol-electric systems are entirely different to those obtaining in tramway practice, owing to the total energy available for the electric motors being limited by the power of the petrol engine to produce that energy, and the obvious necessity under these conditions of the voltage falling in direct [illegible] the amperes demanded, as contrasted with the constant voltage supply of the tramway system, a consideration of the curves shown in the figure may be of interest, as they have a most important bearing on the efficiency, hill-climbing powers, and gear ratio for special conditions of work. The curves are taken from the motors of our petrol-electric omnibus.

Referring to Fig. 2, in which the ordinates represent lbs. torque at a radius of 20 in. (the radius of the ordinary omnibus wheel), the abscissæ represent amperes, and the curve marked (2) the torque values at varying current densities. These torque values are, practically, constant throughout the whole of the variation of speeds of the series-wound motor; the torque with a given current at two revolutions per minute being the same as at 1,000 revolutions per minute, the speed variation at a given torque being only affected by the voltage of supply. Considerably greater torque per ampere could be attained in a motor with a very small air gap, but such a motor would not be so efficient, at average loads, as the motor with a normal air gap. The vertical divisions on the outer right-hand side correspond with the curve (1), and are divided into volts. This curve represents the lost volts in the authors' type of motor, due to the fall of potential, caused by the current shown in the horizontal divisions. The vertical divisions on the inner right-hand side correspond with the curve (4), which represents lost kilowatts at various current densities, irrespective of the speed of the motor armature. The total internal resistance of each motor, including fields, brushes, and armature is 0·065 ohm. It will be seen that the above curve rapidly increases in value, being proportional to the square of the current density, and its importance will be clearly shown on consideration of the efficiencies obtained with a highly-geared vehicle with small engine power.

In the authors' experience the best gear ratio for electric motors, of the dimensions employed, is from 12 : 1 to 16 : 1; the former for town work, and the latter for mail van and country work generally, owing to its high efficiency on hills. With the 16 : 1 gear ratio, the efficiency of transmission in a petrol-electric vehicle, weighing, loaded, 7 tons on a hill of 1 in 12, including all electrical losses, and allowing 10 per cent. for gear losses, will work out at 70 per cent. from the engine to the road wheels. The efficiency of a 12 : 1 gear ratio under these conditions is 67 per cent. On ordinary "give-and-take" roads, the total efficiency from the engine to road-wheels averages over 70 per cent. The curve (3) demonstrates the C^2R losses in the armature, brushes, and fields of a smaller motor, which has a total resistance of 0·1 ohm, showing that with a current of 200 amperes, and a torque at 20-in. radius of 117 lb., a loss of 4 kw. in the machine would have to be made up before any external work could be done. This illustration is given to demonstrate the great loss of efficiency in a vehicle driven by small electric motors having a small gear ratio to the road wheels.

In the matter of durability of electrical equipment, the petrol-electric omnibus possesses the important advantage over the tramcar, in that the total electrical load on the dynamo and motors is limited by the power of the engine, and, as the dynamo and motors are, from considerations of electrical efficiency, made sufficiently large to stand 300 per cent. overload for a considerable time, to "burn out" through an overload is impossible. On a tramway system, on the other hand, this danger is ever present, the motors being at the mercy of the motorman with the full power of the generating station behind him. It is an easy matter in this case for a careless driver to switch on the full voltage of the line to his motors with both armatures and fields in parallel, when the car is starting or ascending a gradient, with the inevitable result of a "burn-out."

The Paper concludes with a few brief comparisons between gear-driven systems and the system therein described. This vehicle has only been in actual work and on a regular London service for eight weeks—covering 6,000 miles—yet in comparison with the recent much-talked-of R.A.C. trials, it shows up very well. The R.A.C. trials occupied 22 days, and the miles done daily were 40, chiefly on good "give-and-take" roads and where very few stoppages were required. It is not hills and bad roads that tell on motor-buses, so much as the continual stopping and starting of the vehicle, the heavy application of the brakes in the former circumstance, and wrong application of the clutch in the latter case. The vehicle cannot be started from a stationary position with a jerk, it simply glides away with a gentle, steady movement; this fact alone has a great bearing on the question of abnormal wear and tear. The control, from a driving point of view, is as nearly "fool-proof" as possible. The field resistance of the dynamo requires a little manipulation on the part of the driver, but not more so than a spark advance and retard lever. It must be emphasised that for London routes the driver never need come out of his top, or parallel, position, and thus the main electric circuit never need be broken, except in such cases when the driver leaves his vehicle and places the controller lever in the neutral position. The night staff on a fleet of such vehicles can be very greatly reduced, and it is confidently estimated that only 0·5 to 0·75 man per vehicle would be required. The labour required would be engine adjusters, brakesmen, greasers, cleaners, and washers. Electrical labour has been clearly demonstrated to be unnecessary on nightshifts, as the ordinary cleaning of the commutators would be done at the most suitable point on the vehicle's route during the day, as the operation only takes a few minutes to do.

With regard to maintenance, the authors have the strongest hopes of effecting a most substantial saving from the results already obtained. An engine such as has been employed may be safely taken to cost no more than ¼d. per mile on the very low basis of 30,000 miles run per annum; this mileage is more likely to approach 40,000 miles than the figure given, and at the time of writing the Paper the engine has cost nothing.

On the same basis as the above, the frame is estimated to cost ¼d., and the back axle the same sum. This latter was stripped after the 6,000-mile run for examination, and there were no visible signs of wear. Gears, ball-bearings, and other wearing parts were perfect. The electrical equipment has shown that with a suitably-designed dynamo and motors, the maintenance cost would be extremely low, and certainly not more than ¼d. per mile, though probably this figure, low as it is, would eventually be considerably reduced. The following table shows a comparison between the working cost figures given earlier and relating to the gear-driven types now in vogue, and the system forming the subject of this Paper.

Comparison of Working Costs of Petrol-electric and Gear-driven Types.

	Gear-driven.	Petrol-electric.
	Pence.	Pence.
Depreciation, insurance, &c., &c. ...	2·186	1·805
Day and night running charges ...	1·015	0·538
Maintenance	2·445	1·000
Lubricating oil	0·241	0·060
Grease	0·080	0·020
Paraffin	0·040	0·020
Other items (same as now)	5·938	5·938
Total	11·937	9·181

In the above table the petrol consumption has been shown as the same as on gear-driven vehicles, but, as a matter of fact, the distance run per gallon has averaged ¾ mile more.

In conclusion the authors express the opinion that if the above figures can, as they think, be realised in practice, over a period of some years, the solution of the problem of operating a fleet of motor-omnibuses with commercial success has been achieved.

THE EFFECT OF ELECTRICITY UPON PLANTS

THE *Proceedings* of the Naturalists' Society contains an interesting Paper by Mr. J. H. PRIESTLEY, B.Sc., on the effect of electricity on plants. During the last two years several attempts have been made in various localities to apply electricity as a stimulus to plant growth, and experiments upon an unusually large scale have been carried out by Mr. J. E. Newman at Bitton, near Bristol, and at Gloucester, in 1905, and at Bevington Hall, near Evesham, during 1906. Mr. Newman has kept Mr. Priestley closely in touch with his work, and has permitted him to embody his results in this Paper.

The first part of the Paper is Historical. The Scotch physician, Mambray, in Edinburgh, and about the same time Jallabert, in Geneva, carried out experiments upon the subject, and the success which they met with apparently caused the Abbé Nollet* to take up the subject in 1749. His experiments consisted in suspending iron plates upon steel chains hanging from a dry silk cord. Upon these insulated metal plates he kept animals and plants, and the whole series of trays were charged from a somewhat cumbrous influence machine requiring the continuous efforts of three men to drive; he found that maize and mustard thus electrified germinated in every case more rapidly than control plants. The Abbé Bertholon† (1783) greatly enhanced the practical interest of the subject by suggesting that atmospheric electricity was an important factor in the environment of the plant. He applied his idea practically by constructing various types of an apparatus he called the electro-végétomètre. This consisted of a head of metallic points raised in the air in the manner of a lightning conductor, and connected by a flexible conductor to a movable iron bar terminating in a series of discharge points just over the plants to be electrified. Atmospheric electricity is then collected by the upper end of the structure and discharged on to the plants from the lower end. Bertholon stated that the use of this apparatus was invariably accompanied with an improvement in the appearance of the vegetation, and with an increase in the fertility of the plants, &c. Grandeau‡ (1879) attempted to demonstrate the importance of atmospheric electricity by showing, by measurements, weights, and quantitative analysis, that when the plant was protected by means of a wire cage its leaf and stem development was greatly retarded. On the other hand Ch. Naudin, about the same time, published experiments carried out in the same manner, in which the plants left exposed to the open air had not grown so well as the ones protected beneath a wire cage.

The application of atmospheric electricity to stimulate plant growth, Mr. Priestley continues, has been a fairly common practice in France since Bertholon's time, some modification of what is termed the Géomagnétifère system being adopted. A lightning conductor is raised in an exposed position to collect atmospheric electricity, and this is connected with wires running through the earth under the plants it is desired to stimulate. With this method good results are claimed, though *Lord* Kelvin's suggestion is perhaps worthy of note, viz., that possibly the value of the treatment lies in the upturning of the earth necessary to plant the wire.

M. Pinot de Moira has used the system for several years in his garden in Clifton, always with favourable results; he has also shown the author rows of peas planted beneath a wire cage which were far less advanced than the control rows outside the cage.

Recently a great deal of work has been carried on in France, at the station for Agricultural Chemistry established at Meudon, by Prof. Berthelot,¶ who has tried the effect of the silent discharge, and particularly of atmospheric electricity upon plants. He compared the growth of plants at the top of a 28 metre tower with that of plants growing at the foot, and considered that greater growth at the higher level was largely due to the potential gradient in the atmosphere.

Electricity has been applied in a different way by Barrat in France, and Speschnew in Russia. In their experiments metal plates were sunk in the ground with a current passing through the soil between them, and apparently this stimulated the plants in this part of the soil to more vigorous growth than the plants on either side in the control plots. Speschnew‖ obtained his current simply by using plates of different metal connected by a wire, the small earth current thus obtained apparently proving amply sufficient to produce a marked result.

Rawson and Le Baron§ have used the same method at Arlington, Mass., quite recently. The plates of copper and zinc joined by a wire are sunk at either ends of forcing beds in the greenhouses, and are said to be very efficacious in bringing on lettuce at an early time; in fact, they state that the lettuce thus electrified was ready for the market a week earlier than that in the control beds. The potential difference between the plates was about 0·5 volts, and the current flowing varied from 0·4 to 15 milliamperes approximately.

Prof. S. Lemstrom* used the method of overhead discharge in a great number of experiments which he has conducted, and which were often upon a very large scale. He usually employed an influence machine of special construction driven by some continuous source of power; one pole of this machine was earthed, while the other was connected to a system of wires stretching over the plants and studded with fine discharge points. His results show a definite increase in yield in the case of many crops, whether the overhead wires were kept positively or negatively charged. The current was applied sometimes at night, sometimes in the day time, with apparently equally satisfactory results. Lemstrom points out in his book that precautions have to be taken in using his method of electrification, as in dry weather the electric discharge may easily be given for too long a time, when its effects are deleterious, also the treatment should vary according to the plants experimented upon, strawberries, for example, usually showing a very marked increase, whereas beans with the same treatment may often show considerable retardation in development.

At the Clifton Laboratory Dr. E. H. Cook† has carried out experiments the results of which seem to point to an increased power of germination, either with the use of low-tension currents (up to 20 volts and current passing up to 100 milliamperes) or with high-tension discharge from a Wimshurst machine. Apart from the increase in rapidity of germination, Dr. Cook was unable to satisfy himself that the passage of the low-tension current through the soil made any difference to the plant. Using the overhead discharge from the Wimshurst (E.M.F. from 25,000 to 40,000 volts) or from an induction coil (E.M.F. approximately 45,000 volts) he obtained a continued increase in the rate of growth of the plant.

Asa S. Kinney,‡ in 1898, and Ahlfvengren,¶ a year later, both found that the germinating power of seeds is apparently increased by an electric current passing through them. Kinney concluded that the optimum voltage for this current was about 3 volts. Ahlfvengren suggested that this optimum varied for different plants, and, also, with changing conditions, varied for the same plant. Results such as these would explain the different action of the current upon two different species, for one of them the voltage supplied may be optimum, whilst for the other it may approach the maximum, when it might exert a deleterious influence on the plant.

Lowenherz‖ seems to have come to similar conclusions; he also finds that the effect of the current on the plant is greatest during the period of germination. He is of opinion that the direction in which the current traverses the seed is of importance.

Large Scale Experiments.

This part of Mr. Priestley's Paper is of extreme interest. He commences it with a reference to the small trial apparatus with the overhead discharge system which Mr. J. E. Newman was able to instal during the winter of 1904 at the Golden Valley Nurseries at Bitton, near Bristol. The installation was completed by the spring, and, apart from occasional breakdowns, was running until the autumn. The breakdowns were accounted for by the fact that the machine used to generate the necessary electric power was simply a small influence machine of the Wimshurst type, hardly suited to continuous running, and that the oil engine first employed to drive it was scarcely powerful enough. The machine was working beneath a dust-free case in a small shed upon the grounds, and its two terminals were connected—one to the earth, the other to a system of wires running out over the grounds and through seven of the fifteen glasshouses. In the open the total area

of experimental and control plots was about a thousand square yards. The wires ran at a height of some 16 inches above the tops of the plants, or above the rows of tomatoes in the glass-houses, and upon these wires at intervals were twisted short pieces of fine wire with the free ends pointing downwards, and thus acting as discharge points. The wires were supported on ordinary telegraph wire insulators, which proved satisfactory except in wet weather, when there was such a rapid leakage of the charge that there was practically no discharge on to the plants.

From March 7th up to July 26th the machine was running during 108 days for a period of 9·3 hours daily. Until May 20th the machine was running chiefly in the day time, and after that date it was running principally at night. In all cases control plots were provided, which, apart from the electric treatment, were, as far as practicable, under identical conditions. The crops from the electrified and control plots were gathered and estimated separately, usually by weighing. The results of electrification in the case of the various crops grown were as follows :—

Cucumbers, 17 per cent. increase.
Strawberries (5 year plants), 36 per cent. increase.
,, (1 year plants), 80 per cent. increase, and more runners produced.
Broad Beans, 15 per cent. decrease, but ready for picking 5 days earlier.
Cabbages (Spring), ready for picking 10 days earlier.
§Celery, 2 per cent. increase.
Tomatoes, no difference.

One point requires special mention in the case of the cucumbers grown in the houses. On May 8th a spot disease, of bacterial nature, appeared in all the cucumber houses, and unquestionably made far more headway in the unelectrified houses. It seems probable that the ravages of the disease were largely inhibited by the electric discharge, for during one week when the influence machine broke down the disease progressed far more rapidly under the wires, and was again checked upon restarting the machine.*

The action of the electric discharge may be due to one of two causes, either the resisting properties of the host have been increased, or the attacking power of the parasite diminished. Recent work by Massee,† by Ray,‡ and by Miyoshi¶ supports the view that the greater immunity of the treated cucumbers might be due to chemical changes occurring upon electrification. Their investigations seem to show that the immunity of a plant to disease depends mainly upon the nature of the chemical substances in the cell sap in the tissues exposed to infection. This view of immunity is also supported by recent work upon the biologic forms of parasitic fungi found in the Uredineæ|| and Erysiphaceæ.§ In the bleaching of flour by means of the brush discharge, a toxic action of the discharge upon the micro-organisms present has been noted, but if this were operative in the case of the cucumbers one would have expected the disease to have appeared later, or not at all, in the electrified houses, whereas it appeared simultaneously in all the cucumber houses. The author finds it difficult to believe that when once present the bacteria within the leaf suffer more from the direct action of the current than the leaf itself.

During the whole period of the Bitton experiments Mr. Newman stated that, apart from the difficulties with the influence machine and oil engine, the electrical installation gave very little trouble, and only required attention in keeping the wires clear of cobwebs, stray shoots, &c.

A somewhat similar installation was working during the same year over a vegetable garden in Gloucester. Here a somewhat higher voltage was given by the influence machine, and the discharging points were kept 5 ft. above the ground instead of 16 in. above the tops of the plants, as at Bitton. With the crops under electrification —

Beet showed 33 per cent. increase;
Carrots showed 50 per cent. increase; and
Turnips showed an increase—not determined quantitatively, because of the destructive ravages of slugs on both crops.

§ The small increase in the case of the celery may be connected with the fact that in this case the wires used as discharge points were not so fine. As a consequence the amount of current flowing from the air to the ground was probably considerably less. In all the other cases fine wire was used for the discharge points.

The amount of sugar in the beets was determined at the College.

The unelectrified yielded 7·7 per cent. total sugar.
The electrified ,, 8·8 per cent. ,, ,,

Considering the total increase in the root crop, this suggests that this method of electrification may find a valuable field of application in the cultivation of the sugar beet.*

The results of some small trials with wheat that were made at Gloucester were very favourable, and arrangements were made by Mr. Newman to try the effect of the overhead discharge system upon wheat and barley on a larger scale.

Thanks to the interest taken in the work by Mr. R. Bomford, of Bevington Hall, near Evesham, Mr. Newman was enabled to use some 40 acres of this estate for experimental work in 1906, and experiments were commenced on this ground in the spring of that year, and are still being continued. Some 20 acres of this ground were beneath the discharge field, and as it was necessary for practical purposes to have the discharge wires at a considerable height, the very high-tension current required was obtained by means of an induction coil and valve rectifiers upon the system devised and patented by Sir Oliver Lodge, who very kindly lent the necessary apparatus. It was very largely owing to the generosity of Sir Oliver Lodge, and the advice and help of Mr. Lionel Lodge, that Mr. Newman was able to complete successfully the necessary installation and to carry out the experiments.

As it was, owing to the late delivery of some of the apparatus, the work had to be carried on with a somewhat improvised generating station at the commencement on March 16th; by the end of May, however, the installation was completed, and worked fairly continuously during the rest of the season, the current being applied intermittently until July 10th, by which date the wheat had been in ear about a fortnight.

The complete arrangements for generation of the high-tension currents are as follows :—

Direct current, about 3 amperes at 220 volts, is generated by a dynamo, driven by an oil engine of about 2 h.p. The current passes from the dynamo through the primary of a large induction coil with a make and a break contact interposed in the circuit. From the secondary of the coil the high-tension current was passed through the rectifiers, and then the one pole connected to the system of overhead wires, the other pole being earthed. The overhead system of wires covered about 19½ acres of ground. The wires were mounted on insulators placed upon larch poles some 15 ft. high, which were placed in rows, the rows being separated by a distance of 102 yards, and the poles in a row being 71 yards apart. Stout telegraph wire carried the current down each row; while thin galvanised iron wires, placed some 12 yards apart, were stretched between the rows and acted as the discharge wires. In this way 22 poles were sufficient to support the wire over the 19 acres. This acreage was spread over two different fields, in one field of which some 12 acres of wheat were under treatment, in the other 6½ acres of barley and a ½-acre plot planted with potatoes, mangolds, &c. The wheat field was of 19 acres extent: the remaining 7 acres (not under electrical treatment) were sown with English (White Queen) wheat, 1½ acres, and Canadian (Red Fife) on 5½. In the electrified part Canadian wheat occupied 3 acres, English wheat 9 acres.

The results on the barley field, including the smallplot, had to be neglected owing to the great local variations produced by the very irregular manuring the field had previously undergone. The wheat field, however, as far as one could judge, had been very uniformly treated previously.

In the wheat, difference was noticeable at an early stage—the young blades on the electrified part being, in the opinion of many observers, of a darker green. The crop was judged as considerably heavier by several practised observers, and the straw was on an average from 4 in. to 8 in. higher. Both experimental and control plots came into ear at about the same time, but the Canadian wheat under treatment was ready for cutting some three or four days before the control area. The crops were gathered separately from the electrified and unelectrified plots, and the resultant yields were as under :—

Bushels per Acre.

	Electrified.	Non-electrified.	Increase.
Canadian (Red Fife) ...	35½	25½	39 per cent.
English (White Queen) ...	40	31	29 ,,

Moreover the electrified wheat sold at prices some 7½ per cent. higher, several millers in baking tests finding that it

* Lomstrom. *Loc. cit.*, p. 47 and p. 55.

Digitized by Google

produced a better baking flour.† No theoretical conclusions can be drawn from this fact, owing to the uncertainty existing as to what factors determine the strength of wheat, but it is interesting to note that greater strength is usually accompanied by increase in percentage of total nitrogen.

Mr. J. Kirkland, of the National School of Bakery, Borough Polytechnic, found the evidence from baking tests supported by the average of dry glutens from all his tests thus :—

In the electrified	11·15 per cent.
In the unelectrified	10·35 ,,

The somewhat poor yield of wheat obtained from the unelectrified portion of the field is probably explained by a deficiency in lime, which has now been rectified. Further, the wheat was spring sown, and Red Fife, under this condition, does not usually yield good crops. The experiments are being repeated upon wheat during the present season, and strawberries are also under treatment once more.

Tests with Earth Currents.

At the College further trial has been made of the method of Barrat and Speschnew, in which plates of different metals are sunk in the ground and connected by a wire. Plates of copper and zinc were used with a copper wire soldered to them. The first trial was made with Vicia Faba, the beans being planted on February 21st, 1906; the control plants were grown between copper and zinc plates not connected with a wire.

The plants where the earth current was passing appeared two days earlier; in June they still showed markedly greater vegetative development, and though the total yield in the two plots could not well be compared, the average size and weight of beans differed in favour of the electrified plot, thus :—

	Electrified.	Unelectrified.
Average volume of bean ...	2 c.c.	1·5 c.c.
Average weight	2·26 grs.	1·71 grs.

Another series of experiments with beans was started upon May 25th, but in this case no difference in rate of germination was noted, while later the whole crop was so badly attacked by Aphis that further comparisons could not be made.

The following table shows the results obtained with other plants by this method :—

Wheat,	no difference.	
Barley,	Electrical,	matured earlier.
Maize,	,,	the weaker plants.
Cabbage,	,,	markedly better plants.
Radish,	,,	ready for pulling earlier.
Carrot	,,	larger, and with much more leaf development.
Lettuce,	,,	better developed plants.

The results are then inconclusive, though in most cases the plants where the current is passing have fared better. As an example of the strength of the currents used, with plates of area about 200 square inches, 4 ft. apart, a current of 12 milliamperes was passing, the soil being very damp.

Action of Current.

The author concludes his Paper by giving an account of some of the theories advanced to explain the physiological action of the current, and also describes some further experimental work, though the results of the latter were negative in character.

One suggestion, frequently made, is that the passage of water up the plant is aided by the electric current. Lemstrom advances this suggestion, and referred to experiments in which he had found that if a negatively charged wire is placed over a capillary tube which dips into water, the water climbs up the sides of the tube and collects in drops at a higher level. But if a positively charged pole is placed above the tube this did not happen, and with a positively charged overhead wire system he obtained the best results.

J. Chunder Bose‡ explains the rise of sap on the assumption of a pumping action of the living cells throughout the course of the xylem; the pumping action being a form of response to stimulus. If this theory is correct the current might be conceived as a stimulus giving rise to increased response, and therefore accelerating the flow of sap. The excitatory effects of kathode and anode are antagonistic, but with a current flowing through the soil, there would always be a resultant excitation of the root, because the kathode effect is always greater than the effect due to the anode.¶ But in the case of overhead discharge with the wires overhead negative, the leaves and stem would on this view be more stimulated than the root, and the result should be a tendency to pump water downwards. On the whole, then, it is difficult to make out a case for the rise of sap being aided by electric stimulation, and there is no experimental demonstration of its occurrence in the plant. Bose would more probably attribute the effect of overhead discharge to direct stimulus of the growth responses in the plant.

The acceleration of germination noted by so many observers obviously involves some different factor; the only possible explanation seems to be that the current is used by the seed as a source of energy,‖ this energy being directly used in anabolic process or in accelerating the katabolic processes of respiration.

Pollacci§ in a recent paper has suggested that the effect of a current passing through a green leaf may be to render carbohydrate synthesis possible from carbon dioxide and water, even when the plant is in the dark. Bach* has suggested that the electrolysis of carbonic acid might result in the formation of formaldehyde in the neighbourhood of the kathode, but he advanced no experimental results in support of this view. Euler,† as the result of practical investigation, found it impossible to obtain formaldehyde in this way. Waller‡ has detected the presence of small electromotive forces in a green leaf exposed to the light, but they are only found in a living tissue, and chloroplasts are necessary for their occurrence, no current being detected in a living petal exposed to the light.

The experimental evidence that Pollacci brings forward is based chiefly upon the presence of starch in leaves kept in the dark, with a current passing through them. Control leaves, also kept in the dark, contained no starch.

Before the author was aware of this work, he had, in conjunction with Miss D. Johnson, investigated the same point, at first with results which seemed to confirm those of Pollacci. As the result of further experiment, however, they were not able to demonstrate starch in an electrified leaf, if that leaf were quite free from starch at the commencement of the experiment. The presence of the starch in the earlier experiments seemed to have been due to the inhibition of the normal transformation of starch into sugar, owing to the excessive strength of current used. The experiments were made with Elodea, with Geranium and Coleus leaves, and also with green filamentous Algæ, such as Spirogya and Cladophora laid across platinum electrodes; the voltage used varied from 1 to 40 volts, above 40 the effect was usually fatal. With the object of ascertaining whether starch were produced by the action of the silent discharge in the dark, Mr. Newman kept plants beneath the discharge points at Bitton during a continuous run of 27 hours, and the leaves were afterwards picked and examined. No starch was found in them. The author is, therefore, unable to accept Pollacci's conclusion that starch can be formed by a green plant in the dark if an electric current of suitable strength be passed through it.

It has also been suggested that the effect produced on the soil by the electric current may be beneficial to the plant. Electrolysis undoubtedly takes place, and Dr. Cook found the soil slightly acid near the anode, and alkaline near the kathode, in some of his experiments. Ewart¶ suggests that the current increases the rate of solution and absorption of the insoluble food constituents present in the soil, but as the amount of electrolysis proceeding is not likely to make the soil locally very acid I do not see that this is likely to be the case.

Finally, there is the possibility that in the case of the overhead discharge, oxides of nitrogen are formed by oxidation of either the nitrogen or ammonia present in the air. Samples of the soil from the electrified and unelectrified parts of the wheat field in the Evesham experiments were analysed at College, the samples having been taken in the autumn after both crops had been gathered. They showed :—

Electrified	0·159 per cent. on dry weight.
Unelectrified	0·056 ,, ,,

But it is impossible, the author says, to draw conclusions from isolated analyses of this kind; however, following up this sug-

gestion, it is intended to keep a continuous check upon the soils by analysis during the present season.

Berthelot‖ considers that the clue to advantage of the electric discharge is to be found in an entrance of atmospheric nitrogen into the plant metabolism, but suggests that this is due not only to the formation of oxide of nitrogen, but also to the combination of gaseous nitrogen with carbohydrates within the plant.

CATALOGUES AND PAMPHLETS RECEIVED

ANTI-VIBRATION FOUNDATIONS.—A leaflet from Mr. F. J. Down calls attention to a system of foundation cushions invented by a civil engineer of Paris, the object of which is to prevent vibrations being communicated from running machinery to buildings by interposing an elastic bed. It is claimed that this special form of foundation absolutely breaks up the vibrations, and that the twisting movements produced by sudden variations of speed are absorbed without shock. The arrangement, which is known as the Praché non-vibratory foundation, is in use in a number of installations of electrical machinery in or near London.

ELECTRIC HEATERS.—An attractive show card illustrating some of the types of heaters supplied by Simplex Conduits, Ltd., has been issued. The card is so constructed that the portions illustrating the luminous parts of the radiators are translucent, so that a very striking effect can be obtained by putting a small incandescent lamp behind the card. A leaflet giving prices of these radiators is also to hand.

ELECTRICITY IN MINES.—A handsomely produced pamphlet with the above title is being circulated by the British Thomson-Houston Co. A short introduction recapitulates the advantages presented by electrical methods for mining, and speaks of the extensive experience which the company have had in meeting requirements of this nature, the reality of which is convincingly brought home by a series of illustrations showing a great variety of electrical mining work already carried out.

PACKING.—A booklet sent us by Messrs. Turners & Manville describes the properties of the H. W. Johns-Manville Co.'s "Vulcasbeston" packing, some samples of which are also to hand. Considerable advantages are claimed for this packing over other forms. The packing is made in sheet, from which washers, jackets, flange-joints, &c., can be cut, as well as in the form of rope packing for piston rods, valve stems, &c. The material is prepared under hydraulic pressure, and is composed of long fibre asbestos, with which is incorporated graphite, and is heated with vulcanisable gums. It is claimed not to stick, so that joints can be broken and remade any number of times.

SOLDERING MATERIAL.—Pamphlets in English, French, and German relating to the special soldering materials known as "Fludor," which are particularly suited to electrical work, are to hand from Messrs. H. Classen & Co., of Berlin (Barbarossenstrasse 16), to whom all inquiries should be addressed direct, as the agency formerly held for this country by D. Joroslaw has been terminated.

TROLLEY WIRE SUSPENSION.—A pamphlet issued by the Consolidated Accessories Co. describes in some detail Mr. Pringle's patent tangential suspension for overhead conductors, and gives illustrations of the various kinds of fittings used for this system. The arrangement, which is in use on the Derby Corporation tramways, was described in full in ELECTRICAL ENGINEERING, Vol. II., p. 979.

VENTILATING FANS.—The Wilson Wolf Engineering Co., Ltd., of Bradford, have issued a preliminary pocket list of their continuous-current "Arctic" ventilating fans, which forms a summary of the new complete catalogue which they are about to issue. Some new improvements have been made in the design of these fans, the motors of which are now fitted with combined journal and thrust ball bearing, which allows of the fans to be run in any position without altering the construction. Some alterations have also been made in the design in the fan blades themselves. They are now of the open-blade type in the standard fan, which is claimed to discharge a much greater quantity of air than the box-bladed type formerly used.

Faraday Society.—In consequence of the illness of Sir Oliver Lodge, the delivery of his presidential address, which was announced for last Tuesday, has been postponed until further notice.

An Automatic Transformer Switch.—The correct present title of the firm who manufacture the automatic transformer switch described on p. 440 of our last issue is Messrs. Knapton & Co., and not Messrs. Knapton, Bagnall & Co., as there described. A slight error appeared in the description of the instruments with reference to the connection of the shunt coil, which on the left-hand side is connected through the switch on the top right-hand side.

TESTS OF A LARGE TURBO-ALTERNATOR

BEFORE the third and fourth Brown-Boveri 3,500 kw. single-phase turbo-alternators at the electricity works, Frankfort, were taken over by the municipality last year, exhaustive trials were carried out, and the summarised results of a test on one of the units are given below.

Test Figures for Steam Consumption.

Steam pressure (lbs per sq. in.)	141·5	152·5	141	142
Steam temperature (deg. Fahr.)	455	470	461	498
Vacuum (Barom. at 30in.) ...	29·23	29·17	29·1	28·65
Output (includ. excitation) kw..	1542·4	2551·2	2586·3	3521·6
Steam consumption (lbs per hr.)	23734	35904	36519	47100
,, ,, (lbs per kw.-hr.)	15·4	14·08	14·15	13·38

The above turbines were built for a steam temperature of 300° C. (572° F.), but owing to local conditions it was not possible at the time of the tests to use higher steam temperatures than those given in the above table. Based on the results of many former tests, however, it is definitely known that an increase in the steam temperature of 5·7° C. reduces the steam consumption by 1 per cent., and it is therefore safe to give the following figures for the steam consumption of these plants at the steam temperature of 572° F., as follows:—

Steam Consumption reduced to a steam temperature of 572 deg. Fahr., and under the pressure and vacuum conditions given above.

Output (including excitation) kw. ...	1542	2551	2586	3521
Steam consumption (lbs per kw.-hr.)	13·65	12·7	12·6	12·4

It must be remembered that the alternators are single-phase machines, and consequently have a slightly lower electrical efficiency than the more usual three-phase machines. The condensing plant used for the above turbine is of Brown-Boveri manufacture, and the energy absorbed by it amounts to 2·9 per cent. when running at full load, and 2·5 per cent. when running at three-quarter and half load, at the vacuums indicated above.

Police Telephone Service.—Mr. Gladstone announced in the House of Commons on Friday last that out of the 192 metropolitan police-stations, 59, or over 30 per cent., are connected with the public telephone system. Also, 123 stations, or 64 per cent., are connected by the police telephone system.

Reduction in London-Paris Telephone Rate.—We understand that two new channel telephone cables are to be laid, and that the charge for a three minutes' conversation will be reduced from 8s. to 5s. The negotiations with the French Government concerning these improvements are not yet complete, but it is hoped that the new cables will be available for public use next year.

Wireless Telegraphy.—Wireless telegraph stations are being established along the Benadir coast; the chief station at Mogador will have a range of about 1,800 miles, and may be able to communicate with India. The Mogador stations will communicate with the stations at Asmara and Pisa. A wireless telegraph station has been established at the new Admiralty building, Whitehall, in order that communication may be maintained between the Admiralty and either the coast ports or the fleets in the Channel and the North Sea.

Smoke Nuisance.—The Metropolitan Borough Councils have received a communication from the London County Council, explaining that the Public Control Committee of that authority have had under consideration the question of obtaining an amendment of the law with a view of dealing more effectively with nuisance from smoke, and giving particulars of a draft scheme of amendment. The scheme lays down that dense smoke discharged from any building, vessel, stationary or locomotive engine, or premises (other than a private dwelling-house), within an area of twelve miles from Charing Cross, shall be a nuisance for which a fine not exceeding £10 may be imposed, with cumulative penalties for subsequent offences, at the discretion of the magistrate. The scheme involves the repealing of exemption from liability to penalties implied or expressed in favour of Crown property or premises of electric power corporations. The London County Council would have power to make bye-laws, subject to the approval of the Home Office or the Local Government Board to bring under the terms of the penalty provision other instances of avoidable smoke nuisance than those mentioned, to prescribe and revise from time to time a standard of smoke nuisance, and to prohibit the adoption in new or reconstructed premises, of any furnace, grate or fuel-consuming apparatus of a type which shall have been proved, to the satisfaction of the Council, to produce an unnecessary amount of smoke. The Council propose to take power to expend money for promoting a knowledge of the principles of combustion of fuel, furnace and grate construction, and stoking, for encouraging study of the use of smokeless fuel, and for determining generally the best means of preventing smoke.

NEW ALTERNATE-CURRENT INSTRUMENTS

THE Paper read by Dr. W. E. Sumpner and Mr. J. W. Record at last Thursday's meeting of the Institution of Electrical Engineers was to some extent supplementary to two previous papers entitled "The Use of Iron in Alternate-current Instruments," and "New Iron-cored Instruments for Alternate-current working" (*Journal, Institution of Electrical Engineers*, vols. 34 and 36 respectively), and its object was to describe the instruments as actually made on the principles enunciated in these papers, and indicate some of their uses and properties. In recapitulating the general features which form the basis of the system employed, the fundamental difference between the series magnet and the shunt magnet was pointed out. When a magnet is series excited, by a current through the field winding, the flux which is produced depends upon the current and on the physical properties of the core, but is quite independent of the resistance of the winding. But if the magnet be excited by the voltage, the flux is controlled by this voltage, and practically does not depend upon the properties of the core.

With the shunt magnet the eddy currents caused in a small piece of brass do not affect the magnetism caused by the exciting voltage. In the construction of the wattmeters now to be described it is thus permissible, within reason, to use brass clamping-pieces in the neighbourhood of the moving system. With a series magnet, on the other hand, the eddies induced in a piece of solid metal affect the magnetism caused

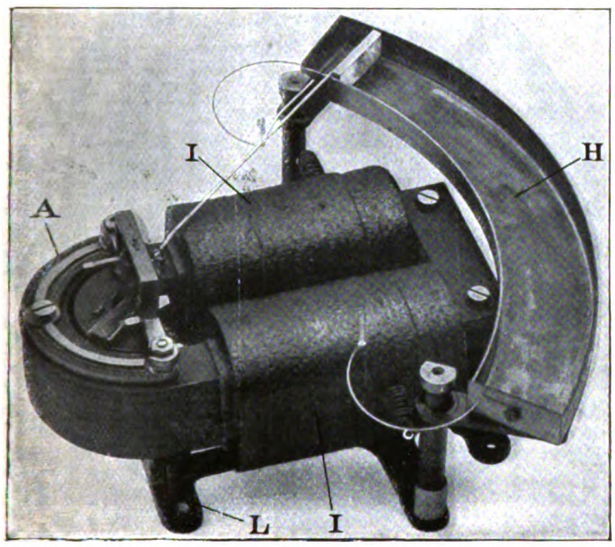

FIG. 1.—IRON-CORED ALTERNATING-CURRENT WATTMETER.

by the exciting current. The strength of the *series* magnet for a given current is dependent on the properties and the past history of its core. The field of the *shunt* magnet, on the other hand, is independent of the core, and is perfectly controlled by the voltage applied at the moment. It is not affected by any ageing effect in the core, and the field is thus even more reliable than that of a permanent magnet as used in direct-current instruments. The field of the shunt magnet, though caused by the voltage, is not in phase with it. Special means must be devised for supplying the movable coil with such a current as to make the deflection of the instrument a correct measure of the quantity to be tested. For the wattmeter a special form of current transformer is needed. For the voltmeter any ordinary condenser may be used. These accessories may be called quadrature transformers, since their function is to produce a moving-coil current which is in quadrature with the circuit current or voltage. The indicating instrument itself has the characteristics and advantages of permanent magnet instruments. Strong controlling springs can be used, and stray magnetic fields have no influence on the readings. The readings of the instrument are independent of frequency, and also of the wave-forms of the current and voltage. The field of the magnet when excited by a given voltage will be doubled if the frequency is halved, but the moving-coil current will at the same time be halved, so that the product which determines the deflection will be independent of frequency.

SHUNT-MAGNET INSTRUMENTS.

Structure of the Magnet and of the Moving System.—Almost any known form of electro-magnet which would permit a coil of wire to swing between two pole-faces could have been selected for these instruments, but partly on account of certain constructive difficulties it was decided to adopt the form of magnet with a single air-gap, shown in Fig. 1. The total

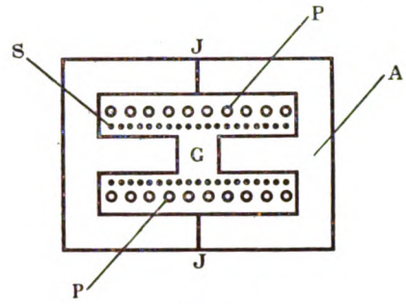

FIG. 2.

length of air-gap is only 0·08 of an inch, giving a clearance of 0·02 of an inch each side of the moving coil. This form of magnet has also been selected in order to reduce the magnetic reluctance of the circuit to a minimum, and to allow a large angular deflection of the pointer. The cross-section of the iron is about 1 sq. in., the total magnetic flux is approximately 32,000 C.G.S., and the flux density about 5,000 C.G.S. (R.M.S. values), at the normal applied voltage on 50-~ circuits. As the section of the gap is five or six times that of the iron core the flux density in it is correspondingly reduced. It is generally about 1,000 C.G.S. lines per square centimetre, and is comparable with that used in the air-gaps of good permanent magnet instruments. About 200 ampere-turns are needed to produce the flux under normal conditions. The moving-coil consists of about 40 turns of fine copper wire former wound, and fixed to an axle fitted with hardened steel pivots and supported between jewelled screws. The effect of temperature variations on the copper windings is swamped by the use in series of about 80 ohms of manganin wire wound non-inductively. An air-chamber *H* for damping down the oscillations of the pointer is provided, and the dial of the instrument forms the top of this dash-pot. The pointer *E* and damping vane *F* are placed so that their weight as nearly as possible balances the weight of the moving coil, thus the inertia of the moving system is not increased by the use of extra masses for balancing purposes. The torque on the moving-coil system is about 1·2 gramme-centimetres for 90° deflection, which is greater than that usually employed with instruments of the dynamometer or induction type.

The Quadrature Transformer.—In order that the instrument may read watts it is necessary to connect the electro-magnet in shunt across the mains, and to join the terminals of the moving coil to the secondary of a specially designed current transformer, which the authors designate a "quadrature" trans-

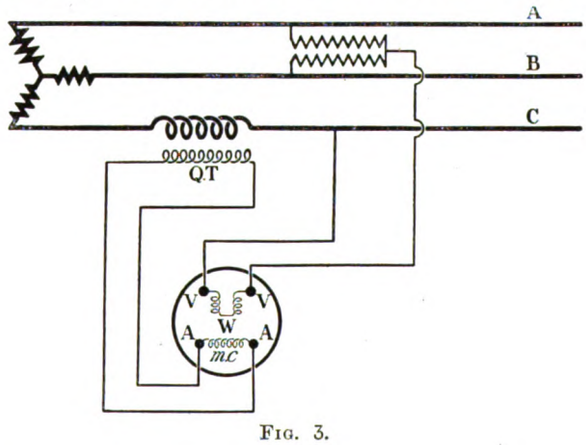

FIG. 3.

former. This transformer renders the current in the moving coil proportional to the current in the mains, and the product of the moving-coil current into the air-gap flux becomes a measure of the load whatever the voltage, current, frequency, or wave-form. The core *A* in Fig. 2 is formed of two blocks of iron stampings with butt joints at *J*, *J*, and an air-gap *G*,

Digitized by Google

generally about one-tenth of the length of the iron circuit. P is the primary winding, and S the secondary. The latter consists of a few turns of fine wire, the ends of which are joined through a high non-inductive resistance to the terminals of the wattmeter moving coil. It is this long air-gap in the

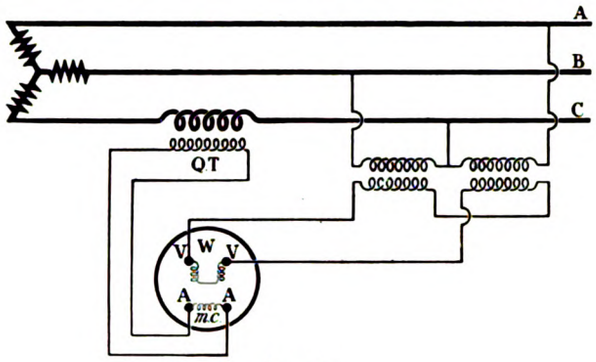

FIG. 4.

quadrature transformer that renders the flux proportional to the primary current for all changes in its value, and reduces the error due to hysteresis in the iron to a negligible quantity. For large currents two further types of quadrature transformer are made, one in the shape of a ring, to slip over cables, the other rectangular to slip over bus-bars. It is permissible, although not advisable, where series transformers are already installed, to connect the primary of the quadrature transformer in series with the ordinary current transformer secondary. The accuracy of the wattmeter will, however, be limited by the magnitude of the phase error of such series transformers.

Wattmeter Circuit Connections.—Fig. 3 shows how the instrument should be connected to the circuit for measuring the power of a 3-phase circuit, balanced load, when the neutral point is not available. A specially designed choking coil is used, with its ends connected to two of the mains, the wattmeter itself being joined to the third main and to the junction point of the choking coil. For high-tension circuits potential transformers are necessary to reduce the potential to a safe value for the instrument. Such transformers are connected with their secondaries in opposition in order to bring the voltage into proper phase relation with the current. The connections of this are shown in Fig. 4. One quadrature transformer only is used, and two potential transformers with opposed secondaries. An equivalent arrangement is possible, in which one potential transformer and two quadrature transformers are employed, the secondaries of the latter being parallel connected in opposition as regards the moving coil. The ease with which the wattmeter can be connected with, or disconnected from, the main circuit, without disturbing the latter, renders it suitable for a number of special purposes. For instance, the output of each of a number of alternators in parallel may be measured in succession by using *one* indicator and as many current transformers as there are alternators in parallel.

Magnetostatic Voltmeters.—The wattmeter may be used to

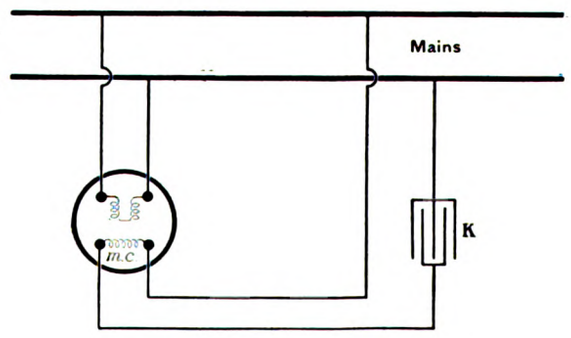

FIG. 5.

measure volts by changing the connections of the moving coil from the secondary of the quadrature transformer, and placing them in series with a condenser of suitable capacity across the mains (see Fig. 5). The readings will be correct on circuits of any frequency or waves form, provided the ratio of voltage to frequency is not made too great so that the resultant induction density in the iron is made excessive.

Portable Standard Voltmeter and Wattmeter.—The laboratory portable standard instrument is most useful, and the measurements to which it is adapted are so many and varied that it can be considered an alternating-current testing set. It consists of a mahogany case containing the movement already described, and is provided with four terminals and two switches. The internal connections can be traced from Fig. 7. It will be seen that with switch A in one position the coils of the electromagnet are connected in parallel, and the pointer will deflect to its maximum position for the rated voltage; and that with switch A in the second position the coils are connected in series, and twice that voltage will be needed to produce the same deflection. Switch B is for connecting the moving coil either in series with a condenser K across one of the field coils, or directly across terminals T and T_1. It will be noticed that the voltage applied to the condenser is the same for the same voltage per turn applied to the field coils, whether these latter or series- or parallel-connected. With switch B in the position shown in Fig. 7, the instrument is a direct-reading voltmeter having two ranges; the readings are quite independent of frequency, wave-form, hysteresis, stray magnetic fields, or electrostatic influences As the flux in the air-gap is proportional to the applied voltage, and the condenser current is also proportional to the applied voltage, it follows that the torque acting on the moving coil must be proportional to the square of the voltage. Two scales may therefore be fitted

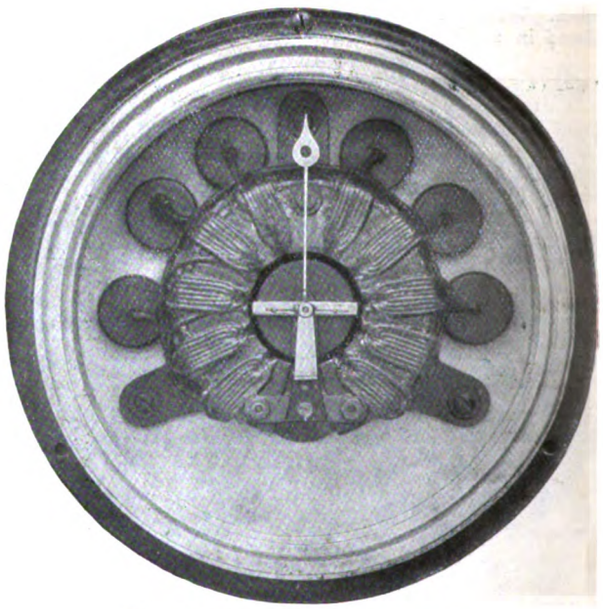

FIG. 6.—IRON-CORED PHASEMETER.

to the instrument, the wattmeter scale, having equal division, and the voltmeter scale, following a square law. A useful form of quadrature transformer for portable use consists of an ordinary quadrature transformer with a subdivided primary, the ends of which are taken to separate pairs of terminals, which can be connected in series or parallel.

Capacity Measurements.—When the switch B of Fig. 7 is turned to join the moving coil across T T_1, the instrument can be used for a variety of special purposes, one of the most useful being the measurement of capacity of cables and condensers. It is universally admitted that the present methods of testing capacity are both tedious and unreliable. The iron-cored voltmeter here described is essentially free from many of their defects. Any leakage current in the condenser, being in phase with the volts, is in quadrature with the magnetic field, and hence has no influence on the deflection, while changes of frequency and wave-form likewise cause no errors. The condenser fitted in the instrument for using this as a voltmeter can be also employed as a standard of capacity, and a special scale can be made for the instrument so that this is direct reading in microfarads for tests at any convenient fixed voltage. The readings on this capacity scale will be proportional to the readings on the watt scale, and hence proportional to the square of the readings on the volt scale.

INSTRUMENTS FOR PHASE MEASUREMENT.

Idle-current Ammeter.—For constant voltage circuits the wattmeter can be used as an idle-current ammeter. For single-phase circuits all that is necessary is to substitute for the quadrature

Digitized by Google

transformer a non-inductive strip resistance, to which the moving coil is suitably shunted; or, alternately, an *ordinary* current transformer with a secondary coil of many turns short-circuited by the moving coil. For 3-phase circuits it is only a matter of changing the connections of the potential leads.

Iron-cored Phasemeters.—Phasemeters are instruments analogous with ohmmeters, and the theory of their working is similar and almost as simple. The phasemeter is merely an ohmmeter, having, in effect, an alternating magnetic needle due to the flux caused by an alternating current traversing a moving coil, and having two alternating magnetic fields in fixed directions (but not in in the same phase) due to the cyclic currents through

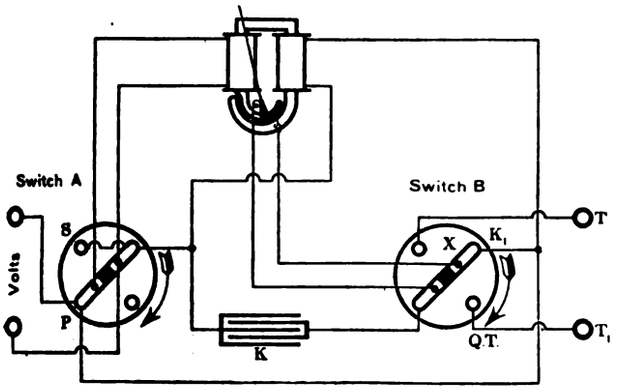

FIG. 7.

its fixed coils. Usually a phasemeter consists of a fixed and moving system of coils, one system containing two coils and the other only one. The instruments here described have only one coil in the moving system, but contain three coils, C_1, C_2, C_3, in the fixed system, the latter being traversed by currents representing A_1, A_2, and A_3, the three currents of the 3-phase mains. But these currents are necessarily such that one of them, say A_3, can always be regarded as the sum of the other two, so that the three coils, C_1, C_2, and C_3, just mentioned, can really be regarded as only two coils, having a portion C_3 in common, one of these coils being traversed by a current representing A_1, and producing the field OF_1, while the other is traversed by a current representing A_2 and producing the field OF_2. The directions OF_1 and OF_2 are approximately 90° apart, and this accounts for the total deflection of about 180° (90 for leading and 90 for lagging) to be found in most phasemeters. The three fields due to a unit current in each of the fixed coils are fixed in direction, as shown by OA_1, OA_2, and OA_3, in Fig. 8. The lengths of these lines denote the strength of the field due to a unit current in each case, this strength being determined by the winding of the corresponding coil. OF_1 is the resultant of OA_1 and OA_3, while OF_2 is that of OA_2 and OA_3. The currents A_1, A_2, and A_3, which actually flow through the coils, can be regarded as two currents only. One of them, A_1, traverses the first and third coils, and produces a field always along OF_1, while the other, A_2, traverses the second and third coils, and produces a field always along OF_2.

The introduction of the iron-cored phasemeter is a new departure in power-factor meters. A view of the interior can be seen in Fig. 6. The field magnet resembles the stator of a 3-phase generator built up with a number of iron laminæ. Instead of the rotor there is a fixed laminated iron core. This core forms one circular boundary of an annular air-gap, about ⅛ in. across, between itself and the outer stator. In this air-gap swings a moving coil, which is balanced and controlled by no other forces except those due to the interaction of the currents. The stator is wound for current, and for convenience is supplied from two series transformers, the primaries of which are traversed by two of the line currents. The moving coil has a high non-inductive resistance in series with it, and is placed in shunt across the mains. Various arrangements of transformers, analogous to those stated in connection with the wattmeter, may be used with the phasemeter.

Voltage-wound Phasemeters and Synchronisers.—A form of phasemeter is being developed, having its stator coils wound for voltage and its moving coils for current, the latter being supplied either from a shunt or from a current transformer. Experiments are also being carried out on an instrument of the above type, which has been so constructed that the moving coil is free to revolve continuously in either direction. By connecting the voltage windings to the bus-bars, and the moving coil to the terminals of an incoming machine, the phasemeter will be converted into a synchroniser. It will indicate if the incoming machine is "too fast" or "too slow" by revolving either clockwise or anti-clockwise. When the pointer comes to rest the speed will be right, and, by further regulation, the pointer will turn and become stationary in the normal position, and this will indicate the correct moment for switching in.

CALIBRATION AND ACCURACY.

Wattmeters and Voltmeters.—A simple direct-current test is used to determine the wattmeter scale. The same method may be used for the voltmeter, since the scale markings in the latter case are proportional to the square root of the corresponding scale markings in the case of the wattmeter. The instruments are afterwards adjusted on an alternate-current circuit against a standard instrument; for a wattmeter by an adjustment of the resistance of the moving-coil circuit, and for a voltmeter by the choice of a suitable condenser, followed by a final adjustment of the spring.

The error of an instrument in actual working is frequently more due to extraneous influences, such as friction or disturbing fields, than to incorrect electrical action on the moving system. From such disturbing influences the present instruments are well guarded, owing to the strong controlling springs used and to the natural shielding due to the iron employed in their construction. Moreover, the deflection cannot be influenced by eddy currents, which may be induced in the iron case or other metal parts near the moving coil. Numerous experiments have shown that the present instruments act correctly for changes in voltage, current, or frequency, and that the error for variations of power factor obeys the law applicable to all wattmeters, the error as a fraction of the true reading being given by $\theta \tan \phi$ where θ is a quantity characteristic of the instrument, and which may be conveniently called its *phase error*.

In Table I. below the wattmeter error for a phase error of 1 per cent. of a radian ($\theta = 0{\cdot}01$) is expressed in three ways for loads of different power factors.

Table I.

Wattmeter Error for a Phase Error θ of 1 per Cent.

Power factor, $\cos \phi$.	Per cent. of true watts, $100\,\theta \tan \phi$.	Per cent. of voltamperes, $100\,\theta \sin \phi$.	Millimetres on scale.
1·0	0	0	0
0·9	0·48	0·43	0·55
0·7	1·02	0·71	0·90
0·5	1·73	0·87	1·10

In the second column the error is expressed as a percentage of the true watts. The third column shows the error as a percentage of the volt-amperes, or of the watts associated with the same current and voltage on a non-inductive load. The last column expresses the error as a shift of the pointer in millimetres on the scale, assuming that a deflection measuring 5 in., or 127 mm., denotes a power in watts numerically equal to the volt-amperes.

For commercial purposes, the error is sufficiently small if kept

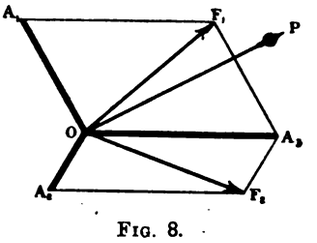

FIG. 8.

within a small fraction of the full deflection, and is always negligible if the corresponding shift of the pointer is within the error of reading under working conditions. In normal working full deflection is only attained for the circuit voltage at full-load current, when the power factor is unity. In the present instrument, if the phase error is 1 per cent., the error in the deflection is always less than 1 per cent. of the full deflection, however low the power factor, and that in nearly all cases it is less than 1 mm. measured along the scale.

The accuracy secured in the new instrument can be precisely indicated by the value of the phase error. In one of the portable standard instruments this value was only 0·0077 for 50-~ circuits, so that the corresponding errors are given by the numbers in Table I. when multiplied by 0·77. In one of the switchboard instruments θ was found to be 0·012 for 50- ~

Digitized by Google

circuits, corresponding with the figures in Table I. when multiplied by 1·2. The error of the electromagnet is due to the phase error represented by the ratio of resistance to impedance of the field coil (see *Journal*, vol. 36, p. 439). This ratio is about 0·4 per cent. for 50-~ circuits Two distinct ways have been found to precisely compensate the total phase error of the instrument for circuits of a fixed frequency. These methods have been amply tested and verified, but they have not yet been embodied in the commercial instruments.

The voltmeter is naturally less subject to error than the wattmeter, since the voltmeter is essentially the same as a wattmeter used on circuits of fixed power factor equal to unity. The deflection for a given voltage for a range of frequency of 3 to 1 does not vary as much as 0·5 per cent.

Phasemeters.—The theory and modes of calibration of phasemeters have been already discussed by one of the present writers (*Phil. Mag.*, January, 1906), and it has been shown that the phasemeters in general are much more accurate instruments on balanced loads than they are usually credited with being; in fact, phasemeters for multiphase circuits, if properly calibrated, are all alike in normal action, and differ only in liability to disturbances. Various makes differ, not in electrical, but in mechanical properties. The actual errors arising in working are due to causes extraneous from the electrical action of the instrument, being due to friction when the deflecting forces are weak, or to the influence of stray fields, or to the want of balance of the circuit currents. In the instruments here described the moving coil is perfectly shielded by the iron, and if this coil is out of proper position the rectifying forces brought into action are strong, so that errors due to the first two causes do not arise. All phasemeters are equally subject to error when used on unbalanced loads. A similar error arises in measuring the power of a 3-phase circuit by the single wattmeter method. The error which arises from such want of balance is determined simply by the ratios of the three currents in the mains, and is not dependent on the instrument employed. It is the same for all wattmeters and for all phasemeters, however good or however bad they may individually be. It is not serious except for low power factors and for badly balanced loads.

In an appendix to the Paper, an arrangement is described whereby a wattmeter may be used to measure the total output of a set of generators in cases where, owing to the sectionising of bus-bars and feeder circuits, it is not possible or convenient to so place a transformer that its primary is traversed by the total current. One indicator is required, and the same number of quadrature current transformers as there are circuits in parallel.

A further appendix describes a neutral point reactance coil, by the employment of which it is possible to use a single wattmeter to measure in succession the power corresponding with each phase of a 3-phase circuit. A quadrature transformer is needed for each of the three mains, and a light 2-pole 3-way switch. However badly balanced the main currents may be, the true power of each phase can be measured, and the wattmeter may be normally left connected with that phase which best represents the total power supplied to the load.

DISCUSSION.

Mr. SYDNEY EVERSHED (Messrs. Evershed & Vignoles) said he felt privileged in being the first to congratulate the authors on the progress they had made in developing this series of instruments which they had been at work on for nearly four years. One of the greatest drawbacks attending the use of iron for measuring instruments was hysteresis. With alternating-current instruments, of course, this disappeared, but there were other difficulties which remained unsolved. At one time he had believed it was possible to discover an iron which had no hysteresis, and in his young days he had read in a text-book that a certain mineral named magnetite, which existed in some remote part of Italy, had no hysteresis, or rather as it was then called no retentivity. Having gone to some trouble and expense to obtain a small piece, he had been disappointed to find that it had about as much corrosive force and hysteresis as very bad cast-iron. He then set to work upon the basis that the reason for hysteresis was molecular friction in the iron, and thought that if he could make iron fluid it would have no hysteresis. He therefore dissolved some iron in mercury, and made a kind of paste. But the result was also disappointing, because it was just as liable to hysteresis as any ordinary piece of soft iron, and it also had the disconcerting habit of spontaneous combustion. If he left this alloy of iron and mercury for a day without bottling it up, he found it reduced to mercury, generally in a pool on the bench, and a mass of black oxide of iron. Since then he had made many instruments, but he had never conquered hysteresis with soft iron, and he felt that the true application of iron lay with alternating-current apparatus, although he never really understood how it ought to be applied until he read Dr. Sumpner's Papers and saw his instruments. Since the early days he had spoken of, there was the work of Prof. Ewing, from which it was clear that it would never be got rid of. It was known that hysteresis was due to the proximity of the particles to each other, and not to the nature of the iron itself. He had ventured to praise the instruments a great deal, because he considered they were worthy of it; in fact, he admired the instruments more than the Paper. He confessed that, in reading the Paper, he found some difficulty in understanding some of the explanations. He rather felt that too many subjects were dealt with, and that not one of them was dealt with exhaustively. One point he noticed they had passed over very lightly, but he would like to hear Dr. Sumpner's explanation of how he got over the difficulty, if it existed, viz., the current induced in the moving coil circuit by the induction in the shunt magnet. That current was in quadrature with the induction, and therefore it had no torque on the moving coil, provided it was exactly at right angles to the induction, although it had a very considerable value. He had made a rough estimate of the electromotive force in the moving coil circuit, and found it to be something like 1·8 volts. Then he made out that the resistance of the moving coil circuit might possibly be as much as 100 ohms. This gave, for the induced current, something of the order of 18 milliamperes. As the current moving the instrument was only 4 milliamperes, this seemed at first sight rather alarming, and so it was until one remembered that it was out of phase with the induction and did not do anything towards altering the deflection. Then, from former Papers by Dr. Sumpner, he had found out what the impedance of the moving coil circuit might be, and had come to the conclusion that possibly the current in the moving coil circuit was not so entirely out of phase with the induction as to have no effect whatever. In fact, he came to the conclusion that it might cause quite considerable error if the same wattmeter was used for measuring watts on circuits of very different voltages. Possibly, the authors did not intend their instruments to be used for a very wide range of pressures, because they were intended primarily, he supposed, for switchboard use where the pressure did not vary very greatly. But he would like to know how that matter had been dealt with, because in designing ordinary wattmeters of the dynamometer type the electromotive force induced by the mutual induction between the two coils was a great nuisance. It was the bugbear in designing a dynamometer wattmeter, and it was one of the reasons why instruments in which the moving coil was kept in a position where the mutual induction was zero really had an advantage over deflection wattmeters, and, in his opinion, the Sumpner and Record wattmeter was the first in which this disadvantage had been removed. Dealing with one or two points in the Paper, Mr. Evershed first referred to the clearance between the moving and the pole pieces, viz., an air gap of about 20 mils. on each side. This seemed to him a very reasonable clearance; it was the same as was usually found in moving coil instruments for direct currents. It was within one millimetre of the amount used in the megger between the moving coil and the pole pieces, and it also happened, curiously enough, to be the same as he was using between the core of the armature of his little generator and the pole pieces. This was a case in point, because there also he was having a clearance between a laminated core made out of punchings and the pole pieces, and he found in practice that if the press tools for making the punchings were made in his own works, there was no difficulty in making the clearance 10 mils. if it were desirable. The only reason he did not was to avoid eddy currents in the pole pieces. He therefore thought the authors had brought their air gap down to a point below which it was not advisable to go. His next point was in connection with the authors' remarks as to how the volts scale of their combined instrument was obtained from the watts scale by taking the square roots. He thought that it was not sufficiently generally realised that every alternate-current instrument must have a parabolic law if it was going to be an ammeter or a voltmeter. Mr. Evershed then called attention to the authors' description of present methods of testing capacity as both tedious and unreliable, and proceeded to demonstrate by means of an instrument on the megger system, which he had brought with him, how quickly and conveniently capacity measurements, at any rate by this method, could be carried out, although the accuracy might not be of the laboratory order. Referring to phasemeters, Mr. Evershed said that, to his mind, the action of these was not described in the Paper in sufficiently simple language to enable people to get hold of the real principle involved. He then drew a simple diagram on the blackboard, representing a phasemeter by the sections of two fixed coils at right angles to one another and a moving coil perfectly free to move, the fixed coils being connected to suitable current and potential transformers. He showed how it might be regarded that the moving coil was influenced by the working component of the current of one of the fixed coils, and by the idle component of the current in the other, and thus took up a position corresponding to the power factor of the circuit. His last point he regarded as a rather serious one. The authors had devised an instrument which was independent of frequency, independent of temperature, and independent of power factor. But no instrument in the world

Digitized by Google

was independent of the English buyer, and the English buyer at the present time was exercising a very harmful influence on the design of instruments. He seemed to imagine that an instrument was a thing in which there were a few pieces of brass put in by the instrument-maker, and perhaps some more brass added by the sales manager. But if the buyer wanted a first-rate instrument, such as those described in the Paper, he must learn to pay for it like an honest man.

Prof. ERNEST WILSON (King's College) said he had one of these wattmeters, but before dealing with the practical points in connection with the instrument, he would like to compare its action with other methods of power measurement from a theoretical point of view. For this purpose he showed two diagrams, and directed attention first to one which was a reproduction of the diagram of connections of Dr. Sumpner's wattmeter from the paper, and proceeded to explain how the turning movement of the instrument, depending, as it did, upon the average value of the product of the current in the moving coil into the field, in which that coil found itself, would depend upon the integral of the impressed voltage, and also upon the differential of the current which was flowing in the work circuit. He also showed a few curves to illustrate these quantities, assuming that the voltage impressed, and the amperes flowing in the work circuit were true sine functions of the time. Prof. Wilson also exhibited another diagram, which showed a method of connecting up an electrostatic instrument for the measurement of power, which is often employed, and pointed out by a similar treatment to that used in the case of Dr. Sumpner's instrument, that this instrument had impressed upon its moving system and its fixed system two integrals, one of which was a quantity which might be called the rate of change of the amperes in the work circuit, and the other that of the impressed voltage. The point he wanted to bring out was that this instrument was not independent of frequency, and he showed mathematically that so long as the current and potential followed true sine functions, and so long as the frequency was absolutely constant, the electrostatic instrument, as he had shown it connected up, would act as a true wattmeter, and experiments showed this to be so. It could, however, be shown that the indications were not strictly accurate when the wave forms were anything but pure sine curves. He thought it worth while bringing forward this point, because it contrasted two important points of the problem, viz., the product of integrals and the differential and the product of two differentials. In the electrostatic case there was not a perfect instrument, whilst in the case of Dr. Sumpner there was a perfect instrument. He need hardly say that the electrostatic instrument could be turned into a perfect instrument, if one of the differentials could be turned into an integral. It was easy to turn the differential of the current into an integral by placing a condenser across the secondary of the transformer, and replace the quadrature transformer by an ordinary transformer. There would then be a potential difference impressed on the quadrants of the instrument proportional not to $\frac{da}{dt}$ but to $\int \frac{da}{dt}$, and then the equation of motion would satisfy the conditions laid down by Dr. Sumpner, and so obtain a perfect instrument. Dr. Sumpner was to be congratulated because he had been able to apply his knowledge of mathematics to a problem before making an instrument at all, and the application of his mathematics had convinced him that his instrument would be accurate when he made it. Owing to the shortness of time, Prof. Wilson was prevented from discussing the practical points which he referred to at the commencement of his speech.

Mr. K. EDGCUMBE (Messrs. Everett, Edgcumbe & Co.) wished more Papers of this class were read before the Institution. The feeling seemed to be held that it was unsportsmanlike to describe one's own inventions at the Institution, but he could not see it. He rather differed from Mr. Evershed in that he admired the Paper almost more than the instruments, but possibly that was because he did not make them. He thought that in some respects the authors had been led away by their enthusiasm for the virtues of the instrument to overlook the virtues of the dynamometer pattern. Mention was made several times of the fact that these instruments were free from disturbance by stray magnetic fields. This, however, applied equally to the astatic form dynamometer. Then, again, the quadrature transformer, which formed an integral part of these instruments was, he should say, anything but free from disturbance from stray fields. It was true that the instrument was shown surrounded by an iron core, presumably to shield it from stray fields, but it seemed to him that the shield might just as well be placed round the current coil of the dynamometer. In that case the instrument would be just as free from stray fields as the authors' particular instrument. The authors very rightly pointed out the disadvantages attending the use of iron cores in the current coils of wattmeters, but he noticed they used an iron core in their quadrature transformer. This would appear to be only transferring the errors from the instrument to the transformer. He was very glad to see the authors inveigh against the indiscriminate connection of any number of instruments on one transformer. This was a thing which all instrument makers would agree in discouraging. At the same time he did not know that he could go as far as the authors, and say that nothing ought to be connected to the transformer but the wattmeter. If the transformer was 800 to 1,200 ampere turns, there was no objection to connecting an ammeter or even an induction relay on to it. He would object to a solenoid relay, in which the back E.M.F. was very high and variable, to a large extent depending on the position of the core. He did not know that he could quite agree with the authors' way of rating instruments. As far as he could see, in the case of an instrument built for 10 amperes and 100 volts, they would graduate the scale to 1,000 watts, *i.e.*, the product of the maximum current and the maximum voltage. He did not think this advisable in view of the power factors met with in practice. He generally reckoned that the actual reading was only one half, but he noticed the authors gave the accuracy as a percentage of the volts and amperes, whereas he thought the accuracy ought to be given as a percentage of the maximum scale reading in watts. The whole question of rating wattmeters was an important one, and he hoped the Standards Committee would deal with it. He hardly thought the accuracy aimed at with the authors' portable standard wattmeter was quite sufficiently high for ordinary laboratory standardising work. They spoke of an error in the instrument itself of half a degree as being very good, but to this he presumed had to be added the error of the transformer. Again, he thought it a disadvantage with standard wattmeters not to be able to test them with direct current. It always seemed to him very essential, in the case of a complicated instrument like a wattmeter—not complicated in itself, but having to perform complicated functions—that it should be capable of being easily checked on direct current. He thought the Paper had brought forward some excellent ideas, which were applicable to other instruments than those described.

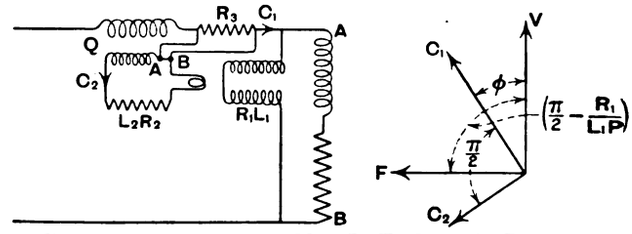
Prof. GISBERT KAPP (Birmingham University) wished to add his expression of admiration, not only for the Paper, but also for the instruments. He had tested an early pattern of the instrument, and found it very accurate, considering it was almost the first instrument made by Dr. Sumpner. It had a few faults, but he would rather call them faults of imperfection than faults of system, because Dr. Sumpner was not an absolutely perfect workman, although he was a perfect mathematician. He had found that the instrument was independent of frequency, after having tried it on several frequencies. The principle that Dr. Sumpner had introduced of using iron in such instruments as voltmeters and wattmeters was a step in the right direction. There were very good wattmeters which had no iron, but they took a large amount of power. Only the other day, in testing iron for hysteresis losses, he had found that the wattmeter might register five or six times the amount which could really be debited to the iron. It was not a serious matter in several thousands of watts, but in testing iron samples it was serious. He also thought it a very good thing to adapt these wattmeters to read capacity. Theoretically, it was possible to take the capacity and measure the charging current, but it was not possible to do much of this on a short piece of cable. It was then a risky thing to put on thousands of volts, and even if this were done it was hardly possible to measure the current. The authors had shown how it was possible to measure capacity to within something like $\frac{1}{10}$ microfarad. The method of measuring the charging current was also not very accurate as soon as they departed from the sine wave. But the authors were even independent of that error, because they had a standard condenser, and, provided that the E.M.F. wave did not alter its shape, then there was no error at all due to the departure from the sine wave. Finally, he would like to correct an impression that seemed to be about that no wattmeter was accurate for unbalanced loads. Perhaps what was meant was no wattmeter which measured the volts in one current, and asked for this to be multiplied by three. This was true, but there were wattmeters which were accurate upon unbalanced loads. He was reminded of the method by Behn-Eschenberg, in which two wattmeters were used to measure the unbalanced three-phase load. In this method, however, the wattmeters must not be too close together, or errors would be introduced. Recently, however, Messrs. Siemens & Halske had brought out a wattmeter, in which this error was avoided. It was too complicated to describe there, however, but he mentioned it in order that the impression might not get about that wattmeters could not be made from an unbalanced load.

Dr. C. V. DRYSDALE (Northampton Institute) congratulated the authors upon the beauty of the principle contained in their instruments, and the remarkable number of applications to which they were capable of being put. He would confine his remarks to the wattmeters which he regarded as by far the most interesting of the authors' instruments. Besides being beautiful in principle, it had the great advantage of being robust. He would ask them, however, to consider what the instrument really was. There were two kinds of electromagnetic wattmeters, those on the dynamometer principle and those on the induction principle, and he thought the instrument of Dr. Sumpner was really an induction wattmeter in a new form. In tracing out a diagram of an ordinary induction wattmeter upon the blackboard, Dr. Drysdale compared the shunt wind-

Digitized by Google

ing with the shunt magnet in the authors' instrument. Similarly, the disc, or cylinder, when eddy currents were introduced, was, in reality the quadrature transformer of the authors. He thought they were undoubtedly induction type instruments, in which the induction took place outside instead of inside. When this was realised, it smoothed away all difficulties and theories, and they really found that this new instrument was an old friend. This being so, it was interesting to consider what were the advantages and disadvantages as compared with the ordinary induction instrument. The first important advantage, that of the inclusion of a large manganin resistance in series with the moving coil, the temperature difficulty could be eliminated; another advantage was that by having the transformer in the position indicated with a large number of fine turns on the secondary, and also by having a moving coil, it was possible to switch over from one circuit to another in a manner not permitted by any other type of wattmeter. A third advantage was that, by having the circuits independent, it was possible to introduce the pretty principles of condenser measurement referred to. Considering the disadvantages, he thought that, after all, the instrument must be regarded as an induction pattern wattmeter, spoilt by additional complexity. The original induction wattmeter was one of the simplest of all instruments, because it happened to have almost everything needed on an instrument. One disc served for three things; it served as the coil; it served for the interconnection of the two magnets, and, by putting a damping magnet on the back, it was possible to obtain all that was necessary in such an instrument. If it were not for the temperature variation, he thought they would have to say that the induction instrument in its old form was better. It was certainly cheaper and extremely effective and simple. He had himself endeavoured to improve the dynamometer wattmeter as a defectional instrument, and the only way of doing this was to put in iron. In his opinion the best place for the iron was in the series circuit, to keep it out of the shunt, and thus preserve the dynamometer principle. The authors were really measuring these things as the product of $\frac{dA}{dt} \int Edt$, whereas all that was wanted was to simply multiply the amperes by the volts. Clearly, it was preferable to stick to the original instrument if it were possible. The independence of frequency could only go over a certain range—a very considerable one, he agreed—but not extending to no frequency at all, *i.e.*, direct current. It was an advantage to be able to check on direct current, and all that was wanted was to take great care that the ratio of the amount of iron in the circuit was not too great for the air in the gap. He had made an instrument on this principle, of the iron-clad type, with a very simple moving coil, which was fairly accurate and very cheap to construct. Further, they had only to put two systems at right angles on the same shaft to get the Behn-Eschenberg arrangement for a three-phase wattmeter.

Mr. J. T. IRWIN referred to the method of compensating for the errors in the wattmeter mentioned by Dr. Sumpner. He had brought the method to the notice of the author of the Paper a short time ago, but Dr. Sumpner had found, on looking up his notes, that it had also occurred to him. It is required to measure the power given to the circuit AB. R_1 and L_1 are the resistance and the effective inductance of the magnet coil; L_2 and R_2 are the inductance and the resistance of the moving coil circuit. M is the mutual inductance of the two coils of the quadrature transformer, and R_3 is a small resistance inserted in the main circuit. The vector diagram shows the phases of the various quantities. V is the voltage across AB. C_1 is the current in the main circuit lagging behind V by the angle ϕ. F is the flux in the shunt magnet, which lags behind the voltage V by an angle equal to $\frac{\pi}{2} - \frac{R}{L_1 R_1}$ and is inversely proportional to the frequency. The current C_2 in the moving coil is at least $\frac{\pi}{2}$ radians behind the current C_1, and is directly proportional to the frequency. The angle between the flux and the secondary current is $\phi + \frac{R_1}{L_1 P}$ if the inductance of the secondary circuit is negligible. To make the angle between them equal to ϕ the current C_2 has to be advanced by an angle $\frac{R_1}{L_1 P}$. To do this all that is necessary is to open the secondary circuit at AB and join the circuit up through the resistance R_3 in the main circuit. There are now two E.M.F.'s in the secondary circuit MPC_1 and $C_1 R_3$, and the resultant E.M.F., if the resistance R_3 is joined up in the right direction is $\left(\frac{\pi}{2} - \frac{R_3}{MP}\right)$ radians behind the current in the primary. When $\frac{R_3}{MP} = \frac{R_1}{L_1 P}$ the wattmeter would be correctly compensated for the resistance of the magnet winding, and would read correctly on any power factor or frequency. Further corrections could be introduced to compensate for the small self-induction of the moving coil circuit, and for the iron (if any) in the quadrature transformer. Thus the total angle of lag of the current in the secondary circuit behind the flux in the magnet when there is no compensation is equal to



$$\phi + \frac{R_1}{L_1 P} + \frac{L_2 P}{R_2} + \theta.$$

where $\frac{L_2 P}{R_2}$ is the angle of lag of C_2 behind the E.M.F., and θ is the angle by which the flux in the transformer lags behind the main current. To compensate for these last two phase errors, it is necessary to increase the value of R_3 so that

$$\frac{R_3}{MP} = \frac{R_1}{L_1 P} + \frac{L_2 P}{R_2} + \theta.$$

When this is true the wattmeter will read correctly at any power factor for this one particular frequency. The resistance of the magnet will be correctly compensated for any frequency, but the phase errors, owing to the self-induction of the secondary and to the iron in the transformer will only be partially compensated for when the frequency is greater than this particular frequency. Of course, there will be over-compensation for a frequency less than the particular frequency chosen for exact compensation. For any practical frequency the phase error will be only a small fraction of the error when uncompensated, which Dr. Sumpner has shown can be made very small.

Mr. J. W. RECORD, in the course of a few remarks, dealt briefly with the points raised by Mr. Evershed, viz., hysteresis and capacity. He was very interested to hear that Mr. Evershed had tried fluid iron, although he had not met with much success. The same idea had occurred to him a short while ago, and he had thought of trying an electromagnetic instrument with some iron filings in a small tube or pouch. He had not carried out the experiment, but from Mr. Evershed's remarks he gathered that it would practically be no good. With regard to measuring capacity, there was considerable trouble with commercial condensers for about twelve months: he had had an ohmmeter connected up for measuring capacity, and one of his assistants had named it the capaciometer. But there were obvious objections. With a condenser of the roll type, there was a series of creases at regular intervals, *i.e.*, wherever the paper was bent. He was speaking of continuous plate condensers with one plate over another, and in addition

DIAGRAMS ILLUSTRATING MR. J. T. IRWIN'S REMARK.

to the creases already referred to, there were probably some others due to winding. If the capacity was measured on a ballistic galvanometer, it would be found that if this crease was nearly broken through, the current would begin to come in at one end and spread out at the crease and round, and so on at all the creases, although it charged the whole plate, and the usual deflection was obtained upon the ballistic galvanometer. If such a condenser were put upon alternating current, and measured by means of one of their instruments, it would be seen that although the condenser measured correctly on a ballistic galvanometer, it was really a bad condenser. He had confirmed this many times by comparing tests on several condensers. He had found nearly the best of condensers, as tested by ballistic galvanometers, to break down completely on the alternate current test, and on unwinding the condensers he had invariably found it was due to the breakage of the metal conductor in building up, or else due to creases in the winding of the plates. Regarding the errors in these instruments, broadly speaking, he thought they could be summed up into saying that it was better to have errors that were known than errors that were not known. In this wattmeter the error could be calculated and checked, and whenever that had been done, the calculated error came very close to the measured error, and it could be depended upon. Although it was not possible to check the instrument on direct current, it could be calibrated on direct current, and instruments so made had always proved perfectly accurate, both on alternate current and direct current.

Dr. SUMPNER intimated that he would send in a full reply to the *Journal*, but said that, referring to Mr. Evershed's remarks, his assumptions with regard to the E.M.F. induced in the moving coil circuit were approximately correct. He had gone into that question very fully in a Paper which had not yet appeared in print, but which had been accepted by the Royal Society, and Mr. Evershed would find every point he had raised dealt with there.

A vote of thanks was accorded the authors at the conclusion of the discussion.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

F. HABER has recently, *Chemisches Zentralblatt*, 1908, Vol. I., p. 1022, carried out experiments in order to ascertain whether, when porcelain becomes conducting upon being heated, it obeys Faraday's law. It is well known that when cold a piece of magnesium oxide or calcium oxide will not conduct the electric current, but when heated the current is able to pass, this principle being employed in the Nernst lamps. A piece of glass, also, which is considered to be one of the best of insulators, can also be made to conduct the current by heating it. For example, if two platinum wires are sealed into a glass rod, so that within the rod the distance between the two pieces of wire is about 1 cm., and the two free ends are connected through a lamp resistance with the 100-volt circuit, a milliammeter being in series, no current, of course, will pass. But if the glass rod is heated to redness, a deflection is shown upon the ammeter scale. The question in such cases is, with what kind of conduction are we dealing? Now glass consists of fused silica, sodium silicate, and calcium silicate. In such a case we may suppose the conduction to be somewhat similar to the conduction of aluminium oxide in fused cryolite. The silicon dioxide being ionised, just as the aluminium oxide is ionised. Now porcelain also becomes a conductor when heated. The porcelain will contain Al_2O_3, Fe_2O_3, CaO, KCl, NaCl, and $Mg_2P_2O_7$, but is, of course, mainly composed of aluminium silicate. Haber has actually determined the amounts of these oxides which are transported when the porcelain becomes heated, and is in an electric circuit.

His method of procedure was as follows. He took an unglazed porcelain crucible (Rose crucible), such as is used for determining sulphides, &c., in a stream of hydrogen. The crucible was filled with tin, and was also bedded in tin, which was contained in a steel crucible. The tin inside the crucible was made the cathode, that outside being the anode, and care was taken to keep the cathode out of contact with the air. The whole was then heated to 800-1,000°C., and connected up in a circuit of 55 volts. A current of 15 to 20 millimetres passing (4·5 milliamperes per square centimetre). The electrolysis was continued from 8 to 10 hours, at the end of which time contact was broken, and the whole allowed to cool. The cathode tin was then dissolved and analysed, and the transport coloumbs for Al_2O_3, Fe_2O_3, CaO, $Mg_2P_2O_7$, KCl, and NaCl calculated, the numbers being compared to those given by a silver coulometer. It was found that the numbers agreed very closely with the numbers required by theory, *i.e.*, the agreement with Faraday's law was good. At the temperature 800-900°, aluminium silicate appears to have very little to do with the transport of current, but CaO and MgO entered largely into the transport. The anode tin was also found to have penetrated considerably into the porcelain, which is another proof of electrolytic conduction. From 300° upwards porcelain shows electrolytic conduction, and from 300-900° the aluminium silicate which makes up the bulk of the porcelain is not a conductor, but acts simply as a solvent (in the solid state) for the alkaline oxides. The action is therefore somewhat similar to the solution of alumina in cryolite, although in this latter case we are dealing with a completely fused electrolyte.

When lead peroxide is electrolytically deposited upon carbon or graphite electrodes, the difficulty is to get an adhering deposit. A carbon electrode upon which lead peroxide has been deposited is very useful as an anode in the electrolysis of alkali chloride solutions, and for the production of hypochlorites or chlorates; it is, however, of course, essential that the peroxide coating should be adherent, otherwise it falls off into the bath and contaminates the product. According to the *German Patent*, 195117 (1908), of the Konsortium fur Elektrochemische Industrie, a perfectly adherent deposit can be obtained by, before hanging the carbon in the lead peroxide-producing bath, impregnating it with some substance which will fill in the pores. The impregnating substances suggested are paraffin or fats, solid fatty acids, ceresin, &c. The bath for the peroxide deposit consists of nitric acid and lead nitrate. The peroxide deposit is then obtained of such firmness and density that the electrode may be broken across without the peroxide flaking off, the break of the carbon and peroxide being coincident.

On March 5th we referred to the electrolytic production of hydrogen and oxygen by the process of the Elektricitäts-Aktiengesellschaft vormals Schuckert and Co. The particular form of cell which they employ is described in the *British Patent* 3,000 (1907). The apparatus, as is shown in the illustration, consists of screens which are used between the electrodes in order to keep the evolved gases separate, and the object of the invention is to provide means for obtaining pure gases or mixtures of any required proportion. The invention is based on the observation that gas, as evolved at the electrode sur-

faces, forms eddies whose diameter is proportional to the surfaces from which they are produced, and to the volume yielded per unit of time. The electrodes *a* and *b* are metallically connected to the bells *c* and *d* respectively, and from these bells the gases are led away by the pipes *g* and *h*. The screen *i*, if of metal, is insulated from the bells, and projects so far below the bells that the current lines do not touch them. Naturally, if the screen is of metal it is necessary to keep the voltage below the pressure which would cause the screen to become dipolar. By carefully proportioning the electrode surfaces projecting below the screen, practically pure gases can be obtained. For example, hydrogen and oxygen can be obtained having a purity of 98 to 99 per cent. It is possible to so adjust the electrodes with their integral screens that the gases may be generated in any desired form of mixture.

K. A. Kuehne, *American Patent* 878,210 (1908), describes a modification of the Goldschmidt Thermit Process. He recommends for the production of pure metals or metalloids in the fused state, which cannot be readily obtained by means of reduction with aluminium alone, the use of chlorates, perchlorates, or other substances which readily evolve oxygen. It will be remembered that in the original Goldschmidt process, barium peroxide was employed as the ignition powder. Kuehne proposes to employ larger quantities of the peroxide, in other words, to use a mixture of aluminium and barium peroxide as the reducing agent. Other peroxides, such as lead peroxide, sodium peroxide, or persulphates, may also be employed. In order to produce a readily fusible slag, so that the reduced metals may easily collect at the bottom of the crucible, a flux of fluospar and lime may be added.

Aluminium, it is well known, is only very slightly attacked by nitric and sulphuric acids, but most other metals interact vigorously with these metals. According to *Elektrochemische Zeitschrift*, of March, the German military authorities at Siegburg have been testing aluminium vessels for the last two years, to ascertain if they are really able to withstand the action of acids. It has been found that the metal is practically unacted upon by nitric and sulphuric acids, either dilute or strong. Also that a mixture of strong nitric and sulphuric acid, such as is employed for the manufacture of explosives, has very little action upon it. Aluminium vessels which have been used over two years with these acids were found still to be in good condition, and quite capable of extended use. It follows, therefore, that aluminium vessels can very well be used for working with either nitric or sulphuric acids.

ELECTRICAL SCIENCE

British and American

Electric Discharges Through Gases.—At the Royal Institution on Saturday last Prof. J. J. Thomson delivered the third of the course of lectures on this subject. The lecturer commenced by referring to the conductivity of a layer of ionised air (see report of last lecture, ELECTRICAL ENGINEERING, March 19th, page 444), and showed an experiment illustrating how the conductivity increased with increased thickness of layer. Prof. Thomson then described some experiments which had been made to determine the nature and character of the charged particles in an ionised gas. The speed of the particles under the action of a known force had been determined, and this allowed of their mass being calculated. The velocity of a positive particle in hydrogen at a pressure of one atmosphere, and under the influence of an E.M.F. of 1 volt per cm., was

Digitized by Google

6·7 cm. per sec.; of a negative particle 7·95 cm. per sec. For complicated gases the velocities were more nearly equal, but the velocity of the negative particle was generally greater than that of the positive particle. This was a lower velocity than that of a single molecule, so it was presumed that each particle was an aggregate of three or four molecules round a charged body, and there was one such particle to about a million ordinary molecules. As the conducting portion of the gas was heavier than the rest of the gas, it should be possible to separate out this portion, as it would liquety sooner than the rest of the gas. Ladenburg had frozen out an explosive product from ionised oxygen, which was probably an allotropic modification, perhaps 5 or 7 atoms to the molecule. Prof. Thomson had himself tried to obtain a similar product from nitrogen, but on account of the many impurities in the gas used these experiments had not been very successful. The lecturer showed by experiment that ionised air passed through a tube immersed in liquid air lost its conductivity. The velocities of the charged particles in a flame were very high the negative particles, according to E. Gold, attained to a velocity of 13,000 cm. per sec., or practically the calculated velocity of the negative corpuscles of the cathode rays. The positive particles in a flame had a velocity of only 80 cm. per sec. To illustrate this the lecturer showed an experiment in which the current was conducted across a flame between two metal plates. As practically all the current was carried by the negative particles, which were driven away from the cathode, practically all the E.M.F. was required at the surface of the cathode. At low pressures the negative particles appear to simplify, and after a certain pressure is reached the velocity of the negative particles increases rapidly.

The Scattering by Matter of the β-rays from Uranium.—The law of the absorption of β-rays by matter has been practically settled by the work of numerous experimenters. It is expressed by the formula

$$I = I_0 e^{-\lambda d}.$$

where I and I_0 are the intensities of the rays before and after passing through a layer of matter of thickness d and λ is the coefficient of absorption. If ρ is the density of the absorbing matter, then it is known that λ/ρ for the chemical elements is a periodic function of the atomic weight, the periods corresponding to the well-known periodic law of the elements. These facts concerning absorption of β-rays are now supplemented by J. A. Crowther's work on the scattering of β-rays. The research is chronicled in the March number of the *Proceedings* of the Royal Society. The observers of absorption have usually obtained the β-rays by covering a layer of radioactive matter by aluminum foil sufficiently thick to cut off the α-rays from the radioactive matter. The absorbing matter studied was then placed in the beam of β-rays coming from the aluminium plate, and the reduced intensity, as well as the original intensity, measured by the ionisation method. Of course, the β-rays falling on the absorbing plate arrive at all angles and pass through at all angles, because of scattering. The case is analogous to that where the intensity of the light transmitted through a ground-glass plate is being considered. The scattered light might be estimated in this example by placing a large number of small blackened tubes close together with their ends on the glass and with their lengths perpendicular to the glass. In this way the light leaving the plate normally, that is, the light not scattered, might be measured, and hence the scattered light computed. The present observer has followed this process exactly in his experiments on the scattering of β-rays. A large number of equal brass tubes, about 5 mm. diameter, are bound together, and such a bundle placed on each side of the absorbing plate. With this arrangement the greatest possible angle of incidence and emergence was about 9°. It was found that the intensity of the emergent β-rays was only 5 per cent. of the intensity obtained without the tubes in position. This enhanced the difficulties of measurement incidental to the ionisation method, so extremely thin layers of absorbing material had to be used. With gold there was complete scattering with a thickness of 2 thousandths of a millimetre, and with aluminium at 150 thousandths. The law followed by the intensities of the β-rays before and after transmission is given by

$$I = I_0 e^{-\sigma d}.$$

where d is the thickness traversed and σ is the coefficient of scattering. The ratio of the coefficient of scattering to the coefficient of absorption for the same material is practically identical for all the substances experimented upon, its value being approximately 13. From this it is clear that the value of σ/ρ, where ρ is the density, is a periodic function of the atomic weight of the elements.

Continental

A New Magnetic Detector.—An instrument based upon Sella's magneto-elastic principle is described by A. G. Rossi in the January number of the *Nuovo Cimento*. It consists of an iron or nickel wire in a magnetic field traversed by an alternating current and subjected to simultaneous tension and magnetic torsion. Incident wave-trains reduce the amplitude of the torsion and shorten the track of the spot of light cast by a small mirror attached to the wire. This circumstance paves the way for direct photographic registration. The wire has a diameter of 0·1 mm. and a length of 20 cm. Two bar-magnets, each 10 cm. long, are mounted parallel to the wire, both their N.-poles being near its middle and their S.-poles near its ends. The magnets are weak, and the alternating current very feeble. The torsional vibrations of the wire are attuned to the incident wave frequency. The wire from the antenna is brought to the centre of the stretched wire without touching it, and winds round it in two opposite coils. The main advantage of the new detector lies in the small mass—about 15 milligrammes—which prevents any transformation of the energy into undesirable forms, such as takes place in Marconi's magnetic detector.

Reception of Waves in Wireless Telegraphy.—An elaborate investigation into the conditions under which electric waves are absorbed is contributed to No. 3 of the *Annalen der Physik* by R. Rudenberg. His results emphasise the hopelessness of transmitting energy by wireless means in a quantitative manner. The dissipation is enormous even in the best systems. The amount of energy absorbed from a given wave is proportional to the square of its wave-length, so that there is a rapid increase of efficiency on lengthening the waves. On the other hand, the somewhat surprising conclusion is arrived at that the effective length of the antenna is without any influence upon the proportion of energy absorbed. This, however, does not appear to apply rigidly to a single vertical antenna. It does apply to the "umbrella" form of receiving antenna, whose effective length is about half the height, since downward currents along the ribs reduce the radiation from the vertical wire. The author gives some interesting diagrams illustrating the distortion of the wave-train by a receiving antenna. This distortion extends over about 24 wave-lengths. The area from which energy is absorbed has a radius equal to about one-fifth of the wave-length.

Electrolytic Detectors.—Several methods of increasing the sensitiveness of electrolytic detectors are studied by E. Branly in the *Comptes Rendus* for March 9th. These include heating, mechanical agitation, and bubbling of gases. With a positive electrode 0·01 mm. in diameter, the sensitiveness increases on heating as far as 80°, with a maximum at 60°. This effect is lost after several successive heatings, but is gradually recovered. Another expedient consists in mounting the cell on a carrier which slides to and fro about an inch, say, twice per second. The effect is well marked, but the noise of the motion necessitates a separate room in order not to interfere with the telephone observations. The best effect is obtained by bubbling gases through the electrolyte. Almost any gas will do. A good method is to produce the decomposition of water within the electrolyte itself by means of two separate electrodes and an auxiliary current. The effect so obtained persists for some time. The author has also obtained an increase of sensitiveness by arranging two electrolytic detectors in series and doubling the E.M.F. applied to them.

Sensitiveness of Selenium.—In the *Physikalische Zeitschrift* for March 1st, C. Ries discusses the means of enhancing the photoelectric sensitiveness of selenium. This sensitiveness is shown either in the solid conductor, which increases in conductivity on illumination, or in a galvanic cell, where illumination of the selenium electrode produces an E.M.F. As regards the former, the author finds that the best results are obtained by mounting the selenium layer first in the amorphous state, and subsequently getting it into the crystalline form by heating it slowly to 195°, keeping it at that temperature for half an hour, and then cooling it rapidly. The maximum resistance, with or without illumination, depends upon the temperature. In one cell the author found it to be 23°C. six years ago, and it is the same now. As regards the electrolytic selenium cells, their behaviour may be summarised by saying that the "photo-electric current" always passes in the direction of the beam of light which travels between the electrodes. Thus, if the selenium electrode is positive, illumination tends to charge it negatively, and reduces the current. Positive polarisation has a well-marked effect in increasing the sensitiveness, so long as it remains within 1 or 2 volts. Negative polarisation has a maximum effect at 0·5 volt, and then rapidly decreases and becomes negative.

New Telephone Charges.—At the annual meeting of the Association of Chambers of Commerce last week, a resolution was moved by Lord Brassey, and seconded by Mr. Bonar Law, M.P., expressing the hope that the Postmaster-General would modify the present system of charging for telephone service as applied to the needs and requirements of the commercial community in the provinces. The resolution was adopted unanimously, without debate. Representatives of the London, Sheffield, Dundee, Bradford, Southampton, Leeds, Hull, Nottingham, Birstall, Birmingham, Kendal, Newcastle, and Liverpool Chambers of Commerce were appointed a special permanent committee to confer with the Postmaster-General and the National Telephone Co., whenever necessary.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published March 19th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

1907 Patents

4,333, J. H. Webb. A method of wireless signalling by continuously generated electric oscillations. The oscillation generator is continuously operated, and the amount of energy translated to the radiating circuit is varied by different means. For instance, the inductive coupling between the oscillating and radiating circuits may be varied by causing the transmitting key to alter the relative positions of the coupling inductive coils in these circuits; or an additional translation circuit may be arranged, which will translate the oscillations from the oscillating to the radiating circuit, when it is brought into harmony with the oscillating circuit. In this case the transmitting key may vary the capacity of a condenser in the translation circuit so as to alternately harmonise and deharmonise the circuit. Seven claims, three figures.

5,506A, B. G. Lamme. Methods of obtaining regenerative and braking action with a single-phase commutator traction motor of the series type. The field winding is so highly inductive that the field flux produced lags nearly 90° behind the impressed E.M.F.; consequently the E.M.F. generated by the armature is considerably out of phase with the line E.M.F. In order that this generated E.M.F. may be in phase with the line E.M.F., the field winding must be separately excited by means of a phase changing device as an induction motor or motor-generator. When it is required that the motor should generate, the armature is connected direct to the main transformer, and the field winding is supplied with an E.M.F. of suitable phase and value from the generating winding of the phase-changing device. The field winding can be connected permanently in series with the armature, the generating winding of the phase-changing device being connected across the field winding as a shunt. Other modifications are described in the specification. Four claims, seven figures.

5,508A, B. G. Lamme. For the same purpose as the above arrangement (No. 5,506A), the field winding of a series commutator motor is excited separately from the armature of an auxiliary commutator machine, the field winding of the auxiliary machine being excited from the line supply. As the E.M.F. generated by the auxiliary machine is approximately 90° out of phase with the line E.M.F., the E.M.F. generated by the main motor will be nearly in phase with the line E.M.F. It has been found that power can be returned to the line in this way with a power-factor of 98 per cent. If several motors are on the same car, one of these can be used as the auxiliary machine supplying current to the field windings of the other motors. Three claims, four figures.

8,284, M. C. Thiellet and M. J. Denard. Compositions for the active materials in the plates of accumulators, harder and less liable to disintegration than those in use. The active material for the negative plate is composed of 80 per cent. lead oxide, 10 per cent. minium, and 10 per cent. sulphate of magnesium, with gelatinous bichromated silicate added to form a paste. The material for the positive plate consists of 80 per cent. peroxide of lead, 10 per cent. lead oxide, 5 per cent. pumice stone, and 5 per cent. sulphate of magnesium, with gelatinous bichromated silicate as before. The preparation of this last is described in the specification. One claim, no figures.

13,354, F. P. Driver. A cement for attaching the filaments to the leading-in wires of incandescent lamps, and consisting of a finely divided refractory metal as tungsten or molybdenum made into a paste with a solution of silicate of potassium or sodium. The filaments are cemented on with this composition, and the joint is then heated, either by passing current through it or by means of an electric arc, in an atmosphere of hydrogen. A good metallic contact free from carbon is obtained, and only a very small amount of troublesome gases is given off during exhaustion One claim, no figures.

20,600, E. Heitmann and F. W. Young. Wedges of cast iron or high-resistance steel for closing magnetically the slots of alternators or induction motors. The wedge is thin along the centre in order to reduce the flux round the slot, and the thick sides, nearest the teeth, are slotted transversely in order to reduce the eddy current loss. Five claims, four figures.

22,833, F. Conrad. An armature winding for alternating-current commutator motors of the type in which the number of field poles is altered when changing over from commutator motor working to induction motor working. The winding is provided with cross connections which act as equalising connections in the former case and as short-circuiting connections in the latter case. These cross connections divide the winding into groups, each of which contains coils connected to two or more commutator segments. The cross-connections permit of a single pair of brushes being used for a multipolar machine, and by this means only one coil is directly short-circuited at a time, the coils in parallel with the directly short-circuited coil have other coils in series with them, in which opposing E.M.F.'s are induced. Resistance conductors between winding and commutator segments are rendered unnecessary. Two claims, four figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of the more important of these patents will appear in our next issue.

1906 Patents

19,378A, Bounevialle. Electrical signalling apparatus.
29,647, Merk. Automatic telephone exchange systems.

1907 Patents

2,383, Mitchell. Electric contact devices.
2,587, Howard. Arc lamps.
2,588, Albrecht. Transmission gear for motor vehicles.
4,709, Fessenden. Signalling by electromagnetic waves.
4,710, Fessenden. Transmission of energy by electromagnetic waves.
4,910, Dassomville. Electrolytic bleaching.
5,133, Leitner. Compound wound electric motors.
5,187, Carbonnelle. Transmission of illustrations.
5,300, Garrod. Joint arrangements of the side slot conduit system of electric traction
5,402, Suchostawer. Surface contact traction system.
5,564. Mershon. Control of alternating-current motors.
5,671, British Thomson-Houston Co. and Hopps. Control of electrically propelled vehicles.
5,733, Golby (*Soc. Alsacienne de Constructions Mecaniques*). Polyphase commutator motor.
5,741, British Thomson-Houston Co. (*General Electric Co.*). Commutating poles.
5,749, Griffiths and Bedell. Cable for the stud-contact traction system.
5,925, Triquet. Primary cell.
6,006, Bowden, Robinson, and Jacks. Prepayment mechanism for electric meters.
6,135, British Thomson-Houston Co. (*General Electric Co.*). Signalling systems for railways.
6,992, Notarianni. Electric railway signalling.
8,881. Parsons. Inter-communication telephone systems.
9,029, Borgnet. Electrolytic apparatus.
10,152, Siemens & Halske Akt.-Ges. Conversation counters.
11,582, Fleming. Wireless telegraphy.
11,814, Scott. Electric circuit-breakers.
14,203, British Thomson-Houston Co. (*General Electric Co.*). Dynamo-electric machines.
15,441, Conrad. Voltage regulation.
15,773, Powles and Moore. Double sounders.
16,346, Turbayne. Systems of distribution.
17,539, Gilstrap. Elevated electric railways.
17,832, Sawyer. Trolley wheels for electric traction.
18,242, Schöppe. Electric fire-alarm system.
18,243, Szubert. Arc lamps.
20,128, Eisenstein. Multiple wireless telegraphy.
21,407, Garratt. Brush holder.
21,982, Drewet. Trolly heads or collectors.
22,832. Lamme. Armatures for electric motors.
23,681, Steinthal and Jessop. Contact plugs.
23,877, Barth and Lökken. Electromagnetic sound producers.
23,894, Moscicki and De Modzelewski. Condenser.
24,587, Keller. Flexible electrical connectors.
24,697, Viel. Electric furnace.
24,770, Wolhaupter. Insulated rail joints.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

4,181, Lassen. Electrically propelled motor car.
4,274, O'Keenan. Compensating for friction in meters.
4,372, Felten & Guilleaume Lahmeyerwerke Akt.-Ges. Pressure regulation.

THE PROPOSED HOME OFFICE REGULATIONS

(Special Report. Strictly Copyright)

SINCE the adjournment of the inquiry before Mr. James Swinburne, F.R.S., on Wednesday, the Committee of Objectors, in conference with the advisers to the Home Office, have completed consideration of the whole of the Regulations. In our last issue we gave the agreed amended draft up to Regulation 20, with the exception of Regulations 17 and 18, the discussion of which had been postponed. These two Regulations have now been agreed upon, and, together with the remaining thirteen Regulations, are given below. Other modifications have been introduced into the definitions and exemptions, and these are also given below.

In the draft regulations as they now stand, the definition of "Cable" has been omitted, and consequently in several of the regulations the word has either been omitted or changed to *conductor*. The definition of circuit now reads as follows :—

"Circuit" means an electrical circuit forming *a system or* branch of a system (the words in italics have been added).

Some slight alterations have been made in the exemptions.

Exemption 4, as given on p. 381 of our issue of March 12th, has been added to, and now reads as follows :—

Nothing in these Regulations shall apply on the premises of an occupier, being a consumer of an authorised electricity supply undertaking, to any service lines or apparatus on the supply side of the occupier's terminals, belonging to and under the control of the *suppliers, provided such suppliers are subject to Board of Trade Regulations in respect of such supply.*

The next exemption takes the slightly shortened form below :—

If the occupier can show with regard to any requirement of these Regulations that the special conditions in his premises are such as to adequately prevent danger, that requirement shall be deemed to be satisfied.

An entirely new exemption has been added, reading :—

Nothing in these Regulations shall apply to any process or apparatus used exclusively for electro-chemical or electro-thermal or testing or research purposes; provided such process be so worked and such apparatus so constructed and protected and such special precautions taken as may be necessary to prevent danger.

Of the Regulations themselves, apart from the substitution of the word conductors for cables in Regulation 2 and an unimportant verbal alteration in Regulation 9, there is no alteration until Regulation 17, the consideration of which was postponed until after the others. We give this regulation in its amended form below :—

17. At the working platform of every switchboard and in every switchboard passage way, if there be bare conductors exposed or arranged to be exposed when live so that they may be touched, there shall be a clear and unobstructed passage of ample width and height with a firm and even floor. Adequate means of access, free from danger, shall be provided for every switchboard passage way.

The following provisions shall apply to all such switchboard working platforms and passage ways constructed after the 1st January, 1909, unless the bare conductors, whether overhead or at the sides of the passage way, are otherwise adequately protected against danger by divisions or screens or other suitable means :—

(*a*) Those constructed for low pressure and medium pressure switchboards shall have a clear height of not less than 7 ft., and a clear width measured from bare conductor of not less than 3 ft.

(*b*) Those constructed for high pressure and extra high pressure switchboards other than operating discs or panels working solely at low pressure shall have a clear height of not less than 8 ft. and a clear width measured from bare conductor of not less than 3 ft. 6 in.

(*c*) Bare conductors shall not be exposed on both sides of the switchboard passage way unless either the clear width of the passage is in the case of low pressure and medium pressure not less than 4 ft. 6 in., and in the case of high pressure and extra high pressure not less than 8 ft., in each case measured between bare conductors, or the conductors on one side are so guarded that they cannot be accidentally touched.

It will be seen that important alterations have been made. Sub-sections (*a*) (*b*) and (*c*) are entirely new, and although they embody a portion of the restrictions previously contained in the first part of the Regulation, the effect of the changes is to reduce the permissible width of a passage way in the case of high-tension apparatus from 4 ft. to 3 ft. 6 in., and to reduce the minimum width allowable in the cases with bare conductors on both sides of the passage from double that required in other cases to the figures given above.

In Regulation 18, the words shown below in italics have been added :—

(*a*) Every *high pressure and extra high pressure switchboard* conductor within reach from the working platform or in any switchboard passage way shall be so placed or protected as to prevent danger.

The remaining Regulations, the consideration of which by the committee was subsequent to our last report, are given in full in their amended form below :—

Regulation 21. Where necessary to prevent danger adequate precautions shall be taken either by earthing or by other suitable means to prevent any metal other than the conductors from becoming electrically charged.

The only alteration is a rearrangement of the wording.

Regulation 22. Adequate precautions shall be taken to prevent any conductor or apparatus from being accidentally or inadvertently electrically charged when persons are working thereon.

Regulation 23. Where necessary to prevent danger, insulating stands or screens shall be provided and kept permanently in position and shall be maintained in sound condition.

These two regulations are unchanged.

Regulation 24. Portable insulating stands, screens, boots, gloves, *or other suitable means* shall be provided and used when necessary to prevent danger, and shall be periodically examined by an authorised person.

The words in italics have been added.

Regulation 25. Adequate working space and means of access, free from danger, shall be provided for all apparatus that has to be worked or attended to by any person.

Regulation 26. All those parts of premises in which apparatus is placed shall be adequately lighted to prevent danger.

Regulation 27. All conductors and apparatus exposed to the weather, wet, corrosion, or to inflammable surroundings or explosive atmosphere, or used in any process or for any special purpose other than for lighting or power, shall be so constructed or protected, and such special precautions shall be taken as may be necessary to prevent danger in view of that exposure or use.

These three regulations have not been altered, but the subsequent numbering has been retained to avoid confusion.

Regulation 28 has been deleted.

Regulation 29. No person except an authorised person, or a person acting under his immediate supervision, shall undertake any work where technical knowledge or experience is required in order to avoid danger.

This remains as before.

Where a contractor is employed, and the danger to be avoided is under his control, the contractor shall appoint the authorised person, but if the danger to be avoided is under the control of the occupier, the occupier shall appoint the authorised person.

The latter clause was suggested by the Institution of Electrical Engineers.

Regulation 30 is left to be dealt with by the Commissioner.

Regulation 31. Every sub-station shall be substantially constructed, and shall be so arranged that no person other than an authorised person can obtain access thereto otherwise than by the proper entrance, or can interfere with the apparatus or conductors therein from outside, and shall be provided with efficient means of ventilation and be kept dry. (This is agreed to subject to Mr. Sparks' clients desiring to raise any further point in their own interest.)

It will be noticed that the words "and substantially constructed of fire-resisting material" have been omitted.

Regulation 32. Every underground sub-station shall be under the control of an authorised person, and none but an authorised person or a person acting under his immediate supervision shall enter any part thereof where there may be danger.

No alteration has been made here.

Regulation 33. Every underground sub-station not otherwise easily and safely accessible shall be provided with adequate means of access by a door or trap-door, with a staircase or ladder securely fixed and so placed that no live part of any switchboard or any bare conductor shall be within reach of a person thereon : Provided however that the means of access shall be by a doorway and staircase : (*a*) if any person is regularly employed therein, other than for inspection and cleaning; or (*b*) in any such sub-station not of ample dimensions, either if there is moving machinery therein, other than ventilating fans, or if there is extra high pressure therein.

The only alteration is verbal.

Regulation 34. *Adequate periodical inspections shall be made by an authorised person to ensure that these Regulations are fully complied with.*

This Regulation has been added.

TUESDAY, MARCH 24TH.—EIGHTH DAY.

At the commencement of the proceedings Mr. GRAY outlined the agreement that had been come to on Regulations 21 to 33, which are given above.

With regard to a suggestion by Mr. Vesey Knox that docks should be included in Exemption 2, he stated that he was willing to add the words, "or for docks constructed under

Digitized by Google

statutory powers" after the word "traction" in this exemption.

With regard to Exemption 4, he submitted the following draft modification, which had been prepared by Mr. Ram:—

"The Secretary of State may exempt from these regulations any service lines and apparatus on the premises of an occupier being a consumer supplied by an electricity undertaking on the supply side of the consumer's terminals, provided that such suppliers are subject to Board of Trade regulations in respect of such supply.

Mr. Vesey Knox, K.C., pointed out, with regard to Regulation 4, that he found a good many people were troubled about the word "inadvertently." With most switches it was possible for careless workmen to leave them in partial contact, and it seemed to him that instead of the word "inadvertently," which it was perhaps rather difficult to understand, the words "with ordinary care" might better express what they meant.

Mr. Gray then stated that the committee of objectors and the advisers of the Home Office, had come practically to an agreement upon the whole regulations, although the amended draft did not bind anyone definitely, and he would like an indication as to what now would be the attitude of the objectors.

Lord Robert Cecil, K.C., M.P., on behalf of the London electric lighting companies, outlined his course of action, which he dealt with more fully in his speech later on in the day. Most of the other objectors stated their intention of adopting Lord Robert Cecil's argument to a large extent.

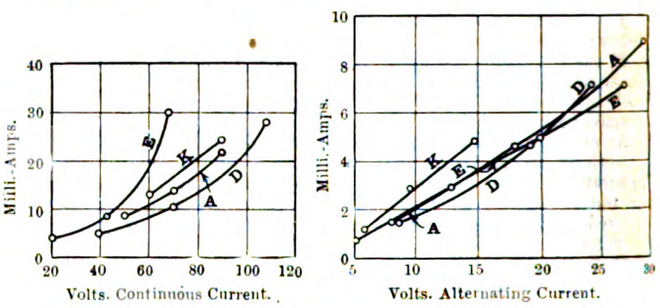
Mr. W. B. Woodhouse, on behalf of the Yorkshire Power Co., and other objectors asked for an explanation with regard to one or two of the altered clauses. The wording in Regulation 11, for instance, was not quite clear. Was it intended that a bank of transformers, if controlled by one switch, would satisfy that regulation?

Mr. James Swinburne stated that he did not quite see this point, as if the whole bank of transformers could be turned off this would meet the case. There was no need to have arrangements for turning off each individual transformer.

Mr. Woodhouse then asked if "line shafting" was included in Regulation 12 under the word "machinery." If this were so, he thought they would be as badly off as ever. For instance, with line shafting running in three rooms, if that line shafting was to be treated as machinery, then in each of the rooms there must be means for stopping the motor.

Mr. Gray said he was afraid the word "machinery" did include shafting, and, in his opinion, if the shafting was dangerous it ought to be included.

Mr. Woodhouse next referred to Regulation 15, which referred to an area being set apart for the construction of a switchboard. Was it to be taken that a generating station was an "area" set apart for a switchboard, and that no special fencing of the switchboard would be required?



Mr. Gray said that no special fencing would be required.

Mr. Woodhouse, on Regulation 20, mentioned a small point, and suggested that the words "at a lower pressure" should be struck out so as to make the regulation include transforming up as well as transforming down.

Mr. Gray agreed to this.

Mr. Woodhouse, referring to underground sub-stations, dealt with in Regulation 33, mentioned the existence of a Board of Trade regulation on this point for high pressure and extra high pressures. It was occasionally convenient to use the basement of a factory for a transforming chamber, and if these were to be considered "underground sub-stations," then they would come up against the Board of Trade regulations.

Mr. W. H. Patchell was then called on behalf of the Home Office, and said he had made two sets of experiments during the past three weeks upon the question of voltages, the results of which are set out in the diagram. He said he had, at one time, held the opinion that the pressures of 130 volts for continuous current and 65 volts for alternating current were too low, but having made the experiments in question, he had rather changed his mind. In the first set of experiments there were three experimenters, and they first investigated the relative effect of continuous and alternating current. They first tried 72 volts continuous current with two bare copper contacts ¾ in. in diameter, and they found it quite comfortable. It was later found that 50 volts alternating current was about the equivalent of 100 volts continuous current; 16 volts alternating current could hardly be felt, and the same remarks applied to 50 volts continuous current. Then at 50 volts alternating current they gripped the copper contacts as hard as they could, but they could all leave go easily. There was no sort of contraction of the muscles whatever. At 65 volts alternating current, however, he could not grip hard, because he felt a distinct contraction of the muscles. At 130 volts continuous the effect was just about the same. They then tried, having in view the fact that possibly the quantity of current that went through the body was an important factor, how much current they could take comfortably. One experimenter took 2·8 milliamperes, another 7, whilst he himself could take 10 milliamperes without discomfort. With continuous current one experimenter took 12-13 milliamperes, another 25, whilst he took 27 milliamperes. A very important point in these experiments was the state of the skin. Following these experiments, he had others made for him by three other people. In this case the copper bars were one inch in diameter, and experiments were made on both continuous and alternating current. Dealing first with continuous current, one experimenter with 20·2 volts took 4 milliamperes and hardly felt it. At 42 volts he took 8·1 milliamperes, and distinctly felt it. At 68·5 volts and 30 milliamperes there was a painful burning of the hands, and a blister on one of the fingers. The next experimenter at 40 volts took 5 milliamperes, and was slightly shaken; at 70 volts and 10 milliamperes his muscles were contracted, and at 100 volts and 20·3 milliamperes he felt his hands burn. The third experimenter at 50 volts and 8·6 milliamperes felt his right hand slightly warm. The same experimenter at 70 volts and 13·8 milliamperes felt a pricking in the finger points, and at 90 volts and 42 milliamperes there were sharp pains. With a workman 60 volts and 12·9 milliamperes were hardly felt at all, whilst at 90 volts and 24·2 milliamperes there was a distinct pricking in the right thumb. The alternating-current experiments were taken in the same order. The first experimenter at 5·2 volts and 0·2 milliamperes could hardly feel it. At 12·9 volts and 2·9 milliamperes it was distinctly felt; at 18 volts and 5·2 milliamperes it was only with difficulty that he could move his hands, and at 27·4 volts and at 7·1 milliamperes he could not keep his hands on the bars, the effect was so painful. The next experimenter took 8·6 volts and 1·4 milliamperes, and then 19·3 volts and 4·7 milliamperes. With the latter the wrists and muscles were badly contracted. At 24 volts and 7·2 milliamperes the arm muscles were contracted. The third experimenter at first took 10 volts and 1·5 milliamperes, and then 19·9 volts and 4·8 milliamperes. With the latter he had what were described as convulsive pains; 29·6 volts and 8·7 milliamperes were quite as much as this man could stand. The workman then tried 9·7 volts and 2·8 milliamperes, and found it very disagreeable, whilst with 14·7 volts and 4·8 milliamperes his wrists were contracted.

Curves showing Variable Susceptibility to Electric Shock of Different Persons, illustrating Mr. Patchell's Evidence.

Mr. Gray: Having regard to your own knowledge of these matters and to the experiments you have made, what is your view with regard to 65 volts alternating current and 130 volts continuous current as regards risk of accident to workmen by accidentally touching one of these voltages?—I think the risk is greater through carelessness, and unless proper precautions are taken, serious accidents are likely to occur.

Lord Robert Cecil: My contention is that these laboratory experiments are not of much use for the purposes of this inquiry. As a matter of fact the pressure at which you had to leave go in your experiment is half what is given in the regulations.

Mr. Patchell said that they must look at these things from the point of view of a lower pressure than that which had proved to be dangerous in the past.

Lord Robert Cecil, in a further course of questions, pointed out that in Mr. Ram's report as Electrical Inspector of Factories for 1906, in a table of fatal accidents, there was only one accident which had occurred upon a system where the voltage was less than 250, which was at Derby, upon a 200-volt alternating current system. In the continuous current there was nothing below 500 volts, and these were all electric railway accidents.

Mr. Patchell, in further cross-examination, said that he did not know of any commercial alternating current system as low as 65 volts, but there were continuous current systems at under 130 volts, and he agreed that whereas these systems would be exempt from the regulations, no alternating current systems would be, and in London, where there was competition between companies supplying on the different systems, the 110 volts continuous current supply would receive preferential treatment.

In answer to Mr. Vesey Knox, Mr. Patchell stated that the periodicity of the alternating current experiments was 88 volts in the first set, and 50 volts in the second. He admitted that it would be difficult to reproduce in a factory the condition of perfect contact obtained in the experiments, but he knew of many cases of bad contacts which would approximate to the experi-

Digitized by Google

mental conditions. Further questions by Mr. Vesey Knox directed towards showing the unreliability of the experiments were to the effect that if the results indicated were obtained with 30 volts alternating current and 60 volts continuous current, there was every possibility, as the experiments were continued up with the higher pressures, that the degree of danger with direct current might overtake that of alternating current, because the resistance of the body would fall considerably as indicated by Mr. Patchell.

Mr. PATCHELL replied that it was very difficult to argue which way the tests would go if the experiments were extended. About five seconds was the longest time during which the experimenter could stand the current.

Mr. COZENS HARDY asked whether in the first exemption Mr. Patchell would agree to raise the voltage of the exemptions as regards authorised persons only. Mr. Patchell replied that he thought this would leave an enormous number of dangerous points in existence in various installations, although they might not necessarily be dangerous *qua* shock. This closed the evidence of the Home Office.

Mr. C. P. SPARKS was then called on behalf of the Electric Lighting Companies of London, on the question of voltage. As the exemptions stood at present, he suggested that there should be no limit of voltage specified at all, as there was no commercial alternating current systems under 65 volts, and consequently all alternating current system came within the regulations. Up to 1895 the Board of Trade set the limit of voltage for the application of their regulations at 150 volts alternating, and 300 volts continuous current, but subsequently a committee, consisting of Lord Kelvin, Sir William Preece, and Major Cardew, reported in favour of having the same limit of pressure for both systems, and this was fixed at 250 volts. He could not call to mind any accident upon his undertakings at a less voltage than 250. With regard to the regulation stipulating that rules for resuscitating persons suffering from electric shock should be exhibited in all factories, he thought nothing would prejudice the use of electricity in favour of gas or other forms of power more than this. With reference to sub-stations, the County of London Electric Supply Co. now had 161 transformer boxes placed under the highways, and they were inspected twice daily by their own staff. There was a space of 3 ft. 3 in. between the side of the panels and the inside of the boxes, and under the present regulations such boxes would be illegal. He asked that Regulations 25 and 31 to 33 should not apply to sub-stations or transformer stations constructed in accordance with plans prescribed or approved by the Board of Trade, or to any extension of such systems upon similar construction.

Mr. SPARKS, in answer to various questions, expressed the opinion that personally he thought the transformer boxes, to which he had referred, were quite safe, but they did not comply with the regulations; he therefore wished to have them definitely exempted.

Mr. GRAY indicated that he would be prepared to agree to a letter from the Secretary of State exempting such sub-stations or extensions of them.

Lord ROBERT CECIL replied that this would not hold good in a case of prosecution, and there must be a specific exemption in the regulations.

In answer to further questions by Mr. GRAY, Mr. Sparks stated that he thought the regulations in their modified form were preferable to what they were originally, and he did not think they introduced bad workmanship; in fact, he thought they would maintain a good standard. He did not regard Mr. Patchell's experiments as indicating a commercial danger.

Lord ROBERT CECIL then addressed the Commissioner on behalf of the London Electric Lighting Companies and others, and dealt first of all with the question of voltages. He said he desired to press upon the Commissioner the unfairness introduced by the first exemption, for it put upon all alternating current systems the obligation to comply with the regulations whilst continuous current systems under 250 volts were exempt. He therefore pressed for the alteration of the limit of pressure to 250 volts in both cases. He urged that the difference in danger between the two forms of current was not sufficiently well established to justify a distinction such as was proposed. Presumably the Home Office had some reason for fixing 150, but no real explanation had been given. With regard to regulation 30, dealing with instructions for resuscitating persons suffering from electric shock, his clients felt strongly that under no circumstances ought this to be put upon them, and even if the Commissioner did not exempt supplies below 250 volts they hoped he would exempt them from Regulation 30. Reverting to the question of supply in London at 100 volts direct current, which would be subject to the regulations in competition with alternating current supply which will come under the regulations, Lord Robert Cecil pointed out that the St. James' Co. supplied about half their consumer at 107 volts direct current, and all the West End district of the Charing Cross Co. were supplied at 100 volts, and in many cases the two systems were in competition. He was not aware that any serious objection had been raised to this course by the Home Office, except the departmental one that it was not desirable, and also on the score of expense, but in his view the cost of arbitration would be no more than that attaching to proceedings in a court of summary jurisdiction, and subsequently in the court of petty sessions, while the result would certainly be much more satisfactory.

Mr. SWINBURNE: Is there no set of regulations except the Coal Mines Regulation in which there is an appeal?

Mr. GRAY: I am told there is no such case. Many of the sets of regulations have no appeal whatever.

Lord ROBERT CECIL, continuing, said that under the Factory Acts even with regard to fire it was not thought necessary to enforce the regulations upon existing buildings, and before any structural alterations were required a factory inspector had to say definitely, "This is dangerous," and even then the occupier had an appeal. There was a large number of precedents in existing work which were exempted, and he asked for Regulation 55 of the Coal Mines Regulations with a few drafting alterations which were necessary.

In the course of further remarks, Lord ROBERT CECIL asked that the new Regulation 34 should be struck out altogether.

Mr. GRAY interposed that he had a grievance in this connection, as he was given to understand at the conference that the objectors agreed with this. However, he was willing to strike it out.

Mr. VESEY KNOX, on behalf of the Newcastle and other power companies, and the Mersey Docks and Harbour Board, first referred to a point raised by the latter, on the question of responsibility for the "authorised person," as defined in these regulations. He pointed out that under the Factory Acts the "occupier" of a dock was defined as the owner, but the owner of the dock was also joint occupier of a ship, and was liable to prosecution. Now, under these regulations, the "authorised person" was introduced, and apparently the dock company was also to be liable in respect of the electrical contractor's men on board a ship, if they turned out to be not competent. With regard to exemption from prosecution, he suggested the following provision:—"No person shall be deemed to have acted in contravention of or to have failed to comply with these regulations unless the Electrical Inspector of the Home Office shall have certified that there is, in his opinion, good ground for proceeding against such person." In other words, he asked for the *fiat* of the Chief Electrical Inspector.

The inquiry was continued yesterday, and will be concluded this morning.

LOCAL NOTES

ACTON: *Electricity Charges.*—The District Council is considering the views of a deputation of local traders protesting against any increase in the charges for electricity. The Electricity Committee had resolved upon the substitution of the charges first in force in the district for present rates, it being proposed to supply current for lighting at 4d. per unit to churches and chapels, and 5d. to all other consumers, and for power at 2d. per unit. The deputation complained that it was unfair to revert to the old scale, after only six months' trial of the new charges. The present 4d. rate was higher than the Hammersmith rate. Two members of the deputation expressed themselves as being in favour of traders having private installations if charges were increased. Mr. John Beauchamp remarking that he knew a firm who would give a written guarantee that he could generate his electricity for a penny. The chairman of the Council promised that the views of the deputation should be taken into consideration.

BIRMINGHAM: *Chairman of Tramways Committee.*—Alderman Beale, the present Chairman of the Tramways Committee, has been offered the Chairmanship of the Water Committee. If this offer is accepted it is anticipated that Councillor Harrison Barrow will be elected Chairman of the Tramways Committee.

On Monday, the 23rd inst., the Lord Mayor opened an exhibition of arts and industries in the Bingley Hall. Among the exhibits is an interesting display by the Corporation Electric Supply Department, which includes a great variety of electric light fittings, radiators, fans, and motor-driving machines of different types. There is also a considerable section showing machinery in motion.

BRADFORD: *Tramway Employees' Grievances.*—The Tramways Committee has received a reputation in connection with certain dismissals of drivers who have been accused of failing to comply with the regulations in reference to speed of cars. The deputation represented that owing to the slow speed regulations, and the time-table to be maintained, it is impossible to comply with both. The Committee has decided to adjourn the matter in order to obtain fuller information.

BRIGHTON: *Shoreham Harbour and the Electricity Works.*—Mr. J. Christie, the Engineer and Manager of the electricity undertaking, has reported that he has driven in a row of dwarf piles in the harbour alongside the electricity works, and

Digitized by Google

that the sky line has been restored to its original level. In his opinion, everything is now quite safe.

BURY: *New Electricity Works.*—At a largely-attended meeting of manufacturers and others at the Town Hall on Friday it was decided to ask the Mayor or convene a public meeting to discuss the question of the new electricity works which it is proposed to erect at a cost of about £100,000, before the Local Government Board inquiry with regard to the necessary loan is held. The general feeling, although not antagonistic to the proposal, seemed to be that sufficient opportunity had not been given to the ratepayers and others interested to consider the proposed scheme.

COWDENBEATH: *Electric Lighting.*—The Fife Electric Power Co. announce that they are extending their mains to Cowdenbeath, and anticipate giving a supply in the district next year.

DUNFERMLINE: *Electricity Supply.*—The Town Council being unwilling to take the responsibility of deciding as to what course shall be pursued in connection with the proposed electric lighting scheme, has decided to take a plebiscite of the ratepayers in order to ascertain their views: (1) Whether the Corporation shall erect a generating station; (2) whether a supply shall be taken in bulk from the Fife Electric Power Co.; (3) whether the Council's Provisional Order shall be disposed of as recommended by Sir Alexander Kennedy.

EDINBURGH: *Edinburgh Exhibition.*—The proposal to construct an electric tramway from the Murray Fields terminus of the present cable tramway system to the Edinburgh Exhibition, referred to on page 452 of our last issue, has been rejected by the Corporation. Sir Alexander Kennedy, as Consulting Engineer to the Corporation, severely criticised the system on several points of detail at the meeting of the Tramways Committee last week, and also objected to the system on the ground that it had not yet been experimented with upon private land. He did not think the system should be subjected to the strain of heavy traffic such as would be involved at the Exhibition until experiments had been made with it.

GILLINGHAM: *Electricity Deficit.*—The accounts of the electricity undertaking show a deficit of £1,000. At the last meeting of the Council, it was stated that the estimated expenditure during the current year is £2,300, making altogether £3,300 to be provided out of the rates, or a rate of 5d. in the £. The Engineer reports that there are three old 100-frequency transformers now out of service, and the committee recommends that he should apply to stations, where these will be suitable, for offers.

GRAVESEND: *Electricity Finances.*—At the last meeting of the Town Council, a motion by the Chairman of the Electricity Committee that, in view of the criticism to which the electrical undertaking had been subjected, the Town Clerk, the Treasurer, and the Electrical Engineer should prepare a joint report as to the financial position of the undertaking, was adopted.

HALIFAX: *Tramway Returns.*—The Finance Committee reports that there will be a heavy loss on the tramways for the past year, owing to the accident on the Sowerby Bridge route in October. It is suggested that the loss can be met by making use of the surplus for the previous year.

HANLEY: *Tramways.*—The Board of Trade has intimated to the Council that after careful consideration of its objections to the Potteries and North Staffordshire Tramways (Amendment) Provisional Order, they see no sufficient reason to refuse to allow the promoters the benefit of Clause 5, which prevents the Corporation from imposing special conditions as to the manner in which certain street widenings shall be carried out. In connection with this matter, a conference has been convened by the Town Clerk to the Stoke Corporation for the purpose of considering the desirability of petitioning against the Order referred to above. A deputation from Hanley will attend this conference.

Electricity Matters.—It has been decided that the wiring of consumers' premises carried out on the deferred payment system shall be charged against a wiring account into which receipts therefrom shall be paid. Meters, indicators, spare or renewal parts for plant, hand tools, and small testing instruments are in future to be paid for out of revenue, as they are purchased. A stores stock account is to be kept at the electricity works, and a prime cost clerk is to be engaged.

HANWELL: *Condition of Tramway Track.*—The District Council, at its last meeting, considered a letter from the Board of Trade on the subject of the condition of the rails and substructure of the London United Tramways in Hanwell. The letter in question enclosed a copy of a communication, which the Board had received from the company, which expressed the opinion that there were no grounds for the complaints which had been made. The tramway track in Hanwell, the company asserted ,is in good order and condition, both as to rails and paving, no expense having been spared by the company to fully maintain its obligation in this connection. The statements contained in the letter from the Hanwell surveyor concerning the condition of the track were described as being grossly exaggerated. The company's permanent way in Hanwell was in equal condition to that in Ealing at the date of the inspections, to which reference has been made. The surveyor of Hanwell refers to reconstruction work now being carried out by the company in Acton. This track was laid with 80 lb. rails and put into service in 1895. The track in Hanwell was laid with 92½ lb. rails, and put into service in July, 1901. The Acton reconstruction was undertaken because it was considered by the company to be necessary, and was not the result of any pressure whatever." It was agreed to inform the Board of Trade that the company's letter was a gross mis-statement of the facts.

HASLINGDEN: *Electricity Supply.*—The negotiations between the Council and the Rawtenstall Urban District Council with regard to electricity supply have failed, and the Haslingden Council will now erect a separate generating station. Arrangements have been come to, however, with regard to tramway running powers over the lines in the respective districts.

HEBBURN: *Tramways.*—The Urban District Council has been informed by the Gateshead & District Tramways Co. that the company does not see its way clear at the present time to undertake the necessary expenditure for extending their system to Hebburn, but should the Council obtain the necessary powers and construct the lines, the company will be willing to work the extension under a lease.

HESTON AND ISLEWORTH: *Electricity Profits.*—A report has been issued by the Clerk of the Council, giving some particulars of the electricity undertaking. It appears that the loss for the first three years working amounted to 11s. 10d., and a profit of £237 is anticipated for the current year The report calculates that under private management the results would have justified the payment of a 5 per cent. dividend, and the placing of a substantial sum to depreciation account.

HULL: *Telephone Undertaking.*—During the past year, 257 additional instruments have been fixed in connection with the telephone undertaking. The number added during the last three months has been 170, which is a record increase for any quarter since the undertaking was first started.

LEEDS: *Proposed Tramway Extensions.*—The Tramways Committee has promised to consider a proposition by the Farsley Urban District Council that the Leeds Corporation Tramways should be extended from Rodley to Farsley.

LIVERPOOL: *Workmen's Trams.*—Mr. C. W. Mallins, the Traffic Manager, has prepared a report upon workmen's tram fares in Liverpool in consequence of a suggestion that the present facilities should be extended. The report points out that the receipts between 4.30 a.m. and 8 a.m., when the service is chiefly operated for workmen, was less per car mile by 2·28d. than during the other hours of the day, and the comparative loss per annum is £914 over actual working expenses. If the earnings were equal to the remaining portion of the day, a sum of £6,090 per annum would be received, and adding this to the loss of working expenses, there was a total loss on the workmen's traffic of £7,004 per annum. London, Glasgow, and Bradford all report a loss on workmen's fares, and to extend the system in Liverpool to include school children would mean an increase of rolling stock, the cost of which, says Mr. Mallins, would probably turn the small margin of profit on the undertaking into a loss.

LLANDUDNO: *Sunday Trams.*—The shareholders of the Llandudno Tramways Co. have decided to support an application to the Llandudno Council for permission to run the cars on Sundays.

LONDON: *London County Council.*—At the weekly meeting on Tuesday last, Mr. Hayes Fisher, in moving that the report of the auditors on the tramways accounts be received, said that though the report showed conclusively that the tramways had never earned a legitimate penny of profit, he thought that they would be able gradually to write out the losses on the horse tramways, build up a renewal fund, and pay a proper proportion of the establishment charges. The development of tramways in parts of London where they would not pay, and any yielding to improper pressure to reduction in fares, must be guarded against. Mr. McKinnon Wood did not see why the losses on the displaced assets of the horse system should have to be met from the working charges of the undertaking. The Metropolitan Railway had been paying a little, but had not written off its old lines. They (the Council) had followed the practice of other municipal corporations (for instance, Liverpool) who had tramways, and he denied that they were being judged on commercial lines.

London County Council: Tramways.—In a report by the Highways Committee, it is stated that among tramway works to be undertaken during 1908-9, is now included the reconstruction of the lines transferred to the Council from the South London Tramways Co., namely, (1) from Nine Elms via Wandsworth Road, Lavender Hill, and St. John's Hill, to East Hill Wandsworth, and (2) from Lavender Hill, via Queen's Road, Battersea, to Chelsea Bridge. An estimate of £7,000 in respect of the removal, lowering, or diversion and mains, pipes, wires, &c., along the first-named route has already been sanctioned, as also have estimates for the reconstruction of the lines for the underground conduit system. It is now proposed that the tramways in Queen's Road should also be constructed for the same system, and the estimate for this route, which is about 1¼ miles long, double track, is as follows:—track work, &c., including special work, £7,100; for rails, £46,500; cables, &c., £1,223; cable ducts, &c., £1,040; rolling stock, £4,250; making a total of £53,013. Owing to the low headway of certain railway bridges which cross Queen's Road, it will only be practicable to run single deck cars on this route.

Digitized by Google

Battersea.—The Borough Council, after having taken the advice of counsel, have decided to defend an action brought by Messrs. Mather and Platt, Ltd., for £800, the price of a spare armature, and to make a counterclaim. The dispute arises out of the firm's contract for the supply of steam generating plant.

Hackney.—On January 23rd, the Borough Council adopted a scheme drawn up by the Electrical Engineer, for a hire-purchase installation system. A joint report of the Town Clerk, the Borough Electrical Engineer, and the Borough Accountant was circulated this week in regard to the financial arrangements for the scheme. The Council have power to borrow for this work, but in the opinion of the joint authors of the report it will be better to defer as long as possible the taking up of short loans. They therefore suggest that for the present this branch of the undertaking be financed by the uninvested surpluses of the electricity undertaking.

Hampstead: London Electric Power Bills.—The General Purposes Committee report having instructed the Town Clerk to communicate with the member of Parliament for the Borough, with a view to his opposing the motion to refer the London Electric Supply Bill and the London and District Electricity Supply Bill to a joint committee of the House of Lords and the House of Commons, when the same comes before the House of Commons, as the Committee are of opinion that the opposition of the borough councils to the two measures would be more likely to receive a sympathetic hearing from a Committee of the House of Commons than from a joint committee as proposed.

Shoreditch: Tramway Dangers.—The Borough Council has decided to call the attention of the London County Council to the possibility of danger arising from the congestion of tramway traffic in Kingsland Road. It is proposed to ask the County Council to receive a deputation on the question of widening the road in question.

Stoke Newington.—On the 17th inst., the Borough Council considered resolutions passed at an informal conference of representatives of Metropolitan Borough Councils who are electric lighting undertakers, to the effect that steps should be taken to formulate a scheme for the development of the electricity supply of London by a combination of existing undertakings. It was resolved to reply that in the opinion of Stoke Newington Council it was undesirable that a bulk supply should be provided at the risk of the rates, and that the promotion of any such scheme should be left to private enterprise subject to proper provision being made for purchase by the Local Authority at a reasonable price.

MONMOUTH: *The* £10,000 *Loan.*—Having borrowed £10,000 from the local bank on the security of a local nobleman for the electric lighting works, and the Local Government Board having objected to the rates being used for payment of the interest on this sum, the Corporation has applied for an extension of their borrowing powers to the amount in question as a way out of the difficulty. Mr. J. F. Willis, of the Local Government Board, held an inquiry into the matter last week, when it was stated that the total indebtedness to the bank is £10,533, but there are a few assets available, which will reduce this sum to about £9,000.

OXFORD: *Tramway Position.*—With reference to the arrangements come to between the Oxford Tramways Co. and the National Electric Construction Co., mentioned in our last issue, it appears that the shareholders of the existing company will get a return of 72 per cent. of their capital, 60 per cent. of which will be paid in cash, or 4½ per cent. mortgage debentures, and the remaining 12 per cent. in cash or ordinary shares.

QUEENBOROUGH: *Electric Lighting.*—The Sheerness & District Electric Power & Traction Co. are to be asked to revise their charge for electricity. In event of a refusal, the Council threatens to consider the advisability of using another form of power in connection with the water undertaking.

RAWMARSH: *Dolter Surface Contact System.*—At the last meeting of the Urban District Council, the Town Clerk reported a correspondence with the Mexborough & Swinton Tramways Co., with reference to the many complaints that had been made as to the danger arising from live studs on the tramway system. As a result of negotiations between the Mexborough, Swinton & Rawmarsh Councils, a conference has been arranged between their representatives and the managers of the tramway company, at which certain suggestions made by the latter will be considered.

ROCHDALE: *Tramway Assessment.*—The Tramways Committee has lodged an appeal against the assessment of the tramways, and a deputation has been appointed to wait upon the Assessment Committee with a view to a settlement.

ST. ANNE'S-ON-SEA: *Charges for Electric Lighting.*—The local Tradesmen's Association is approaching the Urban District Council for a reduction in the charge for electricity to private consumers. The present rate is 5½d. per unit.

SANDOWN (I.O.W.): *Electric Lighting.*—A meeting of the ratepayers was recently convened for the purpose of considering whether the public electric lighting should be continued or whether there should be a reversion to gas lighting. A resolution to continue the electric lighting was carried by 155 votes to 57. Mr. A. E. Mayes, Chief Electrical Engineer to the Isle of Wight Electric Light and Power Co., was present, and a somewhat spirited discussion took place between him and the representative of the local gas company.

SOUTHAMPTON: *Tramway Receipts.*—The estimate for the working expenses upon the tramway undertaking last year were £35,249, but the actual expenses were £35,517. The actual income, on the other hand, was £54,365, an increase of £3,289.

WALTON-LE-DALE: *Electric Lighting Order.*—A communication having been received from the Board of Trade with reference to the Electric Lighting Provisional Order, granted to the Council in 1904, the Clerk to the Council has been instructed to inform the Board that no steps have been taken to put this into force, and asking for an extension of time.

WEST HAM: *Tramway Matters.*—The Electric Lighting and Tramways Committee has adopted the recommendation of the Tramways Manager (Mr. H. E. Blain) that the extension of the Barking Road tramway to the Iron Bridge, Canning Town, the estimated cost of which, after allowing credit for the old materials, is approximately £2,600, be now proceeded with. The Tramways Manager has been informed by the Chief Officer of the London County Council tramways that the L.C.C. has not arrived at any decision with regard to extending their present terminus at Poplar to the county boundary. A communication is to be addressed to the L.C.C. inquiring whether, pending the latter authority dealing with their own extension in the East India Dock Road, they would be willing to construct their permanent way from the boundary with West Ham westwards to the foot of the Bridge approach (the portion in question not involving any widening), and, subject to the Poplar Council not objecting, allow the line to be temporarily equipped on the overhead trolley system, and run by West Ham upon terms to be agreed. The Electric Lighting and Tramways Committee have decided that the practice of allocating the anticipated surplus on the Tramways Revenue account to the relief of the rates be discontinued, and that the disposal of such surplus be left over until the amount is ascertained at the close of each year.

WOOD GREEN: *Electric Lighting.*—The North Metropolitan Electric Power Supply Co. has made an offer to the Urban District Council for an electric lighting scheme, which is now under consideration. The cost of the Council's electric lighting Provisional Order up to date is £1,200.

YARMOUTH: *Tramways Electrical Energy.*—The electricity committee is to be asked to reduce the charge of 1¾d. per unit now made for the supply of energy to the tramways.

TENDERS INVITED AND PROSPECTIVE BUSINESS

AUSTRALIA: *Melbourne.*—Tenders are invited for the supply of 30½ miles of bare hard-drawn copper cables. Particulars from Messrs. Mellwraith, McEacharn & Co., Proprietary, Ltd., agents for the Melbourne City Council, to whom tenders by April 7th.

BOSCASTLE.—A scheme for electric lighting is before the Council. The estimated expenditure is to be only £1,000, and there is a strong feeling that a local company should be formed.

BUXTON.—The Local Government Board has sanctioned a loan of £965 for electric lighting purposes.

DORKING.—A Local Government Board inquiry was held last week into the application of the Council to borrow £1,160 for the electric lighting undertaking.

EDINBURGH.—Tenders are invited for the wiring and fittings for electric supply at the Public Washhouse, Simon Square, Edinburgh. Full particulars from Mr. F. A. Newington, Electricity Supply Station, Dewar Place, and tenders to the Town Clerk by April 1st.

FAREHAM.—The Urban District Council has decided to make an application to the Local Government Board for a loan of £10,000, for the purpose of erecting a new generating station. Messrs. May & Hawes, the consulting engineers, estimate that the cost of carrying out the scheme would be £9,300. The scheme includes two 80 kw. generating sets and one 40 kw. generating set, two 120 b.h.p. Diesel engines, and one 60 b.h.p.

FARNWORTH.—The District Council have decided to enter into an agreement with the Lancashire Electric Power Co. for the supply of current in bulk. Application has been made to the Local Government Board for sanction to borrow £7,000 for the erection of a sub-station.

GLASGOW.—The Tramways Department invite tenders for the following during the year ending May 31st, 1909:—Axles, steel tyres, and steel wheels; fuel for depôts; fuel for Pinkston power station; chilled iron brake blocks, car wheels, &c.; carbon brushes; V.I.R. cables; cartage; cast-iron castings; malleable iron castings; cast-steel castings; granite and whin metal and chips; plumbers' material; indiarubber and asbestos goods; springs; tiebars; water, gas, and steam tubes, &c.; galvanised wires; tool steel. Full particulars from the General Manager, 46 Bath Street, and tenders to the Town Clerk by April 6th.

GILLINGHAM.—A Local Government Board inquiry was held

Digitized by Google

last week into the application by the Council for sanction to borrow £5,000 for the electricity works. There was considerable opposition.

HANLEY.—The application to the Local Government Board for sanction to borrow £18,000, is to be amended so that the amount shall be £21,969, which will cover the estimated capital requirements for the next eighteen months.

HESTON & ISLEWORTH.—The District Council has decided to provide a new feeder cable for the Hounslow district covering a distance of about 2,000 yards at an estimated cost of £1,400.

HOLYWOOD.—A scheme for electric lighting is now under consideration by the Council.

LANCASHIRE.—We understand that the Earl of Ellesmere, Clifton & Kersley Coal Co., Wigan Coal & Iron Co., Ltd., Messrs. Pearson & Knowles Coal & Iron Co., Ltd., and other powerful colliery concerns in south and south-east Lancashire, are about to introduce electrical coal-cutting machines into certain of their collieries.

LANCASHIRE & YORKSHIRE RAILWAY.—Tenders are invited for stores during the twelve months ending April 30th, 1909, including signal and telegraph fittings and telephonic and electric light wires. Full particulars from Mr. Waring, Stores Department, Osborne Street, Manchester, and tenders to the Secretary by March 30th.

LEEK.—Tenders are invited for engine, dynamo, and other foundations and extensions at the generating station buildings. Full particulars from the Surveyor to the Council, fee £2 2s., returnable, and tenders to the Chairman of the Electricity Committee by April 10th.

The Council invite tenders for gas-producer plant and a gas-driven generator. Full particulars from the Electrical Engineer, and tenders to the Chairman of the Electricity Committee by April 11th.

LONDON: *Poplar.*—The Electricity Committee invite tenders for the supply of various switchboards and gear at the electricity works and sub-stations. Particulars from the Electrical Engineer, and tenders to the Town Clerk by April 29th.

PARTICK.—The Town Council invite tenders for the supply of stores for the electricity department during the year ending May 15th, 1909, including cables, meters, service cut-outs, incandescent lamps, arc lamp carbons, &c. Particulars from the Electrical Engineer, to whom tenders by April 4th.

PERTH.—A new cable is to be laid from High Street Port to the top of old High Street, at an estimated cost of about £150.

SALFORD.—Tenders are invited for the following stores during the year ending March 31st, 1909:—Cables, cable accessories, bitumen, cable conduits and pipes, wood troughing and bends, house service cutouts, meters, demand indicators, ammeters (gravity type), circuit breakers and ironclad switches, steel conduits for electrical wiring, electrical fittings and arc lamp globes and motor carbons, glow lamps, arc lamp carbons, electric motors, motor starting resistances, iron castings, brass and gun metal castings, iron and steel bars, plates, &c.; ironmongery, wrought-iron tubes and fittings. Specification, &c., from the Borough Electrical Engineer, Mr. V. A. H. McCowen, Electricity Works, Frederick Street, Pendleton, and tenders to the Town Clerk by March 30th. (See an advertisement.)

SUNDERLAND.—Tenders are invited for the supply of stores in connection with the Tramways Department, including general electrical and car supplies and overhead line material. Particulars from the General Manager, Mr. A. R. Dayson, and tenders to the Town Clerk by April 9th.

WEYMOUTH.—Tenders are invited for (1) a 300-kw. steam turbine and direct-current generator, surface-condensing plant, and (2) extension switchboard panel for same. Full particulars from the Consulting Engineers, Messrs. Kennedy & Jenkin, 17 Victoria Street, London, S.W., and tenders to the Town Clerk by April 18th (see advertisement this week).

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The D.P. Battery Co. have received an order for a battery for telegraph work from the Commonwealth Government of Australia, and a repeat order for additional cells for their battery from the Bunbury Electric Light & Power Co. of Western Australia.

BECKENHAM.—The following tenders have been accepted by the Council:—New battery house, Messrs. W. H. Hyde & Co.; cable trough, Mr. H. R. Mansfield; engine and cylinder, Messrs. C. C. Wakefield & Co.; crank chamber oil, Messrs. Englebert & Co.

BRISTOL DOCKS.—The Docks Committee has placed an order with Johnson & Phillips, Ltd., for complete installation of cable, switchgear, arc lamps, &c., for Avonmouth Docks.

CROYDON.—The Board of Guardians has accepted the tender of Messrs. Pryke & Palmer for the supply of electrical fittings and appliances.

DAVY ARC LAMPS.—Arc Lamps, Ltd., have just received a large order from Messrs. J. Walsh, Ltd., of Sheffield, for 164 of their flame and enclosed arc lamps for lighting their premises. Some eight years ago Messrs. Walsh took alternating current from the Sheffield supply, and 150 Davy arc lamps were installed. The order for 164 lamps, however, is an extension of the lighting in consequence of Messrs. Walsh having decided to instal their own plant, and intend running all the lamps on direct current.

HESTON AND ISLEWORTH.—The District Council have accepted the following tenders for annual supplies for the electricity department:—W. T. Henley's Telegraph Works Co., cables, disconnecting and house-service boxes, and compound. British Insulated & Helsby Cables, house fuse boxes. A. Duckham & Co., engine oil, 1s. 3d. per gallon; cylinder oil, 1s. 8½d. Middleton Bros., castor, 2s. 6d.; resin, 1s. 6d.; rape, 2s. 9d.; sperm, 2s. 9d.; linseed, 2s.; boiled oil, 2s. 1d.; Russian tallow, 5d. per lb. W. Sparrow, paraffin oil, 5½d. per gallon. Geipel & Lange, carbons, £3 7s. 6d. per 1,000. Leeds Contract Co., earthenware troughs (square), £1 6s. 6d. per 100; earthenware troughs (U-shaped), £1 per 100; hard burnt tiles (various sizes), £2 0s. 6d., £3 4s. 6d., £2 5s. 9d., and £1 8s. per 1,000.

HUCKNALL COLLIERY.—An order has been placed with Johnson & Phillips, Ltd., for the supply and erection of three-phase H.T. overhead transmission line.

MANCHESTER.—The Corporation have placed an order with Johnson & Phillips, Ltd., for supply and erection of three-phase transformers for one of their sub-stations.

LONDON: *Battersea.*—The Borough Council has provisionally accepted the tender of Appleby's, Ltd., to carry out works to the crane at the central generating station, so as to enable it to work longitudinally by electricity in lieu of by manual labour as at present, for the sum of £124 10s.

Islington.—The Borough Council has accepted the following tenders in connection with the electricity department:—Boilers for extension at the generating station, Babcock & Wilcox, £10,694; turbo-generator, Willans & Robinson, £8,968. Tenders were also accepted for the supply of coal at prices ranging from 11s. 4d. to 12s. 4d. per ton.

Islington.—The Board of Guardians has accepted the tender of Pryke & Palmer for the annual supply of electrical fittings and sundries.

RAWTENSTALL.—The Corporation have just entered into contracts for a generating station, equipment, part of the main cables for the electric tramways, &c., involving expenditure of £41,051.

YARMOUTH.—The tender of the British Griffin Chilled Iron and Steel Co., Ltd., has been accepted for forty steel tyres at 35s. 6d. each.

COMPANIES' MEETINGS AND REPORTS

BOURNEMOUTH & POOLE ELECTRICITY SUPPLY.—The report for the year ended December 31st, 1907, states that the capital expended during the year amounted to £31,[illegible], making the total expenditure to date £421,198. The net revenue, including £1,634 brought forward from last accounts, amounts to £33,506. Deducting interest on debenture stock, interim dividends, leasehold and special redemption funds and interests, £1,423, and amount carried to reserve for depreciation, repairs, renewals, &c., £5,000, there remains £13,229 for distribution. The directors recommend a final dividend on the ordinary shares for the half-year ended December 31st, 1907, at the rate of 9 per cent. per annum, less income tax, leaving a balance of £938 17s. to be carried forward. The total applications received at December 31st last amounted to the equivalent of 184,841 30-watt lamps (5,545 kw.), being an increase of 25,150 for the year. The total number of Board of Trade units sold for all purposes was 2,860,534, being an increase of 251,057 for the year. The boiler-house at the company's Bourne Valley station has been reconstructed, and additional boilers installed during the year. The business of the Richmond (Surrey) Electric Light & Power Co., Ltd., continues to be satisfactory. A dividend at the rate of 7 per cent. has been declared on the ordinary shares of that company in respect of the year ended December 31st last.

At the annual meeting on Thursday, the report and accounts were adopted. Mr. A. H. Sanderson, the Chairman, who presided, said he thought the result of the year's trading must be regarded as satisfactory, for in spite of the fact that there had been several adverse factors to contend with, there had been a record increase in every department. The expenditure upon capital account during the year—namely, £31,030—had been chiefly on account of mains, buildings, and machinery. The total receipts for the year had increased by £4,652, and so long as their revenue showed this rate of increase they would have nothing to complain of. This increase, however, would have been much better but for the reduction made last year in the

Digitized by Google

rate charged by them for electrical energy supplied to the Bournemouth Municipal Tramways. The equivalent number of 50-watt lamps applied for to December 31st last showed an increase of 26,130, which was a record in the company's history, whilst the units sold increased by 251,037. Since January 1st, 1908, the units sold were 73,916, an increase of 17 per cent. over the corresponding period of last year. The total number of consumers up to date was 4,042, an additional 71 having come on to the mains since January 1st. With a view of keeping their business prominently before the public, considerable improvements had been made at Verulam House, Bournemouth, where the local offices and central transformer and distributing stations were situated. These improvements consisted of elaborate decorations in front of the buildings, providing the means of showing the latest designs and appliances for electric lighting, heating, and cooking.

BRITISH INSULATED & HELSBY CABLES.—At the annual meeting in Liverpool on Monday, Mr. E. K. Muspratt presiding, the report and accounts given in our last issue were adopted. The chairman stated that the orders on the books were very satisfactory, and the conditions obtaining last year, namely, the high price of copper and the tightness of the money market, had now changed.

CITY OF LONDON ELECTRIC LIGHTING.—Mr. J. B. Braithwaite presided at the ordinary general meeting on Wednesday last week, when the report and accounts given in our last issue were adopted. He stated that the capital expenditure during the year had amounted to £39,710, and that the capital account now stood at £291,671. Prior to December 31st, 1906, they had written off, out of revenue, £129,077 from capital account, and seeing that, in addition, they had reserves amounting to over £300,000, he thought the shareholders would agree with him that they were in a very sound position. In addition to paying a dividend of 6 per cent. for 1907, they had applied about 7½ per cent. on their ordinary stock towards strengthening the company's reserves in various ways. The net revenue showed an increase of £12,775, in spite of the fact that the sales to the London County Council tramways in 1906, which amounted to £5,518, did not appear in the accounts for 1907. Further, in spite of the higher cost of coal, their works costs had been reduced by 0·2d. per unit. With regard to the London electric power question, he thought the position was now more satisfactory than it was two or three years ago. He regarded the idea that London was in need of a cheap supply of electricity as fallacious and a myth. Last year they had sold over six million units for power purposes, whilst the County of London Co., in 1907, sold more than half its entire output for power purposes. The Board of Trade return, published in December, showed that no fewer than 66,287,518 units were sold by companies and local authorities in London for power and heating purposes at an average cost of about 1½d. per unit. He maintained there was no demand for a new bulk supply company, and that the existing stations of local authorities and companies were quite capable of improving the electric supply for the metropolis. He was pleased to see the President of the Board of Trade was making an endeavour to treat this as a business problem, and not as one of party politics, and the Board of Trade would render great service to London if it would take the initiative by calling a conference of all parties concerned. At a subsequent special meeting the promotion of the London Electric Supply (Joint Committee) Bill was confirmed.

DIRECT SPANISH TELEGRAPH.—At the annual meeting on Thursday, the report and accounts, given in our last issue, were adopted. Lord Tweeddale, referring to the interruptions to the company's cables, said that the cost of repairing the Bilbao cable—namely, £3,294—had been charged to revenue. He also pointed out that the depreciation of the company's securities, which a short time ago amounted to 16 per cent., had now been reduced to 14 per cent.

LIVERPOOL DISTRICT LIGHTING.—The report for the year ending December 31st, 1907, states that the directors have to record with regret the death of another of their colleagues, Mr. Harold Cunningham, one of the original founders of the company, and, until his last illness, one of the most active workers in promoting the interests of the company. The demand for electricity still shows a satisfactory rate of increase, the units sold for the year amounting to 354,750 units, an increase of 13,325. Owing, however, to the increased cost of fuel and other causes, the resulting profit has not increased *pro rata*. The balance-sheet shows that the value of the "free wired" installations is less than at the corresponding period of last year. This is accounted for by the fact that the directors have decided not to carry out any more of this work, as practically all the houses now being built in the company's area are wired for the electric light during construction. Two of the old installations have been purchased outright, and one written off. The equivalent number of 16 c.p. lamps supplied at December 31st, 1907, was 24,281, an increase of 2,530 during the year. Owing to the continued expansion of the business, it will shortly be necessary to lay down additional boiler plant to provide for the supply next winter, and this matter is having the careful attention of the directors. The gross profits for the year, together with the amount brought forward from 1906, after payment of dividend, leaves a profit available for distribution of £2,315. Of this £20 has been written off the cost of fitting up the offices in Tithebarn Street, and £835 set aside for depreciation, leaving a balance of £1,461, out of which it is proposed to declare a further dividend at the rate of 5 per cent. per annum, less income tax, for the half-year ending December 31st, 1907. The meeting was held yesterday.

LLANDUDNO & COLWYN BAY TRAMWAYS.—Mr. Stephen Sellon presided over the annual general meeting of this company in London on Monday. The accounts show that the expenditure on construction has amounted to £88,218, and closely approximates to the estimates. The number of passengers carried during the year was 174,654, and the average fare per passenger was 2d. About five miles of lines are at work, and the total receipts worked out to 8d. per car mile. The chairman stated that he personally considered the results very satisfactory. The capital issued to date is £99,400. The delay in the construction of the Colwyn Bay section has been due to a difference of opinion with the local authorities as to the material to be used for paving. This matter, however, has been satisfactorily adjusted by the Board of Trade, and the structural work upon the extension has been commenced at both ends. The report and accounts were adopted.

MELTON MOWBRAY ELECTRIC LIGHT.—The report for the year ending December 31st, 1907, states that the lamps connected during the year increased from 16,391 to 17,528. The total number of consumers is now 535. Including the balance of £80 brought forward from last year, the accounts show a net profit of £2,014. After payment of debenture and loan interest, £1,041, writing off the last instalment of £81 in respect of the exhibition expenses, and £75 depreciation and loss on wiring account, there is a balance of £816. The directors recommend that a dividend be declared at the rate of 2 per cent. per annum, which will require £400; that £400 be placed to reserve for renewal of plant, and the balance, £16, carried forward to next year's account. The report and accounts were adopted at the meeting recently.

NEWMARKET ELECTRIC LIGHT.—The report for the year 1907 states that the equivalent of 989 8-c.p. lamps were connected during the year, making the total connections equivalent to 22,713 8-c.p. lamps. Applications for the equivalent of a further 383 lamps have been received during the present year. It has been found necessary to install an additional generating set to the engine-house plant, and the total cost, including buildings, is estimated to be £2,000. In order to meet this liability, it is proposed to raise new capital. The profit on the year's working, together with the sum brought forward from the previous account, amounts to £2,672. Debenture interest absorbs £710, and out of the balance the directors recommend a dividend of 5 per cent., carrying forward £600. The report and accounts were adopted at the annual meeting last week.

NORTH METROPOLITAN ELECTRIC POWER DISTRIBUTION.—At the ordinary general meeting on Tuesday last, Mr. James Devonshire presiding, the report for the year 1907 was adopted. An extraordinary general meeting was held subsequently, in which a resolution to increase the capital to £100,000 by the creation of 5,000 new shares of £10 each was adopted.

NORTH METROPOLITAN ELECTRIC POWER SUPPLY.—The report for the year 1907, a summary of which was given on page 458 of our last week's issue, was adopted at the meeting of the company on Tuesday last. Sir Ernest Spencer, who presided, said that the increased output was due to the opening up of new lines by the Metropolitan Electric Tramways Co., the larger supply to the Willesden and Stoke Newington Councils, and to the increased output by the Distribution Company at Barnet, Hertford, and Enfield. From the commencement of 1908, a bulk supply had been given to the Hendon Electric Supply Co. The increase in expenses was mainly due to the higher price of coal.

SALISBURY ELECTRIC LIGHT & SUPPLY.—The report for the year ended December 31st, 1907, states that the company continues to make progress. During the year the number of consumers has increased from 983 with 31,769 lamps connected to 1,012 with 33,560 lamps connected. The profit on the year's working, including £59 brought forward from last account, amounts to £5,332, and after paying £1,448 18s. interest on debentures and temporary loans, an interim dividend at the rate of 4 per cent for the half year, amounting to £700, and writing off £125 from exhibition account, there remains a balance of £3,059 to be dealt with. The directors recommend that a further dividend at the rate of 7 per cent. for the half year be paid, making, with the interim dividend, 5½ per cent. for the year, and that £1,500 be carried to reserve, leaving £334 to be carried forward to next account. At the meeting recently the report and accounts were adopted.

VICKERS, SONS & MAXIM.—At the annual meeting on Thursday, the report and accounts, given in our last issue, were adopted.

WINCHESTER ELECTRIC LIGHT & POWER.—The directors' report for the year 1907 states that the equivalent of 3,214 8-c.p. lamps have been added during the year, making the total connections at the end of the year 54,491 8-c.p. lamps. Including the balance of £299 brought forward from last year's account, the statement shows a net profit of £7,221, which, after payment of debenture and loan interest, £2,050, and writing off

Digitized by Google

£79, balance of the cost of the Electrical Exhibition, leaves a balance of £5,092 2s. 6d. available for distribution. An interim dividend for the half-year at the rate of 5 per cent. per annum, amounting to £1,105, was paid in September last, and the directors now recommend that a dividend at the rate of 7 per cent. per annum be declared for the half-year, which will absorb £1,547 16s. 6d., making 6 per cent. for the year; that £1,500 (instead of £1,000 as last year) be placed to depreciation account, and that £627 be placed to reserve fund account, leaving a balance of £313 to be carried to the next account. At the meeting recently the report and accounts were adopted.

YORK TRAMWAYS.—At the half-yearly meeting last week the Chairman stated that the Corporation are now awaiting the confirmation by the Board of Trade of the order recently granted by the Light Railways Commissioners for the extension and conversion of the tramways to electric traction. When this confirmation was received, which might be expected in the course of the next two or three months, the Corporation would under their agreement purchase the company's undertaking.

PARLIAMENTARY INTELLIGENCE

LONDON COUNTY COUNCIL (TRAMWAYS AND IMPROVEMENTS) BILL.—Lord Sanderson presided over a Committee of the House of Lords which had this Bill under consideration on Wednesday last week. Mr. Erskine Pollock, K.C., who appeared for the County Council, said there was only one opposition, viz., the Southwark Borough Council, which asked for the insertion of a clause giving them compensation for the removal of a convenience near Blackfriars Bridge Road on the line of route of tramway No. 7, which connected Blackfriars and Southwark Bridges on the southern side. It was proposed to construct a convenience elsewhere with the amount awarded as compensation, but as this method of procedure would be outside the notices, there was a danger of the Bill being thrown out on Standing Orders, and consequently the County Council could not agree. The committee decided not to insert the clause asked for, and the Bill is proceeding unopposed.

MOTHERWELL BURGH (EXTENSION) BILL.—This Bill has been before a Committee of the House of Commons during the week, presided over by Mr. Luke White. The main object of the Bill is to extend the burgh boundaries so as to include certain districts now outside, which are developing into industrial areas, and which are bound up with the trade of Motherwell. Incidentally, the Bill proposes to extend the limit of electric supply to the new area, and to this there is a certain amount of opposition, objections having been deposited by the Clyde Valley Electrical Power Co. and the Lanarkshire Tramways Co.

PROGRESS OF ELECTRICAL BILLS.—The West London, Barnes & Richmond Tramways Bill, and the London Motor Roadways Bill, are down for second reading in the House of Lords on April 2nd.

The London United Tramways Bill was read a first time in the House of Commons on Thursday.

The Wishaw Borough Electricity Bill has been referred to the unopposed Committee in the House of Commons.

SOUTH WALES ELECTRICAL POWER DISTRIBUTION BILL.—This Bill was before a Committee of the House of Lords, presided over by Lord Wenlock, on Friday. Mr. H. Lloyd, K.C., on behalf of the promoters, first gave the history of the company, and, dealing with the present position, said that a total capital of £800,000 had been raised, a quarter of which was in debentures. The situation was that the whole of the company's resources had been exhausted, their credit was gone, and they were unable to raise any further capital. In 1907, after long negotiations, a scheme was devised which would enable the company to contine its operations, at any rate temporarily. The chief cause of the company's bad condition was that a large number of local authorities, colliery proprietors, and others had been supplied at ruinous rates. The result was that a limited company, being formed with a capital of £100,000 for the purpose of working such parts of the undertaking as could be carried on as a commercial success, but it had been found quite impossible to carry on the generating station at Neath or Brigend, and agreements had been entered into with the Urban District Councils to purchase the station at £7,000 and £3,000 respectively, although in the first place these had cost £40,000 and £30,000 respectively. One of the objects of the present Bill was to receive sanction to these agreements. With regard to the works at Treforest, a limited liability company was working the undertaking, and sanction to this arrangement was also sought, as well as to a similar arrangement in regard to the Cwmbran station. There were creditors to the extent of £85,000, and these they proposed to pay off in preference shares in the statutory company to the extent of £150 of stock for every £100 of debts. The Bill also asked for sanction to modify the existing agreement with the Rhhonda, Llanelly, Mountain Ash, Caerphilly, Abercarn, Neath, and Briton Ferry Councils, all of whom were now satisfied, and did not oppose the Bill. The debenture-holders were supporting the proposals contained in the Bill, and the only opposition was by the local authorities of Aberdare and Pontypridd, who desired to be left out of the company's area. He would conclude by saying that the scheme had been devised with the object of saving the three-quarters of a million of money invested in the undertaking, all of which would be lost if the Bill did not pass. Mr. S. Boulter, on behalf of the debenture-holders, supported the Bill, and Mr. W. A. Chamen, the general manager and engineer, gave evidence as to the progress of the company. He stated that during the whole of their difficulties the consumption of electricity had consistently increased, in spite of the loss of many of the largest consumers in consequence of the uncertainty of the company's position.

The opposition of the Pontypridd Urban District Council, who were represented by Mr. Ram, K.C., was that although they had not a Provisional Electric Lighting Order when the company was originally sanctioned, they now wished to be put in the position of those authorities owning orders—namely, that the company should not come into their area without consent. In cross-examination, Mr. Chamen agreed to give them a clause to the effect that the power company would not attempt to secure customers who took a less consumption than 30,000 units per annum.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., informs us that the price of electrolytic wire bars net c.i.f. port of arrival, quoted on Tuesday night, was £61 5s. to £61 15s. per ton (last week, £59 10s. to £60 per ton).

R. W. PAUL.—Mr. R. W. Paul, the scientific instrument maker, informs us that he has removed from 68 High Holborn, and has opened a new showroom at 33 Leicester Square, where samples of his various patterns of electrical instruments may be inspected. Customers are requested to address all correspondence to Newton Avenue Works, as heretofore.

US LAND AT TRAFFORD PARK.—We learn that one of the largest firms on this estate has decided to offer for sale, at cost price, about 50 acres of its freehold land not required for extensions.

MISCELLANEOUS CITY NOTES

BRUSH ELECTRICAL ENGINEERING CO.—A petition for confirming a resolution reducing the capital of the Brush Electrical Engineering Co., from £650,000 to £489,512, will be heard in the Chancery Division before Mr. Justice Neville on April 4th.

CHARING CROSS, WEST END AND CITY ELECTRICITY SUPPLY.—Applications have been invited during the week for £600,000 4½ per cent. debenture stock at 98. Holders of debenture bonds of the City undertaking, which fall due on January 15th, 1909, are invited to subscribe, in addition to applications from subscribers in cash. The proceeds of this issue will be applied in acquiring all or any of the £337,000 five per cent. bonds falling due as above, in payment of temporary loans secured against similar bonds to the extent of £123,000, and for the general purposes of the City undertaking. The stock now offered will be secured by a trust deed which will create a first floating charge of the City undertaking, the trust deed providing that no mortgage or charge shall be created ranking in priority to or *pari passu* with the stock, but the company is to be at liberty from time to time to issue further debenture stock ranking *pari passu* with the present issue to the extent of one half of the capital expenditure on the City undertaking. The stock falls due on January 15th, 1941, at 100 per cent., but may be redeemed previously at the option of the company, or in case of voluntary liquidation, at 102.

CITY OF LONDON ELECTRIC LIGHTING CO.—Warrants in payment of the balance of dividends for the year 1907 on this company's preference and ordinary shares have been posted.

MELBOURNE TRAMWAY AND OMNIBUS CO.—A dividend of 4½d. per share, equal to 15 per cent. per annum, for the quarter ended March 1st, has been declared.

NORTH METROPOLITAN ELECTRIC POWER SUPPLY CO.—Subscriptions have been invited during the week for 30,000 5 per cent. mortgage debentures of £100 each at par. This is part of an issue of £126,500, of which £96,500 have already been allotted. The debentures are redeemable at 105 per cent. at the option of the company after October 15th, 1914, at six months' notice. The trust deed provides that from January 1st, 1908, a sum of not less than £2,000 per annum shall be set aside out of the company's profits and invested in securities outside the company's business as a reserve fund, and the company undertakes not to realise or create a charge on this fund without the consent of the trustees for the debenture-holders.

SIR W. G. ARMSTRONG, WHITWORTH & CO.—The directors recommend a final dividend making 15 per cent. for the year on the ordinary shares, carrying forward £161,198. Although the dividend is the same as in previous years, the sum carried forward is higher by nearly £60,000.

SOUTH LONDON ELECTRIC SUPPLY CO.—A dividend of 4 per cent. is recommended upon the ordinary shares for the year 1907.

SUMMARY

NEGOTIATIONS are in progress for the sale of the present site and building of the Institution of Civil Engineers to the Government, owing to the projected extension of certain public offices. A scheme is on foot for the acquisition of a new and larger site, at the corner of Great George Street and Princes Street. One of the features of the proposed new building is a lecture hall with greatly increased accommodation. (Page 502.)

THE date of opening of the Electrical Exhibition to be held at Platt Fields Park, Fallowfield, Manchester, has been fixed for October 3rd, and it is to remain open until the end of the month. The preliminary arrangements are well advanced. (Page 503.)

CONSIDERABLE progress has been made with the scheme for securing adequate representation of the electrical industry at the Franco-British Exhibition. (Page 503.)

THE Dublin and Central Ireland Electric Power Bill is now before a Committee of the House of Commons, presided over by Mr. LUKE WHITE. The object of the Bill is the supply of electrical energy over portions of the counties of Kildare, King's County, and Queen's County. Gas engines will be used in connection with 500 kw. generating sets, and the utilisation of peat as a fuel. The promoters estimate that the cost of fuel will be 0·05d. per unit, which is compared with the lowest cost for fuel in England at steam generating stations, namely, 0·13d. at Newcastle and 0·19d. at Salford. It is estimated that there is sufficient peat in the area scheduled to give 35,000 h.p. for 300 years. Captain H. RIALL SANKEY, who gave evidence on behalf of the promoters, stated that whereas it was estimated that the cost of the peat would be 4s. 2d. per ton, the return by the sale of the by-products, sulphate and ammonia, would be 4s. per ton, and other minor by-products were estimated to produce a similar amount, but he did not think it would pay to instal the plant necessary for dealing with the by-products unless a load of 10,000 kw. was obtained. In this event the quantity of peat burned would result in 650 tons of sulphate of ammonia. (Page 503.)

AN article by Mr. J. B. SPARKS contains the results of an investigation made to determine the limiting economical pressures for transmission by underground insulated cables. One example is worked through in order to explain the method adopted in the investigation. On account of the increased cost of the insulation and lead covering at high pressures, and the comparatively small saving in copper obtained by further increasing the working pressure, about 25,000 volts is found to be the

Digitized by Google

maximum economical pressure for the longest practicable distances of transmission. (Page 505.)

The inquiry before Mr. James Swinburne into the proposed electrical regulations of the Home Office was concluded on Thursday, and we give the amended regulations as they now stand. In the final speeches for the objectors, the general position was taken that although an agreement had been come to, to a large extent, upon the details of the regulations, the opinion was still held that no regulations were necessary, and that in regard to the limit of voltage, if the regulations were enforced, this should certainly be raised to 250 volts for both alternating and continuous current. In Mr. Gray's summing-up speech for the Home Office, he said that the only reason he could gather from the opposition that the regulations should not be enforced was that before it could be proved an industry was dangerous there should be a heavy toll of human life. (Page 508.)

The adoption of electrical driving at the South Crofty Tin Mines, Cornwall, has resulted in a reduction of the cost of the treatment of the product to less than half the cost when the mill was steam-driven, and has placed the undertaking, which was formerly unprofitable, on a paying basis. The tin and wolfram ores are separated magnetically, and the whole of the stamp mill and other machinery is now driven electrically. (Page 513.)

A letter from Messrs. Handcock & Dykes criticises the action of the Council of the Institution of Civil Engineers in calling a meeting to authorise a scheme in connection with the proposed new building before the matter has been fully ventilated. The correspondence on telephone matters between Mr. A. R. Bennett and Mr. H. L. Webb is continued, and a letter from the Union Electric Co. relating to no-volt releases for polyphase motors is published. (Page 514.)

The Exhibition of commercial vehicles and motor-boats now open at Olympia contains a few purely electrical vehicles, ranging from omnibuses to carrier tricycles, and several examples of petrol-electric systems as applied to motor omnibuses. (Page 515.)

The water-power plant on the Chicago drainage canal at Lockport at present consists of a group of four 4,000-kw. alternators, driven by horizontal shaft turbines, but provision is made for extensions, bringing the ultimate output up to 32,000 kw. Power is transmitted at 44,000 volts to Chicago over an aluminium line 30 miles long. (Page 517.)

A service of accumulator omnibuses is running in Philadelphia, the garage and battery-charging and repair shops adjoin the generating station, and special appliances are provided for rapidly changing the batteries. (Page 518.)

The design and use of telephone and telegraph trunk cables was dealt with by Mr. F. Tremain in a Paper read last week before the Newcastle Local Section of the Institution of Electrical Engineers. The author discussed the different arrangement of cores possible in paper-insulated lead-covered cables for various numbers of conductors, and went into the question of superimposed circuits, the extended use of which he strongly advocated. A number of practical points were brought out by the various telephone engineers and others who took part in the discussion. (Page 519.)

Some further contributions have been received to the discussion on the Paper read recently by Mr. R. K. Morcom and Dr. D. K. Morris on artificial loads for testing electric generators before the Birmingham Local Section of the Institution of Electrical Engineers, in which several forms of liquid resistance are described. (Page 523.)

Two lectures on "Standardisation" in Mechanical and Electrical Engineering respectively were delivered by Dr. R. T. Glazebrook at the Royal Institution on Thursdays, March 19th and 26th. The lecturer dealt chiefly with the historical side of the matter, but described also in some detail the work of the Engineering Standards Committee. (Page 524.)

Under Electrochemistry and Electrometallurgy attention is drawn to the patent of E. Viel, in which it is stated that aluminium can be successfully obtained from silicates. A note is also given on Dr. Kuzel's work on colloidal solutions and their application to the manufacture of metallic filaments. (Page 525.)

Under Electrical Science, in the British and American Section, appear some notes from the annual report of the Magnetic Department of the Carnegie Institution. An account is also given of Prof. J. J. Thomson's fourth lecture on "Electric Discharges through Gases," at the Royal Institution. It was shown by experiments how secondary ionisation was effected in an ionised gas under the influence of an electric field, by collision between the charged particles and the molecules of the gas, and also between the positive particles and the negative electrode. In the Papers abstracted in the Continental Section, Schild investigates the magnetic properties of electrolytic iron; Dember deals with the fatigue of photoelectric cells; Doglio determines the duration of cathode emission; and Ludewig criticises the theory of electrolytic interrupters. (Page 525.)

The signalling system employed on the newly-opened Hudson River tunnels is of the automatic electrically-worked type. Self-acting train-stops are provided, and at junctions, &c., illuminated track diagrams are used. (Page 526.)

Amongst the Patent Specifications published last Thursday are two by R. A. Fessenden, the first of which describes an improved receiving system for selective wireless telegraphy, and the second of which relates to a method of wireless signalling in which the magnetic component of the electromagnetic waves is used instead of the electrostatic component. In this system, no vertical antenna is required. The British Thomson-Houston Co has one relating to magnetic wedges constructed of iron wire, and another describing an improvement in their system of control for petrol-electric vehicles. A specification by Griffiths and Bedell relates to an improved form of cable for the "G.B." surface-contact system of electric traction. (Page 527.)

The Mexborough, Swinton, and Rawmarsh Urban District Councils are considering the possibility of substituting the overhead trolley system for the Dolter system now being used in their districts. An arrangement has been come to for a supply of electrical energy to be given in Port Glasgow by the Greenock Corporation. A proposition to reduce the number of street arc lamps in certain streets in Newcastle is reported upon adversely by the Tramways Manager and the Lamps Inspector. The new electric lift on the East Cliff at Bournemouth is now in operation. (Pages 529 and 530.)

Derby Electric Lighting Committee estimate their capital requirements during the coming financial year at £7,500. A Local Government Board inquiry has been held at Wimbledon with regard to a loan of £21,000 for electric lighting purposes. Wallasey Council requires automatic overload and reverse-current single-pole circuit-breakers; and the Limerick Council invites tenders for stores. (Page 531.)

Both the South Wales Electrical Power Distribution Bill and the North Metropolitan Tramways Bill were passed by a Committee of the House of Lords last week. The London and Windsor Motor Roads, Tramroads and Tramways Bill has been abandoned. (Page 533.)

The half-yearly report to December, 1907, of Messrs. Willans & Robinson shows a profit at Rugby of £22,946.

Digitized by Google

and a loss at Queen's Ferry of £3,128. For 1907 the South London Electric Supply Corporation is able to distribute £15,479, after meeting depreciation and interest on debentures. (Page 534.)

The present position with regard to the proposed Home Office Regulations as to the use of electrical energy in factories is decidedly peculiar. While still protesting against the imposition of any regulations at all, a Committee of objectors—representing practically every supplier of electrical energy, a number of large electric power users, and the Chambers of Commerce—have been compelled to discuss the regulations already drafted, and to agree provisionally on an amended code which will probably be adopted by the Home Office without much further adjustment if the threat of imposing regulations is put into execution. We publish the amended draft in full this week, and it will be seen that the alterations in form are considerable. Where previously certain precautions were ordered to be taken in every factory in which electricity is employed, some of these safeguards are now only to be introduced compulsorily "where necessary to prevent danger," and other requirements are to be followed "so far as is reasonably practicable." But, although the amendments have certainly relaxed the stringency of the regulations, there is no doubt that the regulations are still in a form likely to give a considerable amount of annoyance and vexation to the supplier and user of electrical energy. We cannot but think that, throughout the detail work of revision, the method that would be employed for enforcing the regulations has not been kept sufficiently in the foreground.

Apparently it is proposed by the Home Office that the existing staff of factory inspectors are to have electrical inspection added to their duties. The rank and file of factory inspectors can perhaps best be classified as highly intelligent, polite, and observant machines. They are not necessarily engineers, and they are certainly not electrical engineers: probably not one factory inspector in ten knows the difference between an electrostatic voltmeter, a no-voltage release, an isolating link, and a transformer. Such men are doubtless eminently capable of seeing that rules as to "fencing" of machinery, the size of workshops, posting-up of regulations and copies of Acts, and similar requirements easy of interpretation are carried out, but they are certainly not able to form judgments on highly technical questions. Yet in the draft electrical regulations as amended the words "so far as is reasonably practicable" and "if necessary to prevent danger" constantly recur, and it is presumably the well-meaning, but in this respect inexperienced factory inspector who is to decide whether each particular precaution is "reasonably practicable," or whether it is "necessary to prevent danger" in the particular case before him. We will imagine a factory inspector of the old school entering an electrically-driven works armed with this code of regulations. He will possibly start conscientiously at Definition 1, and ask for a hot-wire or electrostatic voltmeter to enable him to ascertain whether the pressure is "low," "medium," "high," or "extra high." On being told that there is no such instrument on the premises, he will read through the regulations, and, finding that the provision of such an instrument is not obligatory, will perhaps pass on to another definition and ask to be shown all the "conductors" on the premises, in order that he may see whether they comply with Regulations 1 and 2. He will possibly be told that most of the conductors are in pipes and inaccessible for inspection, and will again wonder when he finds that there is nothing in the regulations forbidding the concealment of conductors in pipes or within walls. Yet this man will have to decide whether all apparatus and conductors are "sufficient" in size and power for the work they are called upon to do, and whether they are protected "so far as is reasonably practicable." He will have to pass judgment as to whether every switch, circuit-breaker, or isolating link is constructed and placed "so as to prevent danger," and whether portable insulating stands, screens, boots, or gloves are "necessary," and, if so, whether those in use are "of such size, quality, and construction, according to the circumstances of the use thereof that a person is thereby adequately protected from danger." In fact, almost every one of the thirty-two regulations requires technical knowledge for its interpretation; the words "adequate," "sufficient," "efficient," "proper," "suitable," are constantly repeated, in addition to the phrases "so far as is reasonably practicable" and "where necessary." The whole idea of placing such regulations as these in the hands of an ordinary factory inspector is not only ludicrous but dangerous.

Serious "electrical" accidents, occasioned by the neglect of proper precautions on the part of the employer or his electrical engineer or contractor, are so rare in this country that no code of regulations or systematic Government inspection is necessary. Were accidents frequent enough and serious enough, however, to call for the enforcement of such regulations as these, an adequate inspection to ensure their proper observance would require an army of fifty or a hundred highly-paid officials, possessing at least equal experience in electrical engineering, tact, firmness of character, and consistency of purpose as has been exhibited by his Majesty's one and only Electrical Inspector of Factories during the six years he has occupied this position.

The Paper on telephone and telegraph cables, read by Mr. F. Tremain before the Newcastle Local Section last week, shows that the design of multiple telephone and telegraph cables has undergone considerable modification at the hands of the Post Office during recent years. In order that each section of cable on a long route may be taken into service as soon as it is laid, and so that the utmost and speediest return can be obtained from the heavy capital expenditure on new lines, cables are now designed to include a number of pairs of comparatively light copper wires which can be used for the short distance work initially, and can subsequently be employed in parallel for long-distance lines. This is but one of the modifications in design dealt with in Mr. Tremain's Paper; the whole essay is worthy of careful study by the telegraph and telephone engineer and the cable-maker. It is surprising that, while progress is made in the design of large multiple cables for underground work, the submarine telegraph cable with its simpler construction and fewer conductors has remained almost unaltered for a quarter of a century. It is true that there have been slight improvements in detail, and that a few comparatively short paper-

Digitized by Google

insulated cables have been laid with success by the German Government, but the great question of constructing a cable with insulation of a much lower specific inductive capacity than guttapercha for long-distance submarine work has remained almost untouched. We are convinced that, by supplementing our present knowledge of the theory of telegraphic and telephonic transmission and of the properties of cable insulating materials, with a certain amount of special experimental research, submarine telephony over far greater distances than at present would be possible, greater telegraphic speeds could be obtained over the next long cables that are laid, and the necessity of retransmission of messages in the case of long routes could be much reduced. The majority of the difficulties to be overcome in the manufacture of submarine cables with lower capacity and higher inductance are purely mechanical ones.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, APRIL 2ND.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at 25 Great George Street, Westminster, S.W. Paper to be read :—"High-speed Electrical Machinery," by G. Stoney and A. H. Law.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton Hall, Westminster, S.W. Paper to be read :—"Efficiency of Boiler-heating Surface," by C. H. Wingfield.

Röntgen Society.

8.15 p.m. Ordinary General Meeting at 20 Hanover Square, W., when the following Papers will be read :—(1) "The Measurements of Short Exposures and Production of Uniform Sparks," by F. H. Glew; (2) "The Technique for Production of X-Ray Negatives by Very Short Exposures," by Dr. P. L. Hope.

SATURDAY, APRIL 4TH.

Royal Institution.

Afternoon Lecture, V., by Prof. J. J. Thomson, F.R.S., on "Electrical Discharges through Gas."

Institution of Electrical Engineers, Manchester Students' Section.

2.30 p.m. Visit to works of Messrs. Browett, Lindley & Co.

MONDAY, APRIL 6TH.

Institution of Electrical Engineers, Newcastle Local Section.

8 p.m. Meeting at the Armstrong College, when the Paper by G. Stoney and A. H. Law on "High-Speed Electrical Machinery" will be read.

Dick, Kerr Engineering Society.

8 p.m. Meeting at Messrs. Dick, Kerr's works at Preston. Paper to be read :—"Elevators," by R. V. Morse.

TUESDAY, APRIL 7TH.

Institution of Electrical Engineers, Manchester Students' Section.

7 p.m. Annual General Meeting at the Municipal School of Technology.

8 p.m. Ordinary Meeting. Paper to be read :—"General Testing," by J. Roberts, Jun.

WEDNESDAY, APRIL, 8TH.

Institution of Electrical Engineers, Birmingham Local Section.

7.30 p.m.—Meeting at the Technical School, Suffolk Street, when the Paper on "New Alternate Current Instruments," by Dr. W. E. Sumpner and J. W. Record will be discussed.

Association of Engineers in Charge.

7.30 p.m. Meeting at St. Bride's Institute, Fleet Street, London. Paper to be read, "Indicators and Indicator Diagrams," by W. A. Tookey.

Royal Society of Arts.

8 p.m. Ordinary meeting. Paper to be read, "Technical Education in America," by Sir William Preece, K.C.B., F.R.S.

Incorporated Institution of Automobile Engineers.

8 p.m. Meeting at the Institution of Mechanical Engineers, St. James's Park, London. Paper to be read, "A System of Costing, Book-keeping, and Recording, suitable for a Motor or other Engineering Factory," by J. S. Napier.

THURSDAY, APRIL 9TH.

L.C.C. School of Photo-Engraving.

8 p.m. Lecture by Sherard Cowper-Coles, on "Some Notes on Electrotyping."

FRIDAY, APRIL 10TH.

Physical Society.

8 p.m. Meeting at the Royal College of Science, South Kensington. Agenda :—(1) "An Experimental Investigation of the Nature of X-rays," by Prof. W. H. Bragg, F.R.S., and Mr. Madsen. (2) "Short Spark Phenomena," by W. Duddell, F.R.S.

Royal Institution.

9 p.m. Evening discourse on "The Carriers of Positive Electricity," by Prof. J. J. Thomson, F.R.S.

SATURDAY, APRIL 11TH.

Royal Institution.

3 p.m. Afternoon Lecture VI., on "Electrical Discharges through Gas," by Prof. J. J. Thomson, F.R.S.

Birmingham and District Electric Club.

7 p.m. Meeting at the Colonnade Hotel, New Street. Paper to be read, "Electrical Train Lighting," by S. H. Bridcut.

Institution of Electrical Engineers, Students' Section.

Visit to the Electric Lighting Station of L.N. & W. Railway, at Chalk Farm.

PROPOSED NEW BUILDING FOR THE INSTITUTION OF CIVIL ENGINEERS

IT has been known for some time, and was stated in the President's inaugural address, that the acquisition by the Government of the present premises of the Institution of Civil Engineers, in which most of the meetings of the Institution of Electrical Engineers are held, was imminent, and a meeting is to be held to-morrow to authorise the council entering into certain agreements in the matter with a view to the sale of the present building and site. The question of a new site has engaged the close attention of the council for a long time past; and after much negotiation and discussion of alternative proposals, they have arrived at an understanding with H.M. Office of Works which will afford the Institution opportunities of improved accommodation impossible to be obtained on the present site. The proposed new site occupies a position at the corner of Great George Street and Princes Street, the latter street being widened at its northern end, and other alterations made in connection with the completion of the public offices which will add to the advantages of that situation.

It has been arranged that the new site shall comprise a considerably larger area than that of the present building; and special attention has been given to the possibility of including within the new building a hall of a character similar to those possessed by the great legal societies, which will afford facilities for the conduct of examinations and the holding of special meetings and gatherings, when the numbers present largely exceed those which the existing building can accommodate, and in which the memorials of eminent engineers may find a place.

In order to provide the additional funds which are considered necessary to avoid drawing upon the invested capital of the Institution to a greater extent than is desirable, and to ensure the additional revenue which the larger building will entail, a scheme has been proposed which will be submitted to the meeting of introducing the payment of a fee of £10 10s. on transfer to full membership, and to make the entrance fee to be paid by those who may be in future elected in the first instance as full members £21. No alteration in the annual subscriptions is proposed. With regard to the building fund itself, about £8,000 has already been promised from prominent engineers, and the council suggest that many of those who are already full members will voluntarily contribute the same additional sum as that proposed to be levied upon those who may hereafter be transferred to full membership.

THE FORTHCOMING ELECTRICAL EXHIBITION AT MANCHESTER

To be held in special buildings at Platt Fields Park, Fallowfield, Oct. 3—31, 1908

SINCE the notice which appeared in Electrical Engineering of March 19th (p. 425), announcing the progress which has been made regarding the arrangements for the holding of an Electrical Exhibition in Manchester next October, and contradicting an unfounded rumour that the scheme was to be abandoned, the movement has advanced a good deal, and we are glad to say that the scheme is now taking definite shape, and that a number of details have been settled. A meeting of the general committee organising the exhibition was held in the Electricity Committee Room, Town Hall, Manchester, on Tuesday, March 24th, when the executive committee reported fully as to their proceedings up to date, and it was unanimously resolved to confirm the recommendations of that committee and to proceed with the final details in connection with the holding of the exhibition.

The Secretary was instructed to enter into a contract with the Manchester Corporation for the use of Platt Fields Park, Fallowfield, as the site, and to accept the lowest tender received for the erection of the necessary buildings. These buildings have been licensed by the Manchester Corporation for one year, and the plans have been passed by the city architect.

In the meantime a draft prospectus and plans of floor space available for exhibitors had been prepared, and already the large number of applications and inquiries for space, indicate the prospect of a thoroughly representative exhibition, and are very encouraging. The Secretary has been instructed also to enter into the necessary contract with the Manchester Corporation Electricity Committee for a full supply of electrical energy, and it will be of interest to intending exhibitors to know that, in addition to a 200-volt continuous-current supply for lighting, there will also be available for power purposes either continuous current at 400 volts, or a three-phase alternating supply at the same voltage.

A preliminary prospectus or circular has been approved, and will be circulated forthwith, and rules and regulations, with a plan of the floor space available, are in course of preparation.

It has now been definitely decided that the exhibition shall open on Saturday, October 3rd, and close on Saturday, the 31st of the same month. The committee have appointed Mr. S. G. Castle Russell as honorary consulting electrical engineer, and Mr. Albert Jennison, Deansgate Arcade, Manchester, consulting architect.

We are glad to see such evidences of the vitality of the scheme, and it is very satisfactory to learn that the activity of the members of the committee, and the interest which is being taken in the project by all branches of the electrical industry, has placed the undertaking in such a position that its success is now assured—a success which cannot fail to be of mutual benefit to all those who participate in it.

THE FRANCO-BRITISH EXHIBITION

Co-operative Electrical Exhibit

WE are pleased to be able to announce that a good deal of progress has been made with the movement for ensuring a thoroughly representative and effective demonstration by the electrical industry at the forthcoming Franco-British Exhibition at Shepherd's Bush. The committee which was formed with this object by the Institution of Electrical Engineers have acquired a space of about 7,000 square feet, upon which it is intended to erect four fireproof pavilions, in and around which will be exhibited electrical apparatus of every description in general use. A meeting was held last Friday, at which about twenty of the largest electrical firms made formal application for space, and a circular and plan of the exhibition stands is being prepared to send out to those firms who have already expressed their intention of taking part in the exhibit but were prevented from being present. The committee are anxious to receive the names of other firms who are desirous of taking part in the movement. The space now available is rather limited, as nearly half has already been allotted. Applications, which should be addressed to Mr. C. S. Northcote, 2 Queen Anne's Gate, Westminster, S.W., are obliged to be dealt with in strict rotation, and it is anticipated that within the next week or ten days, the whole of the space will be taken up. The committee of conference of chief officials of the London Supply Companies have donated a substantial sum of money towards the cost of this electrical display, and although it is the first co-operative exhibit arranged for the electrical industry, its success seems likely to be undoubted, and the cost to individual exhibitors is, on account of the combination of interests, quite nominal. The committee are particularly desirous of obtaining offers from manufacturers of incandescent lamps or cooking apparatus which may be exhibited, to arrange for demonstrations of lamp-making, heating, and cooking, and it is hoped that an effective combined exhibit will be got together.

ELECTRICITY FROM PEAT

Dublin and Central Ireland Electric Power Bill

THE House of Commons Committee, under the chairmanship of Mr. Luke White, commenced consideration of this Bill on Monday. Counsel for the Bill were Mr. G. M. Freeman, K.C., Mr. Roger Wallace, K.C., Mr. Jeeves, and Mr. Seely. The opponents to the Bill are the Dublin Corporation, County of Dublin County Council, Rathmines and Rathgar Urban District Council, Pembroke Urban District Council, Dublin United Tramways Co., Alliance and Dublin Consumers Gas Co., and the Blackrock Urban District Council.

Mr. Freeman, K.C., in opening the Bill, said its object was to incorporate a company to supply electrical energy over an area in Ireland comprising portions of the counties of Dublin, Kildare, King's County, and Queen's County. A main generating station will be erected upon the Grand Canal, close

Digitized by Google

to Robertstown. This canal forms a highway practically throughout the whole of the proposed area of supply, and it is interesting to note that the promoters of the Bill have made arrangements with the owners of the canal for carrying overhead wires along the banks. Owing to the presence of peat in the district, it was intended to make use of a process which was not familiar in this country, but was very familiar in other countries on the Continent. Gas engines would be used, supplied with peat as fuel, and arrangements had been made with an owner for the purchase of about 500 acres of the nearest peat bogs to the generating station; and the depth of peat available on this land would enable the promoters to supply for a great number of years, even on a most favourable assumption of the business they were likely to procure. Even were this supply to be exhausted, there were plenty of other bogs in close proximity, and these other lands were situated upon such an incline that it would be possible to get the peat by mechanical means to the works, at a very low cost. The great difficulties hitherto in reference to the utilisation of peat, continued counsel, had been the amount of moisture—about 90 per cent. was the correct amount—found in the peat, and if this were dried, the expense of doing so was too great in proportion to the return. But under the process now commonly used in Germany and various other parts of the Continent, it was not wise to dry the peat too much, as for economical working it was necessary to have 50 per cent. or 60 per cent. of the moisture in the peat. The surplus moisture was dried out by leaving the peat in the sun and in the handling on the way to the works, so that without any artificial drying the peat was got into the receivers at the works. It was estimated that the cost of fuel would be 0·05d. per unit, and this cost was compared with the two lowest fuel costs in England, viz., 0·19d. per unit at Salford, and 0·13d. at Newcastle. Sulphate of ammonia would be recovered in the process, and it was estimated that the cost of the peat would be met by the return from the by-product. The capital is £450,000 in shares and £150,000 in borrowing powers. Dealing with the amount of support which the Bill is receiving it was stated that the Dublin Industrial Development Association, which is an association endeavouring to encourage and attract fresh trade to Ireland, was in favour; the Dublin Lucan Tramways Co. was willing to take a supply; the Dublin and Blessington Tramways would favourably consider the taking of a supply; an agreement had been made with the Blackrock Urban District Council for giving a supply, subject to the Bill being passed; and the Kingstown Urban District Council and Rathdown Union were also in favour of the Bill. The fact that at present there were few industries in the proposed area was no argument against the scheme, for at Niagara, when that scheme was first thought of, there was not a factory within 50 miles, but in a very short time the whole district was filled with industries. The industries which, it was hoped, would be attracted to Ireland were the electro-chemical and electro-metallurgical industries. Dealing with the opposition to the Bill, Mr. Freeman said the Dublin Corporation, which wished to be absolutely excluded, was protected by the clause under which the company could not supply there without consent, with an appeal to the Board of Trade. The view of the promoters was that the plant of the Dublin Corporation was obsolete, and they had no doubt that in the course of time the Corporation would be only too pleased to come to terms for a supply in bulk. The opposition of the County of Dublin County Council was both unreasonable and unprecedented, for, although it had no powers to supply electricity itself it asked that no supply should be given by the company without consent. The general position taken up by the promoters was that all towns giving a supply of electricity should be asked for its consent before a supply is given, subject to an appeal to the Board of Trade in the event of the consent being unreasonably withheld.

Mr. John Sturgeon, civil and mechanical engineer, of Leeds, who has been connected with the Niagara, Lancashire, Yorkshire, and Belfast power schemes, was then called. With regard to the latter scheme, he stated it had been taken over by Dr. Mond, who was now erecting a generating station at Portadown, which would be driven by gas engines utilising peat in the same way as was proposed by this Bill. The area of the proposed scheme is 1,460 square miles, and included 7,000 acres of bog land. The area also included 121 miles of the Grand Canal. The depth of the bog of which it was proposed to purchase 500 acres was 25 ft., and this would be sufficient for 15,000 h.p. for 50 years at 30 per cent. load factor; whilst the whole of the 7,000 acres of bog would give 35,000 h.p. for 300 years. There was a fall in the bog towards the station of 25 ft., so that it would not be a difficult matter to transport the peat. The equipment of the first portion of the generating station would be 12,000 kw., of which he estimated that 7,000 kw. would be taken up on the spot for electro-chemical and electro-metallurgical works. The generators would be in 500 kw units, this size being fixed as the limit having regard to the efficiency of gas engines at the present time. The promoters were actually in treaty for the erection of a calcium carbide works. He had provided in his estimate for 125 miles of trunk mains in the first instance.

The details of his estimates are as follows:—Costs of Act, stamp duty on capital issue, prospectus and flotation costs £14,000; underwriting on first issue of £200,000 at 7½ per cent., £15,000; interest during construction, 3 per cent. on £100,000, £3,000; purchase of land and bog, drainage, levelling, fencing, and preparing land for buildings, &c., £5,250; buildings and foundations, shedding, &c., £15,000; cost of producers and washing plant for 16,000 h.p., £52,000; gas engines and generators in units of 500 kw., switchgear, &c., £159,600; piping, pumping machinery, and conveying plant, trucks, tools, &c., £20,000; repairing shop with tools, &c., £3,000; wharf crane, travelling cranes, and other lifting tackle, £3,000; sub-stations for 6,000 kw. with static and rotary transformers,, switchgear, &c., £60,000; overhead main lines, 125 miles, 44 poles per mile at £210 per mile, including wayleaves, branches to consumers, accessories and contingencies, &c., £261,260; 125 miles overhead copper wire to transmit 5,000 kw. distributed over four miles, averaging, say, £0·6 per kilowatt per mile with accessories, contingencies, &c., £187,500; wiring to consumers in vicinity of generating station, say, £12,500; engineering, legal, contingencies, and cash balance in bank, £43,890. Total, £600,000.

On Tuesday, in the course of cross-examination, Mr. Sturgeon strongly objected to cutting Dublin out of the area altogether. Owing, he said, to the insertion of such a clause in the Belfast and North East Ireland Power Bill, as regards Belfast, the promoters of that Bill had been unable to place the scheme before the public in the ordinary way, and the carrying out of the undertaking had been considerably delayed thereby. The costs of 0·05d. per unit which he had already given were fuel costs only; the total cost of generation was estimated at 0·12d. per unit. The cost of procuring the peat based upon the prices at present charged by the existing peat cutters was about 5s. per ton. The main success of the scheme would depend very largely upon new industries being commenced in the area, but they also regarded the supply to existing authorities as being a substantial factor. An agreement had been entered into with the Blackrock Urban District Council at a 1½d. per unit, decreasing to 1d. per unit according to the load factor.

Mr. H. Riall Sankey, R.E., said he had been studying the question of the utilisation of peat in connection with gas engines for the past two years, and had visited Germany and Sweden and investigated the methods there used. The estimates of the promoters, with which he agreed, had been based upon using existing methods of dealing with the peat and the cost came out at 4s. 2d. per ton. A new process had been invented by Zeigler, however, which would reduce this to 3s. per ton. He calculated that 2·2 lbs. of peat would produce one unit of electricity. One of the great advantages of utilising peat for the manufacture of gas was that pre-ignition did not occur, there was less sulphur and the products of combustion were much more friable than with ordinary gas. The calorific value was very slightly less than that of Mond gas, which was 148 units per cubic foot. The lowest for peat gas was 128, but he had found it to be as high as 140. It was estimated that the sale of the by-product, sulphate of ammonia, would realise 4s. per ton, and so practically balance the cost of the fuel, whilst the other by-products in the aggregate would probably give the same return per ton, so that there would be actual profits made on the by-products alone.

In cross-examination, it was put to Captain Sankey that if the sale of by-products was to be such a remunerative thing, the question of electricity supply need not enter into their calculations at all, and the extra profit on this might be regarded as so much pocket money. Captain Sankey replied that the scheme was put forward mainly for the purpose of electricity supply, and he only mentioned these figures to show the possibility of the scheme paying. He quite admitted that it would be commercially possible to make the gas and blow it into the air simply for the sake of the by-products if a sufficient quantity would be sold. He did not think, however, it would pay to instal the plant necessary for dealing with the by-products unless 10,000 kw. of electrical energy were sold, which would be equivalent to 26,000,000 units, and the quantity of peat burned would result in 650 tons of sulphate of ammonia. There were several installations in Sweden and Germany using peat for gas engines, but none for giving a public supply of electricity. He mentioned that in connection with the manufacture of nitric acid from the air one important company which was now making experiments in Sweden had expressed its willingness to carry out similar experiments in Ireland if this scheme went through.

The proceedings before the committee will occupy several days.

In this connection reference may be made to the lecture by Mr. A. B. Lennox before the Dublin Local Section of the Institution of Electrical Engineers, in December, on the getting and drying of peat with a view to its use for the generation of electrical energy, in which a special form of grab dredger and drying apparatus was described, together with the complete method of preparing the material for use in gas producers. Estimates were worked out for the cost of preparing peat ready for the producer, which was given as £5 19s. 2d. per 50 tons, and the capital cost of an installation to turn out 50 tons per day was put at £5,000. The Presidential address of Mr. T. Tomlinson, the chairman of the Dublin Local Section, was also devoted to the same subject (Electrical Engineering, Vol. II., pp. 1029 and 859.)

ECONOMICAL PRESSURES FOR POWER TRANSMISSION BY UNDERGROUND CABLES

By J. B. Sparks

IN the discussion of such an interesting subject as the construction of extra high-tension insulated cables, one is apt to overlook the fact that, although it is quite possible to construct insulated cables for working pressures of 50,000 volts or more, it may be more economical to employ cables of larger copper section and for lower working pressures. For any given transmission scheme, the most economical pressure for the transmission line will depend not only on the cost of the cable, but also on the cost of the transformers and the high-tension switchgear; and having estimated the most economical pressure for the cable line, considering only the cable, we must reduce this somewhat in order to obtain the most economical pressure with regard to the whole plant.

In order to obtain some general idea as to how the cost of the cables is affected by raising or lowering the working pressure of any proposed transmission line, let us take a particular case of the transmission of a certain amount of power over a certain distance under a few assumed, definite, and simple conditions, and work out the actual cost of the cables for different working pressures. A suitable case for such a comparison is the following:—

An annual transmission of 50 million kilowatt-hours over a distance of 31 miles by three-phase alternating-current through two three-core insulated cables laid underground. Power-factor 0·9, and load-factor 0·5. Cost of energy at the generating end of the line, 0·5d. per kilowatt-hour. The average load on the line will thus be:—

$$\frac{50{,}000{,}000}{365 \times 24} = 5{,}700 \text{ kw.}$$

Assuming that the load is equally divided between the two cables, the average load per cable will be 2,850 kw. The load per phase on each cable will be 950 kw.; or with a power-factor of 0·9, some 1,060 kva. Let us estimate the cost of such a cable for four different working pressures, viz., 5,000, 10,000, 20,000, and 40,000 volts between cores. The average kilovolt-amperes per cable per phase are 1,060 kva. in each case, and consequently the average currents per core will be 368, 184, 92, and 46 amperes respectively.

The next step is to decide the section of copper per core in each case. The chief factor determining this, in the case of such a long transmission scheme as that under consideration, is not the heating, but the cost of the energy wasted in transmission. A careful investigation has shown that in the particular case in question the most economical annual efficiency of the line would be from 88 to 98 per cent. The higher the working pressure, the higher is the most economical line efficiency. Thus for a working pressure of 10,000 volts between cores, the most economical efficiency works out at about 89 per cent.; but for 30,000 volts it is found to be about 96 per cent. Were the cost of the energy at the generating end of the line less than 0·5d. per kilowatt-hour, the most economical efficiencies would, of course, be lower than the above.

In order to simplify the present investigation, let us assume an annual loss of 5 per cent. of the energy delivered in all four cases. (This corresponds to an annual line efficiency of 95·2 per cent.) A total loss of 5 per cent. is a loss of 0·161 per cent. per mile of cable for all three phases, or

$$\frac{2{,}850 \times 0{\cdot}161 \times 1{,}000}{100} = 4{,}590 \text{ watts per mile per cable,}$$

or 1,530 watts per mile per core. This loss is really made up of two items: the copper loss and the loss due to hysteresis in the dielectric. We can, however, neglect the latter for the present purpose, especially as its introduction into the investigation would only strengthen the resulting conclusions.

Now, assuming that the copper loss per mile of core is 1,530 watts at 5,000 volts between cores, and therefore 368 amperes per core, the resistance per mile per core will be

$$\frac{1530}{(368)^2} = 0{\cdot}0113 \text{ ohm.}$$

The specific resistance of copper at the temperature at which the cables will work (say 85° F.) is about 0·715 microhm per cubic inch. Therefore,

$$\text{section per core} = \frac{1760 \times 3 \times 12 \times 0{\cdot}715}{0{\cdot}0113 \times 10^6} = 4{\cdot}0 \text{ sq. in.}$$

The necessary sections at the different pressures are tabulated, together with the weight and cost of the copper, in Table I.

Table I.

Volts between cores.	Current per core.	Ohms per mile per core.	Section per core. sq. in.	Tons of copper in 31 miles of one 3-core cable.	Cost of copper in one cable at £100 per ton. £
5,000	368	0·0113	4·0	3,520	352,000
10,000	184	0·045	1·0	880	88,000
20,000	92	0·180	0·25	220	22,000
40,000	46	0·725	0·0625	55	5,500

The maximum practical section per core for a three-core cable is some 0·6 sq. in.; consequently, in the case of the 10,000-volt transmission we should require four three-core cables; and in the case of the 5,000-volt transmission we should require some 12 or 14 cables. However, for the sake of simplicity let us assume that three-core cables having sections per core of 1·0 and 4·0 sq. in. are possible. A sub-division into a number of insulated cables would strengthen the argument here set forth.

Before proceeding further, let us make sure that the cables will not overheat. The current density is greatest in the case of the 40,000-volt cable, where it is 740 amperes per sq. in. If the load-factor of the system were 0·5, then the maximum current density would be 1,480 amperes per sq. in. For such a cable (*i.e.*, 0·0625 sq. in. per core, three-core high-tension cable laid underground) the value of 1,480 amperes per sq. in. will not cause the cable to overheat.

The figure of £100 per ton as the cost of the conductor is taken to include the costs of wire-drawing, stranding, &c. This is rather too high for present market prices, but a lower figure would only strengthen the argument.

The figures of Table I. only illustrate the well-known fact that if we double the pressure and thus halve the current, we require only one-quarter of the weight of copper for equal loss. It will be noticed, however, that whereas by raising the pressure from 5,000 to 10,000 volts we save £264,000 on the copper for each cable, by raising the pressure from 20,000 to 40,000 volts we save on the copper only £16,500 per cable; and it is the purpose of this investigation to show that the saving on the copper in the latter case will be quite offset by the extra cost of the insulation due to the higher pressure employed, and that it is not economical to work at such high pressures.

The effect of the increasing pressure on the total cost

Digitized by Google

of the cable is shown by the curves in Fig. 1, which express the ratio of the total works cost of the complete cable to the cost of the contained copper for three-core high-tension lead-covered cables as a function of the pressure in kilovolts between cores, when the cost of the copper (including wire-drawing, stranding, &c.) is £100 per ton. From these curves it is evident that at high pressures and small sections the cost of the copper is such a small fraction of the total cost of the cable that a decrease in section and in cost of the conductor is quite offset by the accompanying increase in quantity, quality, and cost of the insulation necessary to withstand the higher pressure.

The total cost of a cable, as obtained from the curves of Fig. 1 includes the cost of the lead covering, the cost of lead being taken at £20 per ton. The cost of the insulating material, which, except for the very high pressures, would consist entirely of impregnated paper, was taken at from £40 to £60 per ton, increasing with the pressure.

For the particular case under consideration the total

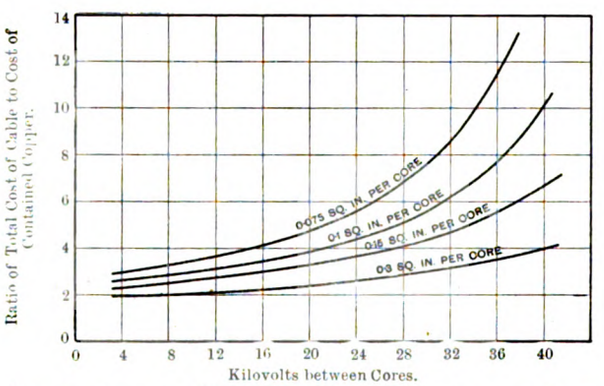

Fig. 1.—Ratio of Total Cost of Cable to Cost of Contained Copper for Three-Core High-Tension Cables, for Various Copper Sections per Core.

costs of the cables have been estimated with the aid of the curves of Fig. 1, and the results are tabulated in Table II.

Table II.

Volts between cores.	Copper section per core, sq. in.	Cost of copper in 31 miles of 3-core cable. £	Ratio of total cost to cost of copper.	Total cost of one 3-core cable (length =31 miles). £	Cost per mile. £
5,000	4·0	352,000	1·3	460,000	14,800
10,000	1·0	88,000	1·5	132,000	4,260
20,000	0·25	22,000	2·75	60,500	1,950
40,000	0·0625	5,500	16·0	88,000	2,840

The values of the cost of cable per mile, given in the last column of Table II., are plotted in Fig. 2 as a function of the pressure in kilovolts between cores.

These cables are for an average load of 2,850 kw. per cable. Curves corresponding to other quantities of power transmitted are given in Fig. 2 for the sake of comparison, and they correspond to cables for 4,500, 1,500, and 300 kw. average load, all capable of transmitting these amounts of power with a loss of 0·161 per cent. per mile. Thus, for example, a cable corresponding to any point on the 1,500 kw. curve would be capable of transmitting 1,500 kw. to a distance of 31 miles with an annual loss of 5 per cent. of the power delivered or an annual line efficiency of 95·2 per cent. We could transmit along this same cable half the power to double the distance at the same efficiency.

Returning to the particular case under consideration, *i.e.*, the transmission of 2,850 kw. per cable to a distance of 31 miles, it will be seen that the most economical pressure, considering only the cost of the cable, is about 25,000 volts between cores. For larger amounts of power transmitted per cable the most economical voltage will be only slightly higher. For smaller amounts of power the most economical voltage will be less.

If the power is cheaper than 0·5d. per kw.-hour at the generating end of the line, then we can afford to

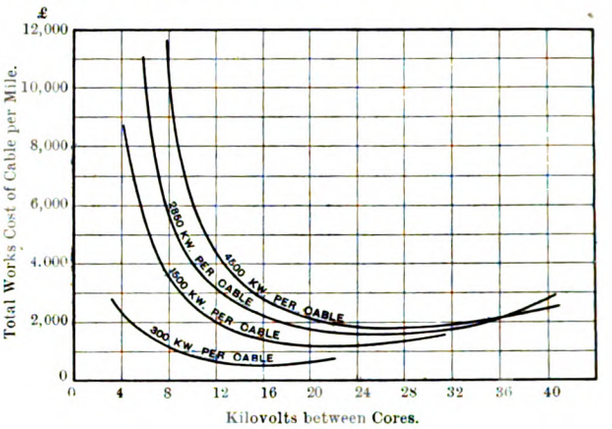

Fig. 2.—Cost of Three-Core Cable for Transmitting Different Amounts of Power per Cable at Different Voltages between Cores and with a Loss of 0·161 per Cent. per Mile.

waste more in transmission, and the most economical efficiency will be lower or the loss per mile more. This means that a smaller section of copper is required, and consequently the most economical voltage will be less than that corresponding to the higher line efficiency.

From these considerations we arrive at the conclusion that it will rarely be economical to employ a higher pressure than 25,000 volts between cores. A higher pressure would be the most economical only in exceptional cases of large amounts of power transmitted per cable to very long distances. In the interests of a reliable supply it is advisable to keep down the amount of power transmitted per cable, and a very long distance underground transmission is rarely practicable, as it involves such an excessive capital cost. In such cases one can only consider an overhead line as the practicable proposition.

The effect of the heavy capital cost of the line on the cost of the energy at the receiving end of the line

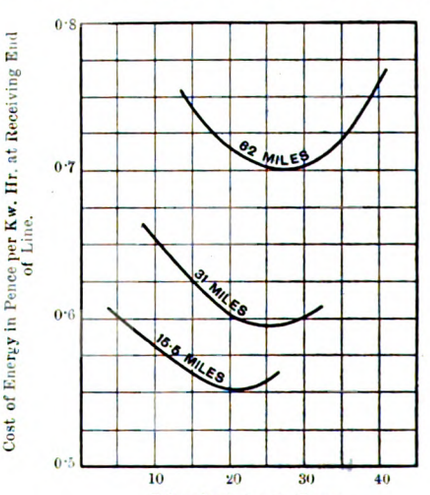

Fig. 3.—Curves showing the Effect of Varying Distance and Voltage on the Cost of Energy at the Receiving End of an Underground Line for Transmitting Fifty Million Kilowatt Hour per Year. Cost of Energy at Generating End of Line 0·5d. per Kilowatt Hour.

is clearly shown in Fig. 3, in which curves are given of the cost per kw.-hour at the receiving end of the line, expressed as a function of the pressure in kilovolts between cores, and for distances of transmission of 15·5, 31, and 62 miles. For the 15·5 mile trans-

Digitized by Google

mission, the minimum cost is obtained at a pressure of 20,000 volts, for 31 miles at a pressure of 25,000 volts, and for 62 miles at a pressure of 27,000 volts.

In all cases and at all voltages the cost per kw.-hour, given in Fig. 3, is the minimum obtainable, *i.e.*, that corresponding to the most economical efficiency of the line. The most economical efficiency of the line will, of course, vary with the cost of the energy at the generating end of the line, the distance of transmission, and the pressure employed.

The cost of the energy per kw.-hour at the receiving end was calculated as follows:—

The annual expenditure on the transmitted energy is the sum of the cost of the wasted energy, and the interest, maintenance, and depreciation of the transmission line; this second item (*i.e.*, interest, maintenance, and depreciation) may be taken as 12 per cent. of the capital cost of the line, including cables, conduits, excavation, and filling in, &c. In the case of overhead lines this figure should be taken somewhat higher. Thus the value of 16 per cent. was assumed in the calculations for Fig. 4. This amount, together with the cost of the energy wasted in transmission, must be divided by the total number of kw.-hours delivered, and

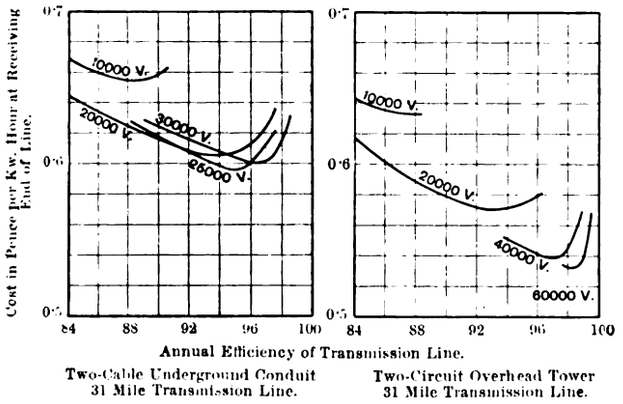

Fig. 4.—Influence of Line Efficiency and Pressure on Cost of Energy at Receiving End of Line.

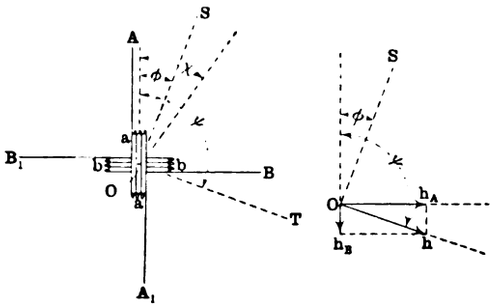
the quotient (which will be some small fraction of a penny) added to the cost per kw.-hour at the generating end of the line.

Thus, for our specific case of a 31-mile transmission at 25,000 volts, the cost of the energy at the receiving end of the line from Fig. 3 is 0·595d. per kw.-hour, 0·5d. being the cost of generation per kw.-hour, and 0·095d. the cost of transmission per kw.-hour.

The influence of the annual line efficiency on the cost per kw.-hour at the receiving end is shown graphically in the curves of Fig. 4. From these curves we find that the most economical line efficiency for the 31-mile transmission under consideration is about 95 per cent. for a pressure of 25,000 volts. At a lower voltage—for instance, 10,000 volts, which means a heavier capital cost—it is economical to waste more power in transmission, and the efficiency for which the transmission cost is a minimum is about 89 per cent.



The left-hand curves are for underground lines, the right hand for overhead steel-tower lines. Comparing these curves, we see that whereas the most economical pressure for an underground cable line, in the case considered, is about 25,000 volts, a pressure of 60,000 volts or more will give the most economical results when an overhead steel-tower line is used.

The capital cost in the latter case is also very much less, and the cost of transmission comes out at 0·032d. per kw.-hour at 60,000 volts, against 0·095d. per kw.-hour for the 25,000-volt underground line. In neither case, however, has any allowance been made for the annual wayleaves or compensation charges, and these, of course, would be higher in the case of an overhead line passing through a populous district. The higher percentage charges for maintenance in the latter case were included in the 16 per cent. "interest, maintenance, and depreciation" mentioned above.

There seems, therefore, no necessity for the construction of three-core three-phase cables for higher working pressures than about 25,000 volts, for cases of transmission over long distances by insulated cables. There is, however, a very useful field for extra high-tension cables, whether for continuous or alternating current transmission, in carrying underground the last few miles of a long overhead transmission line, where this line enters or passes through a town or other densely populated district in which the conditions do not allow of an overhead line. Such use has already been made of extra high-tension cables in France, where the last 2·8 miles of a 112-mile overhead transmission line from Moutiers to Lyons is carried underground. Both alternating and continuous current systems are in use, the voltage between cores for the three-phase three-core cables is 26,000 volts, and the continuous-current cables work at 60,000 volts.

In conclusion, the author wishes to state that this investigation has been carried out at the suggestion of Mr. H. M. Hobart and under his direction, and that this article, embodying the main conclusions, has been published at Mr. Hobart's request.

The Bellini & Tosi Directive System of Wireless Telegraphy.—Our attention has been called to slight errors which occurred in the lettering of the angles in the diagrams forming Figs. 1

and 2 of the article entitled "Directive System of Wireless Telegraphy," by Messrs. E. Bellini & A. Tosi, on p. 348 of our issue of March 5th. In order to make the matter quite clear, we give the diagrams in their corrected form herewith.

Forthcoming Mining Exhibition.—A mining exhibition is to be held at Olympia during July. Several electrical firms have already signified their intention of taking space, so that the applications of electrical working to mines should be well represented.

Damage to City Electric Light Standard.—In the King's Bench Division of the High Court, last week, an action was heard by the City of London Electric Lighting Co. against the Vanguard Motor 'Bus Co., for damage done to an electric light standard at the junction of Threadneedle Street and Old Broad Street. The lamp in question was knocked down by a skidding 'bus on two occasions in June last year, and negligent driving was alleged. The City of London Electric Lighting Co., was awarded £43 3s. 4d. damages in respect of the first accident, a stay of execution being granted with a view to an appeal.

State Control of Wireless Telegraphy in America.—A Bill has been introduced into the American legislature, requiring a federal license for foreign and inter-state communication by wireless telegraphy, which is to be put completely under the jurisdiction of the government. The license can be abolished by the President in times of war. The Bill imposes a license on land stations of $100 a year, and a license of $5 a vessel on all equipped with wireless apparatus. The most severe penalty is provided for interference with messages sent or intended for government officials, or the malicious use or operation of wireless instruments under license by the government. Another feature is a provision that makes it compulsory for all licensed wireless operators to act as relays for messages received by them. The act makes it the duty of every person or corporation using or operating wireless installations under a license issued by the United States to answer wireless calls and signals from any other person or corporation so licensed. According to the *Electrical World*, there is considerable opposition to the Bill.

THE PROPOSED HOME OFFICE REGULATIONS

(Special Report. Strictly Copyright)

THE inquiry before Mr. James Swinburne, F.R.S., into the regulations proposed by the Home Office in connection with the use of electricity in factories and workshops was concluded on Thursday, after a public hearing lasting ten days, in addition to a private conference between the objectors and the Home Office, which also lasted for several days. In our last issue we had reported the proceedings to the eighth day, Tuesday, March 24th.

WEDNESDAY, MARCH 25TH.—NINTH DAY.

Mr. Vesey Knox, continuing his speech on behalf of the Newcastle and other power companies, and the Mersey Docks and Harbour Board, with regard to exemption from prosecution, said his clients were anxious to have it made quite clear that they could only be prosecuted for contravention of the rules if a certificate had been granted by the chief electrical inspector. Unless the amendment he had proposed on the previous day, or something equivalent to it, was inserted, his clients felt that the regulations would be a serious menace to the electrical industry.

Mr. Swinburne asked if the contention was that the Home Office should practically certify that proceedings ought to be started. If so, this really bound the Home Office to commence proceedings, for it would place them in a somewhat illogical position if they certified that the rules were not complied with and then did not prosecute.

Mr. Vesey Knox replied that it would meet his point equally well if the regulations stipulated that unless the electrical inspector had certified that an occupier had, in his opinion, acted in contravention of, or failed to comply with the regulations, no prosecution should take place. He was not arguing so much for the particular words as for the principle, for he attached the utmost importance to the *fiat* of the electrical inspector, as otherwise anybody could put the law in motion against an occupier, and it would be an intolerable nuisance. The statement of law prepared by Lord Robert Cecil on this point, clearly showed that at present absolutely any member of the public could prosecute, and he thought there was no dispute with the Home Office on this point. A way out of the difficulty might be a memorandum calling attention to section 17 of the Factory Act of 1901, which gave the Home Office powers to prosecute for a breach of any regulation. As to the appeal from a decision of a factory inspector, he did not ask for an appeal on every detail, but where, as to past and future work, any requirements under these regulations involved a considerable expenditure of money, there should undoubtedly be an appeal to an independent expert, and his main reason for this was that an electrical inspector might very easily become the prey of inventors. A glaring instance of this occurred in connection with automatic couplings on railways a few years ago, when the Board of Trade was inclined to insist upon these being adopted on all railways. It seemed that an official thought a thing he had seen in America was a very useful invention, and ought to be applied without regard to English conditions, at very great expense. There had to be a Parliamentary agitation to prevent this. Nothing could be more significant on this point than the evidence as to no-voltage releases on three-phase motors. Mr. Garside wanted to have these imposed upon everybody, and if it had been in the power of the electrical inspector only, it was quite clear from Mr. Ram's evidence, they might have been imposed upon everybody. He urged for an appeal to arbitration on the ground that experience showed this was a much less expensive form of appeal than that before magistrates. Generally speaking, the effect of an arbitration clause tended towards agreements without arbitration, and an example of this was that although there was an arbitration clause in the Factory Acts with regard to means of escape from fire in buildings, there had not been more than twenty or thirty arbitrations, and the general effect was that owners had not been put under arbitrary provisions. He therefore proposed that a clause should be inserted stating that where in order to satisfy any requirements of the inspector, an expenditure of more than £100 would be involved, either in an individual case or as applied to a principle, the person required to incur the expense should have the right of arbitration as between the Secretary of State and himself, and that the Arbitration Act of 1889 should apply. The arbitrator's award would be regarded as final.

Mr. Swinburne asked that, if a company had a switchboard, the alteration of which would involve an expenditure of say £90, and also had a large number of other similar switchboards in other parts, did Mr. Knox suggest that one arbitration should cover the lot?

Mr. Vesey Knox replied that he thought in these circumstances, one arbitration could be held as a sort of test case, to which everybody else similarly placed would adhere in the future. As a result of an arbitration, for instance, in connection with no-voltage releases, the Home Office could then issue a statement saying that in particular circumstances no-voltage releases must be fixed.

Mr. Swinburne questioned whether the Home Office could do this, as once the regulations were passed, they would be fixed until there was another inquiry.

Mr. Vesey Knox thought that such a notice would be a rule under the regulations, and would not be made as a new regulation. In this way he thought that a number of persons could combine together for the purposes of an arbitration upon a matter of principle. He felt the absolute necessity for taking such matters before an expert in preference to magistrates. With regard to Exemption 5, he did not regard this as at all satisfactory, as it put the onus on the occupier of proving that there were special conditions which took him out of the regulations, and he thought the addition of the words "as far as is reasonably practicable" was essential.

Mr. Swinburne suggested that Mr. Knox might consider this from the point of view of an occupier, who was putting up new work, and who would naturally wish to know how he stood with regard to the regulations in respect of the design which he was adopting.

Mr. Vesey Knox said he saw no way out of this difficulty except by a system of approval of plans by the Home Office. To have this done, he thought the industry would be brought almost to a standstill, whilst at the same time he thought it would be impracticable to approve every plan throughout the country. For this reason he saw no alternative but to leave this element of risk remaining. At the same time, he regarded it as a strong argument for restricting the scope of the regulations as much as possible. Dealing with the question of voltage, Mr. Vesey Knox stated that so far as the Mersey Docks and Harbour Board were concerned, they would be safe if the limit was raised to 250 volts; if not, then he thought there was a good deal to be said for omitting docks. The law at present with regard to docks was most obscure, and the introduction of the "authorised person," which he had already referred to, involved a problem which he could not solve.

Mr. Gray mentioned that Mr. C. P. Sparks had made some investigations on the question of whether resuscitation by artificial respiration had been successful in any case.

Mr. Sparks stated that he made inquiries and found that two people had received shock and had been restored in this manner. The first shock was from an arc lighting machine at about 2,500 volts pressure (about 15 years ago), and the man was insensible. They had tried to resuscitate him, and sent for a doctor, who after some time said the man was dead, and it was no use going on. The person in question, however, was very well liked, and his fellow comrades, in spite of what the doctor had said, continued to try to resuscitate him. In this they were eventually successful, and the man is alive to-day. This happened twelve years ago. The other case was at 2,000 volts alternating current, and there again artificial respiration was resorted to, and the person was revived.

Mr. H. Faraday Proctor was then called on behalf of the Incorporated Municipal Electrical Association, the Association of Municipal Corporations, and the Bristol Chamber of Commerce, and dealt first of all with the question of voltage. He said he had had experience of all pressures from 2,000 volts downwards for nineteen years, and in no case had he experienced any accident at 250 volts or below. The previous evening he had communicated with a number of the most important cities in Great Britain on this question, including Liverpool, Manchester, Bristol, Leeds, Birmingham, Sheffield, Bradford, Nottingham, Edinburgh, and Glasgow, and in none of these cases had the engineers experienced an accident from electric shock at 250 volts or less which caused loss of life or permanent injury. In one of these places only had there been an accident, to the knowledge of the engineer, on consumer's premises, and in this case he understood that it took place in connection with temporary work. His own view was that there was nothing to be gained by having regulations for these lower pressures. Where there had been accidents such as that mentioned at Fulham Baths and elsewhere, the accident would have occurred notwithstanding any regulations as were now proposed, or any regulations that could possibly be framed. In electricity works where the men employed were all trained and knew of the risks they incurred, he thought a little red paint was a very much better preventative than regulations. With regard to Regulation 30, he thought it would be a great injustice to the electrical industry generally if this "corpse revival" notice was to be put up in all premises where electricity was used at low pressure. If the Home Office would go so far as

Digitized by Google

to make similar notices compulsory on all premises where gas was employed, *i.e.*, in every dwelling-house throughout the kingdom, he would not have so much objection to their application on premises where electricity was used, because they would then be treated with that amount of consideration which they deserved. In fact, they would become equivalent to putting a poison label on a medicine bottle, that is, very little notice would be taken of them.

In cross-examination by Mr. Gray, Mr. Faraday Proctor admitted that if the Fulham Baths conduit had been properly earthed there would not have been so much risk, but no regulation could guard against careless work. Generally speaking, he regarded the rules as more or less harmless for the objects they were intended to effect.

Mr. C. Fleetwood Pritchard next spoke on behalf of the Incorporated Municipal Electrical Association and the Association of Municipal Corporations, which he said represented practically every local authority of importance throughout the kingdom, whose combined capital expenditure upon electricity works was about 4½ million pounds. The Home Office had powers under Section 17 of the Factory and Workshops Act to prosecute any occupier whose machinery was not safe for the workpeople, and as they had never put these into force, in regard to generating stations, he asked if it was not fair to assume that in the opinion of the Home Office generating stations as a whole were safe. The only other conclusion to be drawn was that the Home Office had not done its duty, and this he would not suggest. If any regulations at all were to be enforced, they should be of a tentative character, rather than of a fixed nature. The danger from 250 volts or less was not exceptionally great, nor was it greater than in any factory employing steam or any other form of power. On the question of arbitration, he agreed substantially with the arguments of Mr. Vesey Knox, but did not like the form suggested. His clients thought it was just as important to have the right of appeal to arbitration for works constructed after the rules came into force, as it was in connection with works constructed before. Neither did he like the limit of £100, because an important question of principle might arise involving a much less sum. In this same connection he asked for the inclusion of Rule 55 of the Coal Mines Regulations, which he thought would meet the difficulty of Mr. Gray, who, in principle, agreed that in some way existing work should be protected against undue prosecution, by a certificate from the Secretary of State. The regulation in question read as follows:—"Any of the foregoing requirements shall not apply in any case in which exemption is obtained from the Secretary of State, on the ground either of emergency or special circumstances, on such conditions as the Secretary of State may prescribe." On Regulation 29, which deals with the appointment of the "authorised person," Mr. Pritchard argued that it was unnecessary to allow either the contractor or the occupier, or both, to appoint the authorised person, as this might lead to a contractor's man being under the control of the occupier, while the contractor would be responsible for the work that was being done. Subject to these points being made, and adopting the previous arguments on behalf of the objectors, Mr. Pritchard said his clients were quite willing to give the regulations a fair trial, although they did not regard them as perfection.

Mr. Gutteridge, on behalf of the London County Council, said that this body occupied a somewhat peculiar position in relation to this inquiry. The Council had a large tramway generating station and two smaller generating stations, and about twenty tramway sub-stations. With regard to the latter the position appeared to him to be that they were not under the Factory Acts at all, as they did not come within the definition of "electrical stations" in the Factory Acts, but certain workshops connected with the sub-stations might come within the purview of the Acts. The County Council was also affected in that they were, under the Electric Lighting Acts, the inspecting authority in the county of London. He supported the arguments in favour of preventing anybody prosecuting, and, on the question of voltage, felt, on behalf of the ratepayers, that in the case of a small manufacturer, the limits of voltage stipulated in the regulations would press rather hardly. There was no other set of regulations published by the Home Office which were similar to these, either as to length or as to abstruseness.

Mr. C. W. Downing, on behalf of the Barry Railway Co., asked the Commissioner, in considering these regulations in their application to docks, to take into consideration the heavy penalties already inflicted by the Factory Acts, and also the fact that docks are under regulations of the Board of Trade and also other regulations made by the Home Office. He supported the arguments in favour of exempting docks from these regulations altogether, and if in this he was unsuccessful, then he desired to call the attention of the Commissioner to Section 79 of the Factory Act of 1901, which laid it down that regulations must be reasonable, practicable, and deal with the necessities of the case. As an illustration he referred to Regulation 26, dealing with adequate lighting, and in respect of electric lighting stations, urged that it had never been suggested that an accident had occurred through want of lighting. He asked that the evidence should be placed against each regulation, and that if the necessities of the case did not demand it, then that regulation should not be allowed. The regulations should be clear and specific, and there should be no ambiguity.

Mr. W. B. Woodhouse, on behalf of the Yorkshire Electric Power Co., the Leeds Chamber of Commerce, and others, said that so far as the power company which he represented was concerned, he was in a somewhat different position to those represented by Mr. Merz, whose undertakings were more or less established. The Yorkshire Power Co., like many similar companies in the country, were doing pioneer work, and had practically only just started. The difficulty of coming to any real agreement as to any regulations to suit every type of apparatus or switchgear, he thought, was apparent in the informal discussions which had taken place between the Committee of Objectors and the Home Office. The Board of Trade regulations under which they now worked did not prevent the evolution of new types of apparatus, but he contended that the Home Office Regulations would undoubtedly have this effect, and any regulations that were to be imposed should enter into as little detail as possible. He claimed that there were far too many regulations in the proposed code, and as an example suggested that the regulations relating to fencing a portion of a generating station where the switchboard was, might give the impression to the workers that the unfenced portion of the station was not dangerous, whereas it would contain all sorts of apparatus equally, if not more, dangerous than the switchboard. Dealing with the 250-volt limit, he compared the risk of danger under this as being similar to the possibility of drowning in 6 in. of water, and the imposition of regulations in respect of this danger was equivalent to putting a lifebelt at every roadside puddle. The Home Office had not brought to light any danger from electricity which had not been thoroughly realised for years, and there was not sufficient justification for the number of these regulations. If he were selling any other form of power than electricity, he would have taken advantage of the opportunity of securing a copy of the original regulations, if they had passed in that form, and labelled them "33 Reasons Why You Should Not Use Electricity," and this, he thought, would have been one of the finest arguments in favour of any other form of power.

Mr. Sidney Morse, on behalf of the British Electric Federation and others, reminded Mr. Swinburne of the great difficulty under which the electrical industry has laboured since its commencement. He referred to the retarding effect of the Electric Lighting Act of 1882, an effect which had led up to the Act of 1888; to the outcry with regard to uninsulated returns for tramway purposes and to the agitation on the part of gas and water companies on the question of electrolysis. Experience had proved that all these fears had been unfounded, and he ventured to suggest that the fears of the Home Office as to the safety of the workers in electrical stations had, by experience, been proved equally unfounded. There had only been one death in a year in all the factories inspected by the Home Office, and this, in 20 years' experience, he urged, was not sufficient to justify these regulations. He considered that the Home Office had gone unnecessarily out of its way to declare electricity a dangerous trade, for the impossibility of doing away with accidents was commented upon in the report of the Coal Mines Committee, which stated that it was not anticipated the set of regulations drawn up in respect of mines would prevent accidents, and that, indeed, electrical accidents might even increase. Even that committee thought the large number of regulations imposed by them might cause alarm. He agreed with the previous speeches on the question of voltage, and that the dangers of electricity under 250 volts were no more than the ordinary dangers in everyday life. He also agreed that there must be an appeal, to which, so far as he could understand, the only objection was one of expense.

Mr. Gray said that this was not so. The feeling of the Home Office was that the introduction of an appeal would tend to take the control of these matters out of the hands of the Home Office altogether, which was not desirable, and would render the administration of the regulations almost impossible. Up to now there was no power of appeal in respect of any set of regulations issued, except two cases, namely, the earthenware and the china transfer rules, but in these cases the appeal was not in respect of the decision of the Home Office, but in respect of a difference between local authorities and the owner. The appeal in the case of coal mines was not introduced by the committee, but already existed in the original Act.

Mr. Morse said that the question really only came to one of getting the proper staff to carry out the regulations.

Mr. A. M. Sillar, representing a number of factory owners, stated that he agreed with all the arguments put forward by Lord Robert Cecil on behalf of the London Electric Lighting Companies.

Mr. A. B. Cane said that on the question of the *flat*, the Home Office was unable to come to any agreement with the objectors which would effect this object, although both sides were agreed as to the necessity of there being a prosecution only by the Home Office. The matter was therefore left in the hands of the Commissioner, as the Home Office preferred not to take upon themselves the burden of suggesting a way out of the difficulty. With regard to the question of the sub-stations mentioned by Mr. Sparks, in which the size was limited by a previous order, but which would not comply with the proposed regulations, here again the objectors had the sympathy of the Home Office, and the objectors thought that some definite clause might be introduced to exempt them. Rule 56 of the Coal

Digitized by Google

Mines Regulations would effect this, with drafting amendments to suit this particular case, and he suggested the following:—"Regulations 25 and 31 to 33 shall not apply to any system of sub-stations or transforming chambers constructed in accordance with plans prescribed or approved by the Board of Trade, or to any extensions of such system of similar construction."

Mr. Gray then commenced his speech on behalf of the Home Office in reply to the objectors. He first acknowledged the fair and frank assistance which the Home Office had received from the objectors in committee, but expressed his disappointment that after the conference in committee there should have been objections raised to the principle of, at any rate, certain of the regulations. Having gone into the details of all the regulations in committee, he had rather been under the impression that the questions of principle raised at the commencement of the proceedings had been abandoned. The great arguments against the rules generally, and also upon the question of voltage in particular, was that there had been no serious accidents arising from the use of electricity; in other words, to justify rules it was necessary that an industry must first pay a heavy toll of human life. The evidence had all been "I know of no accident"; but this was not the proper attitude, in his opinion, for any objector to take in considering the question of whether rules were or were not to be enforced. He claimed that there had been no evidence of any kind, or in any substantial form, of any oppressiveness of these regulations except in quite general terms. The Home Office had had, from the commencement, at heart the interests of the industry, and it was by reason of this that many of the modifications had been made, because it was desired to have the simplest way of properly protecting workmen not only as regards life, but also as regards injury to health or limb. He thought he was right in saying that amendments had been accepted in practically every single regulation as they appeared in the original draft. On the question of voltage, whether there was one or one hundred accidents was not the criteria; it was a question of common sense. The evidence of Mr. Proctor on this point was merely that there had been no fatal accident or accidents involving serious injury, but all the witnesses had admitted the possibility of danger in some degree from a man receiving a shock, which might only be sufficient to startle him, but at the same time involve dangerous consequences from falling off platforms and such like. It was accidental injuries which had to be guarded against. Machinery was not fenced to prevent a man getting into the wheels deliberately, but to prevent him getting there accidentally. Some objections had been raised to the industry being certified a dangerous trade, but it was beyond their province to discuss this, for the Home Secretary had so certified the industry under Section 79 of the Factory Act, and, with all respect, that point did not come within the purview either of the Commissioner or of the objectors. With regard to the degree of danger between alternating current and continuous current, all the evidence was in his favour, for the objectors had brought no evidence on this point, and he thought there was no alternative to the Commissioner but to report that, *qua* limit, alternating current should be lower than continuous current. A good deal had been made of Mr Ram's report for 1906, in which, it was stated, reference was made to only one instance of a fatal accident at less than 250 volts. But this was the voltage of the system, and did not come into the matter at all. The question which was really of importance was the voltage at which the shock was received, and a glance down another column of the table in question showed that there were several deaths from shocks at less than 250 volts, and the point which was in his favour was that in none of these cases could the voltage at which the shock was received have been higher, but it could have been less.

Mr. Sidney Morse pointed out that the exemption related to the voltage of the system, and it was to the exemption that the objection was made.

Mr. Gray, continuing, said that from 1902 to 1906 Mr. Ram's report showed a total of 84 fatal accidents, of which 24 were at pressures within the limit of low pressure under these regulations.

Mr. Swinburne said he had a little difficulty in understanding what was meant in these reports by the expression "probable voltage of shock."

Mr. Ram stated that, for instance, in two-phase systems where the voltage of the system was 280, the probable voltage of the shock would be about 200 volts between one phase and earth. A single alternating-current system of 200 volts would probably give the same.

Mr. Gray said his object was to show that it did not matter in the least what the voltage of the system was. But he even did not rely upon this. The real point was, did these regulations, or any of them, impose an oppressive burden upon the industry? He ventured to say that there was not one tittle of evidence, beyond general statements, put before the Commissioner on this point. His argument in this respect was strengthened by the fact that the inquiry had gone on for the most part by way of Committee, rather than by public inquiry. A great deal also had been made of the 250-volt limit in the Board of Trade rules. These did not apply, however, to workmen at all, but only to the consumer, and were directed practically to a class of consumer using electricity mainly for electric light, in which every part of the installation could be arranged so that there was no danger from shock. Further, the Board of Trade rules did not apply to factories where there were motors and bare conductors, and, also, the rules in question prohibited voltages above 250. Therefore they were not comparable in any way with the proposed regulations of the Home Office. With regard to the objections that 100-volt continuous-current systems went free, if the objectors desired it, the Home Office would make 100-volts continuous current come within the regulations. With regard to whether rules should be retrospective or not, the suggestion that existing works should not be affected by them, was an impossible position. If it was necessary to have regulations for future work, it was essential that they should be also applicable to present work, unless there were special circumstances which would give them an exemption, and a good deal had been done in this latter direction by the modifications which had been accepted by the Home Office. As regards old stations under Rule 17, the dimensions had been dropped out, and slightly modified as regards new work. The suggestion of the objectors that no works should be prosecuted for non-compliance with the rules, until there had been a certificate from the Secretary of State, would make the regulations nearly a dead letter, for it put upon the Home Office the duty of reporting that a particular works did not comply with the regulations before alteration could be compelled to be made. Another point to be noted in connection with the general opposition to the regulations was that all the evidence submitted was from the electric power station point of view, and there had been no evidence from a factory, not being an electrical undertaking. (This remark called forth several protests from gentlemen representing factories, who stated that their evidence was intended to refer to factories as well as to their electric supply undertakings.) Dealing with the question of the appeal from the decision of the factory inspector, Mr. Gray pointed out that in the case of the fire regulations, which had been mentioned so many times, the appeal was between the local authority and the occupier, and did not concern the Home Office. In fact, the general power of appeal to arbitration had been deliberately left out of the Factory Acts, because it was regarded as unwieldy.

THURSDAY, MARCH 26TH.—TENTH DAY.

Mr. Gray, continuing his speech, said that in order to meet the objections to Exemption 5 in connection with which the objectors desired that the whole onus should be put upon the Home Office to show that a works did not comply with the regulations, the Home Office would be willing to add the following words: "And the Secretary of State may, by order, direct that any class of special conditions defined in the order shall be deemed for the purpose of all or any of the requirements of these regulations adequately to prevent danger." This would prevent the Home Office from being placed in the anomalous position of being unable to take any action until it had certified.

Mr. A. B. Cane asked for an assurance that such an order would be granted in the case of the special sub-stations of the County of London Electric Supply Company.

Mr. Gray said that he could give this assurance.

Continuing, Mr. Gray referred to Regulation 34, which had been substituted for Regulation 28. The latter had originally provided for inspections and tests, but to meet the objectors, the Home Office had dropped the "tests" and although, as a matter of fact, he had agreed to abandon the regulation as it now stood, relating only to inspections, he still thought there should be an inspection in the interests of the industry, and in his opinion it was the duty of the Commissioner to consider whether this regulation should not remain.

Mr. Vesey Knox, Mr. Cane, and Mr. Morse all protested on this point, as they said, having been assured that Regulation 34 would be dropped, they had not argued it.

Mr. Swinburne said that the Home Office was practically asking him to reinstate a regulation which the objectors thought had been dropped, and he was really obliged to consider everything.

Mr. Gray next dealt with the question of prosecution for non compliance with the regulations. Whilst agreeing with the principle of this, he said he had some doubt as to whether it would not be *ultra vires* to put in a proviso that nobody but the Home Office should prosecute, because it might be taking away the rights of some other persons or some other department which now existed, to prosecute. The only way out of the difficulty he could suggest was to leave it for the Commissioner to draw attention to the point in his report, and it might be necessary to take the opinion of the law officers of the Crown in respect of it. To meet a point raised by Mr. Pritchard, he agreed to have inserted in the regulations a definition of "public supply." Dealing with Mr. Trotter's evidence, some doubt seemed to exist in the minds of the objectors as to whether the alteration in the Board of Trade regulations which he suggested would be carried out. The Home Office had not yet had any further information from Mr. Trotter, but he had no doubt that as it was the desire of both departments to have no overlapping, they might rest assured on this point.

Mr. Vesey Knox pointed out that there were several Board

Digitized by Google

of Trade regulations which should, at any rate be limited; for instance, Rule 6. This dealt with maintenance of insulation, and Rule 9 with transformers, both of which were dealt with in the Home Office regulations. Rule 8, also, which related to circuit breakers for high-pressure mains. The view of his clients, however, was that all these should come under the control of the Board of Trade, so far as they were not on a factory.

Mr. SWINBURNE mentioned that there were cases in which apparently the Board of Trade was overlapping in factories, but was not doing so in reality. The Board of Trade, on behalf of the public, might have to go inside and suggest alterations because of the danger to the public, and not so much from the point of view of the workmen. He would, however, go into this question thoroughly and report as to which regulations he thought ought to be limited.

Mr. GRAY, on Exemption 2, recalled that Mr. Vesey Knox required some provision with regard to docks; in fact, he wanted docks to be exempted. If this was so, he did not know what Exemption 2 would mean, and he thought that if docks were exempted from Regulations 7, 8, 9, and 10, there was no need for any other regulations to be included in this exemption, so far as docks were concerned.

A long discussion here took place between Mr. Gray and Counsel for the objectors on the question of the appeal to arbitration, the point in dispute being as to whether under the Factory Acts the right of appeal to arbitration in individual cases had been substituted by inquiries such as the present one. This was the contention of the Home Office, and the point was finally left to the Commissioner. At the conclusion of the discussion,

Mr. GRAY said he thought that none of the speeches had carried the matter any further, and the fact remained that the objectors were asking the Commissioner to initiate an entirely new practice under the proposed rules, which did not exist under any other rules issued by the Home Office. No suggestion had been made that the present administration with regard to other regulations was in any way different as to make arbitration necessary. He submitted that the suggestion was unworkable and unprecedented. As to the date when these regulations should come into force, he suggested January 1st, 1909, with a provision that a year should be given to enable occupiers to comply with the necessary requirements of the regulations.

In conclusion, he expressed the appreciation of the Home Office at the manner in which Mr. Swinburne had conducted the inquiry, and at his forbearance in listening to a number of elementary matters which had been discussed quite solemnly, but which it had been necessary to do from the nature of the inquiry.

Mr. VESEY KNOX associated himself with the expression of the appreciation on behalf of the objectors.

Mr. SWINBURNE said he thought matters had been simplified and facilitated to a very great extent by the very successful method which had been adopted of discussing the regulations in committee.

The inquiry then terminated.

We give below the complete definitions, exemptions, and regulations as they were left at the conclusion of the inquiry :—

DEFINITIONS.

"*Pressure*" means the difference of electrical potential between any two conductors, or between a conductor and earth, as read by a hot wire or electrostatic voltmeter.

"*Low pressure*" means a pressure normally not exceeding 250 volts.

"*Medium pressure*" means a pressure normally above 250 volts, but not exceeding 650 volts.

"*High pressure*" means a pressure normally above 650 volts, but not exceeding 3,000 volts.

"*Extra-high pressure*" means a pressure normally exceeding 3,000 volts.

"*System*" means an electrical system in which all the conductors and apparatus are electrically connected to a common source of electromotive force.

"*Conductor*" means an electrical conductor arranged to be electrically connected to a system.

"*Apparatus*" means electrical apparatus, and includes all apparatus, machines, and fittings in which conductors are used, or of which they form a part.

[Definition of "Cable" deleted.]

"*Circuit*" means an electrical circuit forming a system or branch of a system.

"*Insulating stand*" means a floor, platform, stand, or mat
"*Insulating screen*" means a screen
"*Insulating boots*" means boots
"*Insulating gloves*" means gloves
} of such size, quality, and construction, according to the circumstances of the use thereof, that a person is thereby adequately protected from danger.

"*Covered with insulating material*" means adequately covered with insulating material of such quality and thickness that there is no danger.

"*Bare*" means not covered with insulating material.

"*Live*" means electrically charged.

"*Dead*" means at, or about, zero potential, and disconnected from any live system.

"*Earthed*" means connected to the general mass of earth in such manner as will ensure at all times an immediate discharge of electrical energy without danger.

"*Sub-station*" means any premises, or that part of any premises, in which electrical energy is transformed or converted, and which are large enough for a person to enter after the apparatus is in position.

"*Switchboard*" means the collection of switches, or fuses, conductors, and other apparatus in connection therewith, used for the purpose of controlling the current or pressure in any system or part of a system.

"*Switchboard passage-way*" means any passage-way or compartment large enough for a person to enter, and used in connection with a switchboard when live.

"*Authorised person*" means a person employed, appointed, or selected by the occupier, or by a contractor or contractors for the time being under contract with the occupier, to carry out certain duties incidental to the generation, transformation, distribution, or use of electrical energy, and competent to carry out those duties.

"*Danger*" means danger to health or danger to life or limb from shock, burn, or other injury to persons employed, or from fire, attendant upon the generation, transformation, distribution, or use of electrical energy.

"*Public Supply*" means the Supply of Electrical Energy by any Local Authority, Company, or Person, authorised by Act of Parliament or Provisional Order confirmed by Parliament or by License or Order of the Board of Trade or otherwise under Board of Trade Regulations, to give a supply of Electrical Energy.

EXEMPTIONS.

1. Nothing in these Regulations shall apply to any system the normal working pressure of which does not exceed 150 volts continuous or 65 volts alternating.

2. Nothing in Regulations 7, 8, 9, and 10 shall apply in electrical stations to any circuit or conductor used for conveying electrical energy for public supply or for traction under license or other statutory powers, or for railway purposes, or for docks constructed under statutory powers.

3. Nothing in Regulation 12 shall apply to any motor of a motor-generator or to any motor forming part of any electrical converter, regulator, or similar apparatus.

4. Nothing in these Regulations shall apply to any service lines or apparatus on the supply side of the consumer's terminals or to any chamber containing such service lines or apparatus where the supply is given from outside under Board of Trade Regulations; provided always that no live metal is exposed so that it may be touched.

5. If the occupier can show with regard to any requirement of these Regulations that the special conditions in his premises are such as adequately to prevent danger, that requirement shall be deemed to be satisfied; and the Secretary of State may by Order direct that any class of special conditions defined in the Order shall be deemed for the purposes of all or any of the requirements of these Regulations adequately to prevent danger.

6. Nothing in these Regulations shall apply to any process or apparatus used exclusively for electro-chemical or electro-thermal or testing or research purposes; provided such process be so worked and such apparatus so constructed and protected and such special precautions taken as may be necessary to prevent danger.

REGULATIONS.

1. All apparatus and conductors shall be sufficient in size and power for the work they are called upon to do, and so constructed, installed, protected, worked, and maintained as to prevent danger so far as is reasonably practicable.

2. All conductors shall either be covered with insulating material, and further efficiently protected where necessary, or they shall be so placed and safeguarded as to prevent danger so far as is reasonably practicable.

3. Every switch, circuit-breaker, and isolating link shall be :—(*a*) so constructed, placed, or protected as to prevent danger, (*b*) so constructed and adjusted as accurately to make and to maintain good contact, (*c*) provided with an efficient handle or other means of working, insulated from the system, and so arranged that the hand cannot inadvertently touch live metal, (*d*) so constructed or arranged that it cannot accidentally fall or move into contact when left out of contact.

4. Every switch intended to be used for breaking a circuit and every circuit-breaker shall be so constructed that it cannot with proper care be left in partial contact. Every switch intended to be used for breaking a circuit and every circuit-breaker shall be so constructed that an arc cannot accidentally be maintained.

5. Every fuse and automatic circuit-breaker used instead thereof shall be so constructed and arranged as effectively to interrupt the current before it so exceeds the working rate as to involve danger. It shall be of such construction or be so guarded or placed as to prevent danger from over-heating, or from arcing or the scattering of hot metal or other substance when it comes into operation. Every fuse shall be either

Digitized by Google

of such construction or so protected by a switch that the fusible metal may be readily renewed without danger.

6. Every electrical joint and connection shall be of proper construction as regards conductivity, insulation, mechanical strength, and protection.

7. Efficient means, suitably located, shall be provided for cutting off all pressure from every part of a system as may be necessary to prevent danger.

8. Efficient means suitably located shall be provided for protecting from excess of current every part of a system as may be necessary to prevent danger.

9. Where one of the conductors of a system is connected to earth, no single pole switch other than a link for testing purposes or a switch for use in controlling a generator shall be placed in such conductor or any branch thereof.

10. Where one of the main conductors of a system is bare and uninsulated, such as a bare return of a concentric system, no switch, fuse, or circuit-breaker shall be placed in that conductor, or in any conductor connected thereto, and the said conductor shall be earthed.

11. Every motor, converter, and transformer shall be protected by efficient means suitably placed, and so connected that all pressure may thereby be cut off therefrom and from any apparatus in connection therewith, provided, however, that where one point of the system is connected to earth, there shall be no obligation to disconnect on that side of the system which is connected to earth.

12. Every electrical motor shall be controlled by an efficient switch or switches for starting and stopping, so placed as to be easily worked by the person in charge of the motor. Where necessary to prevent danger through the automatic re-starting of a motor every electrical motor or group of electrical motors shall be protected by a release which will automatically break the circuit if the current is interrupted, such release being suitably placed with regard to the danger to be prevented. Provided that no release shall be required for any motor which has an attendant constantly at the controller of such motor while at work. In every place in which machines are being driven by any electric motor, there shall be means at hand for either switching off the motor or stopping the machines.

13. Every flexible wire for portable apparatus shall be connected to the system either by efficient permanent joints or connections or by a properly constructed connector. Adequate precautions shall be taken against shock due to leakage or other cause in all places where the person handling the portable apparatus is not insulated from earth. In such places and in any place where the pressure exceeds low pressure, the portable apparatus and its flexible wire shall be controlled by efficient means suitably located, and capable of cutting off the pressure.

14. The general arrangement of switchboards shall so far as reasonably practicable be such that :—(*a*) All parts which may have to be adjusted or handled are readily accessible; (*b*) the course of every conductor may where necessary be readily traced; (*c*) conductors not arranged for connection to the same system are kept well apart and can where necessary be readily distinguished; (*d*) all bare conductors are so placed or protected as to prevent danger from accidental short circuit.

15. Every switchboard having bare conductors normally so exposed that they may be touched shall be located in an area or areas set apart for the purposes thereof or where necessary suitably fenced or enclosed. No person except an authorised person, or a person acting under his immediate supervision, shall for the purpose of carrying out his duties have access to any part of such area.

16. All apparatus appertaining to a switchboard and requiring handling shall so far as practicable be so placed or arranged as to be operated from the working platform of the switchboard, and all measuring instruments and indicators connected therewith shall, so far as practicable, be so placed as to be observed from the working platform. If such apparatus be worked or observed from any other place, adequate precautions shall be taken to prevent danger.

17. At the working platform of every switchboard and in every switchboard passage-way, if there be bare conductors exposed or arranged to be exposed when live so that they may be touched, there shall be a clear and unobstructed passage of ample width and height with a firm and even floor. Adequate means of access, free from danger, shall be provided for every switchboard passage-way. The following provisions shall apply to all such switchboard working platforms and passage-ways constructed after the [1st January, 1909] unless the bare conductors, whether overhead or at the sides of the passage-way, are otherwise adequately protected against danger by divisions or screens or other suitable means :—(*a*) Those constructed for low pressure and medium pressure switchboards shall have a clear height of not less than 7 feet, and a clear width measured from bare conductor of not less than 3 feet; (*b*) those constructed for high pressure and extra-high pressure switchboards other than operating desks or panels working solely at low pressure shall have a clear height of not less than 8 feet and a clear width measured from bare conductor of not less than 3 feet 6 inches; (*c*) bare conductor shall not be exposed on both sides of the switchboard passage-way unless either the clear width of the passage is in the case of low pressure and medium pressure not less than 4 feet 6 inches, and in the case of high pressure and extra-high pressure not less than 8 feet, in each case measured between bare conductors, or the conductors on one side are so guarded that they cannot be accidentally touched.

18. In every switchboard for high pressure or extra-high pressure : -(*a*) Every high pressure and extra-high pressure conductor within reach from the working platform or in any switchboard passage-way shall be so placed or protected as to prevent danger; (*b*) the metal cases of all instruments working at high pressure or extra high-pressure shall be either earthed or completely enclosed with insulating covers; (*c*) all metal handles of high pressure and extra-high pressure switches, and, where necessary to prevent danger, all metal gear for working the switches, shall be earthed; (*d*) every switchboard in continuous use shall either (i) be so arranged that the conductors thereof can be made dead in sections, and so separated by permanent or removable divisions or screens from all adjoining sections of which the conductors are live, that work on any section may be carried out without danger; or (ii) otherwise so arranged as to secure that the work may be carried out without danger.

19. All parts of generators, motors, transformers, or other similar apparatus, at high pressure or extra-high pressure, and within reach from any position in which any person employed may require to be, shall be, so far as reasonably practicable, so protected as to prevent danger.

20. Where a high pressure or extra-high pressure supply is transformed for use at a lower pressure, suitable provision shall be made to guard against danger by reason of the lower pressure system becoming accidentally charged above its normal pressure by leakage or contact from the higher pressure system.

21. Where necessary to prevent danger adequate precautions shall be taken either by earthing or by other suitable means to prevent any metal other than the conductors from becoming electrically charged.

22. Adequate precautions shall be taken to prevent any conductor or apparatus from being accidentally or inadvertently electrically charged when persons are working thereon.

23. Where necessary to prevent danger, insulating stands or screens shall be provided and kept permanently in position and shall be maintained in sound condition.

24. Portable insulating stands, screens, boots, gloves, or other suitable means shall be provided and used when necessary to prevent danger, and shall be periodically examined by an authorised person.

25. Adequate working space and means of access, free from danger, shall be provided for all apparatus that has to be worked or attended to by any person.

26. All those parts of premises in which apparatus is placed shall be adequately lighted to prevent danger.

27. All conductors and apparatus exposed to the weather, wet corrosion, inflammable surroundings or explosive atmosphere, or used in any process or for any special purpose other than for lighting or power, shall be so constructed or protected, and such special precautions shall be taken as may be necessary to prevent danger in view of such exposure or use.

[Regulation 28 deleted.]

29. No person except an authorised person, or a person acting under his immediate supervision, shall undertake any work where technical knowledge or experience is required in order to avoid danger. Where a contractor is employed, and the danger to be avoided is under his control, the contractor shall appoint the authorised person, but if the danger to be avoided is under the control of the occupier, the occupier shall appoint the authorised person.

30. Instructions as to the treatment of persons suffering from electric shock shall be affixed in all premises where electrical energy is used, other than for incandescent lighting at low pressure, and in all premises in which electrical energy is generated or transformed.

[Regulation 30 has not been modified, and is left to be dealt with by the Commissioner.]

31. Every sub-station shall be substantially constructed, and shall be so arranged that no person other than an authorised person can obtain access thereto otherwise than by the proper entrance, or can interfere with the apparatus or conductors therein from outside, and shall be provided with efficient means of ventilation and be kept dry.

32. Every sub-station shall be under the control of an authorised person, and none but an authorised person or a person acting under his immediate supervision shall enter any part thereof where there may be danger.

33. Every underground sub-station not otherwise easily and safely accessible shall be provided with adequate means of access by a door or trap-door, with a staircase or ladder securely fixed and so placed that no live part of any switchboard or any bare conductor shall be within reach of a person thereon; provided however that the means of access to such sub-station shall be by a doorway and staircase, (*a*) if any person is regularly employed therein, other than for inspection and cleaning, or (*b*) in any such sub-station not of ample dimensions, either if there is moving machinery therein, other than ventilating fans, or if there is extra-high pressure therein.

[To facilitate reference, the numbering has not been altered, notwithstanding the deletion of No. 28.]

THE ELECTRICAL EQUIPMENT OF A CORNISH TIN MINE

RECENTLY the Cornish Consolidated Tin Mines, Ltd., recognising the possibilities of Cornish tin-mining worked on modern lines, acquired among other propositions the South Crofty Mines, situated at Carn Brea. This mine has been worked for many years without giving any financial return. On coming under the control of the Cornish Consolidated Co., the whole

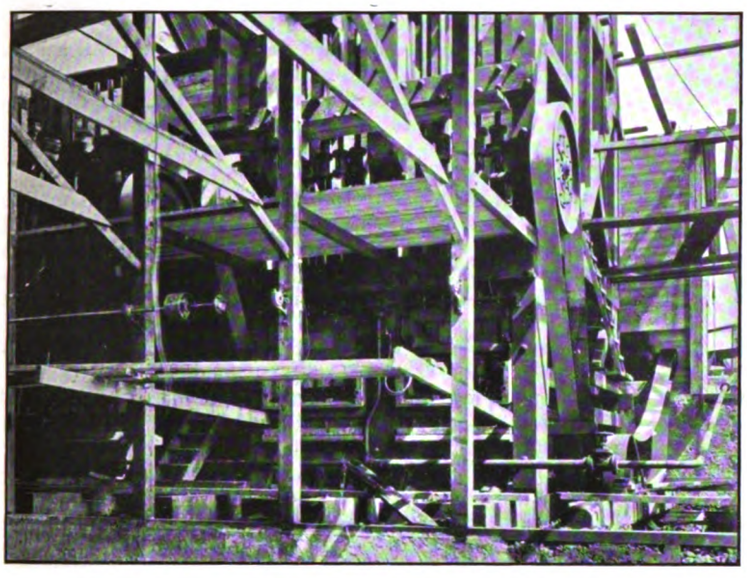

Fig. 1.—Group of Electrically-driven Californian Stamps.

of the underground and surface plant was remodelled, and what had been previously a financial failure will shortly prove to be the most favourable tin mine in Cornwall. The mill and dressing plant was originally operated by a single-cylinder, jet-condensing, balanced beam engine. The cost of operating this plant, neglecting capital cost, which was an unknown quantity, on 15,623 tons of ore treated annually was £1,884, or 2·4s. per ton.

When considering the reconstruction of the milling plant for operating, modern steam plant, suction gas, and electric driving were put forward, and after fully considering the relative costs and advantages, electric driving was decided on, the superior flexibility of motor drive for extensions at the mill and for operating the auxiliary machinery, the low capital cost, and the favourable working cost being the determining factors in favour of motors. Terms were arranged with the Urban Electric Supply Co., whose generating station adjoins the mine, for a supply of power at £6 per kw. of maximum demand, plus 0·45d. per unit, these figures to be rearranged when the maximum demand reaches 1,000 kw. The estimated cost of driving the mill and the auxiliary plant on the above basis being 1·8s. per ton, the actual cost works out at 1·08s. per ton of ore treated.

The ore previously won from the upper levels of this mine contained at least 30 per cent. of wolfram (tungsten), together with tin and arsenic, which could not at that date be satisfactorily separated. These levels were abandoned, and the lower levels which contained a less percentage of wolfram were worked, the wolfram being treated as an impurity, and a low price being accepted for the tin product.

With the advent of the new company, magnetic separation was resorted to, and the previously unsaleable complex ore separated into a tin and wolfram product, the tin commanding a much higher price, and the wolfram finding a ready market. The tin and wolfram product, which contains a heavy percentage of iron, after being calcined to remove the arsenic, is fed on to a 16 in. rubber belt, that travels between the pole-faces of three pairs of magnets, which are spaced apart and supported on a frame; as the belt carrying the product passes under the first pair of magnets, the iron product is drawn up on to a canvas transverse belt that removes the magnetised particles beyond the magnetic field, when the particles drop from the transverse belt into a bin. The product, that now contains tin and wolfram only, which are much less magnetic than the original product, is carried by the main belt under a second pair of magnets, having a stronger field than the first pair, where the wolfram is separated from the tin in a similar manner, the third pair of magnets removing the last trace of iron and wolfram from the tin product, which is now carried by the main belt into a bin and is ready for the smelter. This magnetic separation of minerals is simple and ingenious, and enables what was hitherto a complex, unsaleable product to be put on the market as clean tin and wolfram.

The mill, which at present consists of 40 heads, is arranged for driving in sections of 10 heads, as shown in Fig. 1, each section being driven by a 30 B.H.P. motor, arranged as in Fig. 2, only one section being interrupted should a motor fail or when the heads require attention, a spare armature being in readiness to ensure practically continuous running; whilst for future extensions, which will be commenced at an early

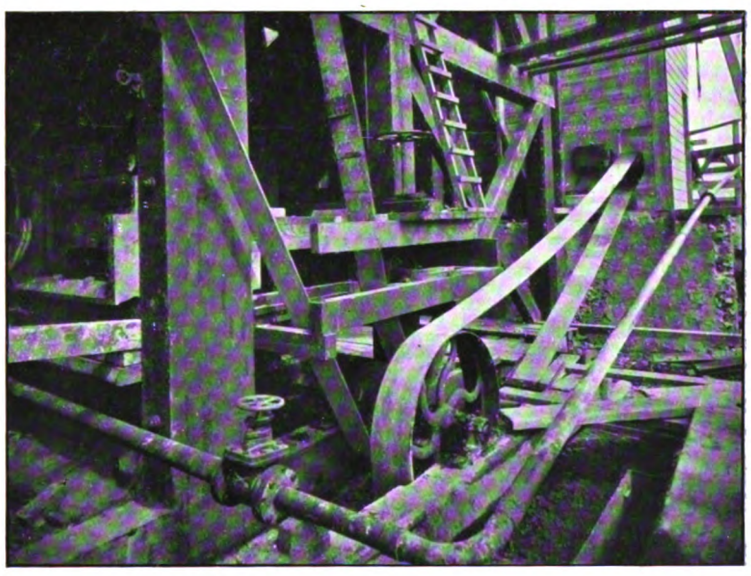

Fig. 2.—Arrangement of Motor Drive to Stamp Battery.

date, extra units can be easily installed. These extensions would have to be considered and arranged for with either of the alternative schemes. With no more ground space and a less number of attendants, the present mill deals with slightly more than twice the quantity treated by the old plant. This shows the advantage which has been obtained by the adoption of electrical working in the way of compactness.

E

The present installation of electrical apparatus consists of:—

Four	30 B.H.P	motors for mill drive.
Two	30 ,,	for Blake rock breakers (Fig. 3).
Two	20 ,,	for mill dressing plant.
One	20 ,,	for sorting table and dodge crusher.
One	20 ,,	for vertical pulverisers and calciners.
One	20 ,,	for tube mills.
One	20 ,,	for workshops.
One	17 ,,	for return water pump.
Two	5 ,,	for circulating pumps.
One motor generator		for magnetic separators.

The results obtained from electric driving at this mill are very satisfactory, the present cost being 1·08s. per

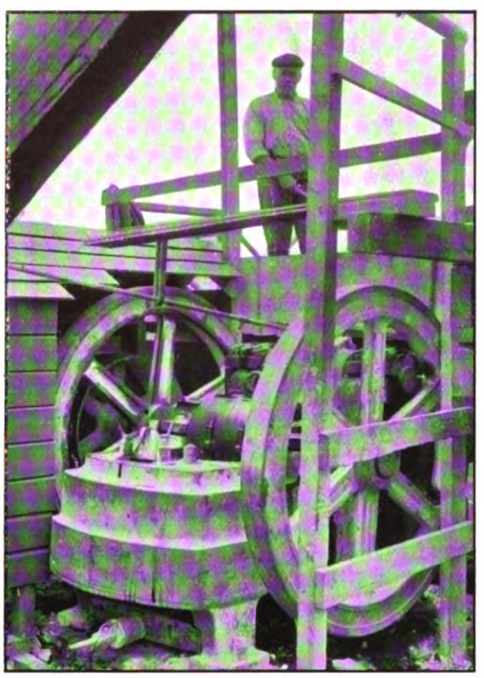

Fig. 3.—Rock Breaker driven by Electric Motor.

ton against 2·4s. per ton by the old method, the extreme flexibility for driving auxiliary plant and for extensions being not the least benefit obtained from the motor drive. All the electrical apparatus for this mine was supplied by the Brush Electrical Engineering Co., and installed by them to the directions of Mr. R. D. Gill, the consulting and resident electrical and mechanical engineer to the Cornish Consolidated Tin Mines.

CORRESPONDENCE

THE INSTITUTION OF CIVIL ENGINEERS.

To the Editor of Electrical Engineering.

Sir,—We have to-day received a communication from the Secretary of the Institution of Civil Engineers notifying us of a special general meeting of corporate members of the Institution to be held on Friday next, April 3rd.

(1) To authorise the Council to enter into an agreement for the sale of the Institution premises to H.M. Government; and

(2) To consider, and, if approved, to adopt the following alteration of the by-laws of the Institution:—

Section V., clause 6, to be altered by the omission of the words in brackets, and the addition of the words printed in italics.

Every new Member *shall, on admission to the Institution, pay a fee of twenty guineas, and every* Associate Member and Associate shall, on admission to the Institution, pay a fee of ten guineas, [but no payment, other than the increased annual subscription, shall be due from an Associate Member on his transfer to Membership,] *and every Associate Member on his transfer to Membership shall pay a fee of ten guineas. All such fees paid on transfer and one-half of the fees paid on election to Full Membership shall be treated as revenue unless otherwise directed by the Council.*

The letter further asked for a reply on a post-card enclosed expressing agreement with or dissent from the proposal before March 31st. We venture to think, Sir, that the proposals deserve more time for consideration and discussion amongst the members than can possibly be given under the circumstances indicated above, and that before members can express their opinions as asked for on the post-card they are entitled to further information.

The existing premises must presumably have been taken over by the Government at a fair price, and one fails at first sight to see the necessity for: (*a*) a special building fund, (*b*) additional revenue derived from transfer and entrance fees. Surely it is putting the cart before the horse to ask for an expression of opinion before the meeting, when, presumably, information will be given.

We venture further to think that the vote on the proposal to alter the by-laws should be taken, not at this meeting called at only a week's notice, but at a further meeting at a later date, when those members who may be prevented from attending on April 3rd have had an opportunity of considering the matter in the light of the printed report of the explanatory meeting.

Many members are disposed to think that the erection of the new buildings provides the opportunity for making the premises of much greater convenience to the general body of the members than has been the case in the past.

It is true that engineers have at the ordinary evening meetings opportunities of meeting brother engineers from the provinces and abroad, but it appears to us that the Institution might in a much greater degree than hitherto constitute a rallying point and meeting place for the members generally, and a place where informal discussions and conversations could be carried on.

The present building, stately as it is, does not contain a single cosy corner where two engineers can talk, much less smoke a friendly cigar together.

This is, however, neither the time nor the place for consideration of such details, and we merely beg the hospitality of your columns to enable us to make an appeal to fellow corporate members who may think with us to ask for further time in which to come to a decision and to communicate their views in writing to the Secretary and to attend the meeting on April 3rd.

We are, Sir, yours truly,

H. W. Handcock,
A. H. Dykes,
(*Associate Members of the Institution of Civil Engineers.*)

1 Victoria Street, S.W.,
March 30th, 1907.

THE FUTURE OF THE TELEPHONE SERVICE.

To the Editor of Electrical Engineering.

Sir,—Mr. A. R. Bennett is mistaken with regard to my relations with the National Telephone Company. My connection with that company is purely advisory, and I do not hold the "distinguished position" referred to, or any position in the company's organisation.

Mr. Bennett lives in a telephone world of his own, and presents the remarkable spectacle of a man who not only does not learn from the experience of others, but apparently does not learn from his own. The Glasgow municipal telephone system, the only one in which the experiment was tried on a serious scale, was run according to Mr. Bennett's theories, and it was such a hopeless failure that the Glasgow Corporation (who do not give up easily) were glad to sell it at a loss after a working life of a little over three years. No more convincing proof of the incorrectness of the theories could be desired.

There could be no surer way of making the telephone service of a large city both inefficient and unprofitable than to adopt a tariff having a low flat rate and a low message rate. Such a tariff positively encourages the users to make the service in-

Digitized by Google

efficient, and at the same time prevents the administration from making a profit.

The Imperial German Post Office has tried for years the experiment advocated by Mr. Bennett, has found it a failure, and is reverting to an exclusively measured rate tariff. In Berlin last January the Under-Secretary of State told me that his principal argument for the measured rate was that it would raise the efficiency of the service, which was being ruined by the excessive use of the flat-rate lines.

And that is my argument—more, my absolute conviction. The measured rate tariff, as well as encouraging the development of the telephone, improves the efficiency of the service. To the commercial community the important point is a highly efficient service, and the precise amount of the rate is a minor point. Any man in a large way of business will tell you the same thing—and that is the whole telephone question in a nutshell.

I am, &c.,

Herbert Laws Webb.

35 Old Queen Street, S.W., March 24th, 1908.

NO-VOLT RELEASES FOR POLYPHASE MOTORS.

To the Editor of Electrical Engineering.

Sir,—With regard to the recent controversy which has arisen with respect to the provision of no-volt release adjustments to polyphase motor switches, we desire to state that we have had considerable experience in this direction, especially in connection with high-tension switches, which we have now so far standardised that we can supply, as a thoroughly tested and commercial article, a form of starting gear for two- and three-phase motors fitted with no-volt release. This apparatus we can put forward with our fullest guarantee as to entirely satisfactory operation. You may remember that we sent you in the autumn of last year our large high-tension catalogue No. 67, which includes full details of the apparatus in question.

Yours faithfully,

The Union Electric Co., Ltd.

London, S.E., March 24th, 1908.

COMMERCIAL VEHICLES AT OLYMPIA

THE exhibition opened last Friday at Olympia is the second of the annual series of displays of "commercial" vehicles and motor-boats which the Society of Motor Manufacturers and Traders have organised since it was found necessary to arrange an independent show for these branches of the automobile industry distinct from that of vehicles for private use. Before noticing any particular stands, a few words may be said of the scope of the exhibits generally and the direction in which the different branches of industry represented by them has developed since the last show of its class a twelvemonth ago. The past year, so far as London especially is concerned, has seen not only a vast increase in the use of motor vans of all sizes for commercial purposes, but has witnessed the coming of the now ubiquitous motor-cab, and the putting upon the streets of the much-discussed but apparently successful "Electrobus." With regard to other types of motor-omnibus, strenuous attempts are being made to produce a more suitable design of vehicle than those hitherto in use, and experience has been gained in actual practise with more than one of the petrol-electric systems, which have been put forward as specially suitable for this class of work. The exhibition itself represents all these advances. Quite a large number of new motor-cabs are shown, and before the show is concluded it is hoped that an electric cab of modern design will make its appearance. An "Electrobus" of improved type, as compared with that shown last year, is exhibited, and two complete petrol-electric omnibuses are shown, as well as a finished chassis representing a system now at work in London. A few steam omnibuses appear, but the number of types of geared petrol omnibus exemplified is apparently less than last year. The use of accumulator-driven commercial vehicles other than omnibuses does not seem to be increasing in this country to anything like the same extent as in America, and we only find one stand in the exhibition devoted to the accumulator vehicle pure and simple, although, as we shall see, batteries form an important feature in one of the petrol-electric systems shown.

The stand of the Electric Vehicle Co., of 1 Earl Street, S.W., makes up for the fact of its being the sole representative of battery traction by the variety of its exhibits. Most prominent is the complete double-decked omnibus, built to order of the London Electrobus Co., which is of the improved chain-driven form described in Electrical Engineering, Vol. II., page 903. Five omnibuses of this type have already been delivered, and fifty more are on order. It will be remembered that they are considerably different in design from the first six electric omnibuses put on the road, in that two motors are used instead of one, and the live axle and differential gear formerly used has given place to an independent double reduction chain drive from each motor to one of the rear wheels. The motors are of the six-pole series wound type, each rated at 3·8 h.p., and each drives on to its own countershaft by a Morse silent chain. The controller is arranged for five speeds. In the first and second positions the motors are in series, with and without resistance respectively, and for the third and fourth speeds, parallel connection with and without the resistance is used. On the highest speed, which corresponds to a maximum of 12 miles per hour, the resistance is employed to weaken the fields. There are also three reverse speeds. The capacity of the batteries employed with these vehicles, some particulars of which were given in the article referred to, is sufficient for a mileage range of 45 miles, under service conditions, with the full complement of 34 passengers. We understand that 14 omnibuses of this type have been ordered by the Brighton and Hove Omnibus Co. Other vehicles on the stand include a chain-driven two-ton wagon, with two motors and a controller, giving four speeds forward and two reverse, for a range of 40 miles without changing batteries. A smaller delivery van, with a single motor and cardan shaft drive is also shown, as well as the electric carrier tricycle, which figured at the Agricultural Hall last week, and was referred to on page 464 of our last issue. This machine, which is of German origin, is driven by a single 3 h.p. Siemens-Schuckert motor, and is constructed to carry 3 cwt. The mileage range on one charge is said to be 30 miles, and the maximum speed attainable is ten miles per hour. It should be mentioned that the total weight, complete, but without load, is 7 cwt., of which 3 cwt. is formed by the battery. The battery is contained in a case under the box for the reception of the load, and is easily withdrawn by sliding out from the front. No connections whatever require to be made or broken, and the two metal rails upon which the battery slides are themselves the contacts. It is thought that these little vehicles will be found useful for such work as newspaper delivery, and other work where they can be connected to a charging board during the time when they are necessarily waiting for their load. Another new vehicle shown on the same stand is a two-seated passenger car, intended as an engineer's test and inspection car for tramway and electric supply work, and the example shown is fully equipped with electrical testing instruments. This handy little car weighs, complete, 17 cwt., of which 7½ cwt. is accounted for by the battery, and can travel up to 30 miles per hour, the mileage range is given as 80 to 100 miles. A vehicle which is suitable as an emergency repair wagon for tramway and other work, or for fire brigade purposes is also shown, and it is hoped that an example of the firm's "Electricab" will have crossed the Atlantic in time to be in the exhibition to-day or to-morrow. In order to show the possibility of touring in England on electric cars, a map is shown showing the various towns where charging facilities are available.

Turning to the petrol-electric omnibuses, which form perhaps the most interesting feature of the whole show, we find three systems represented, only one of which figured in last year's exhibition. A complete comparison of the systems which are actually available for omnibus work is not, however, possible, as one or two systems about which a good deal has been heard during the past year are unrepresented. In one of the systems shown batteries are employed, and under some conditions the transmission is mechanical, but in the other two, which represent the more general tendency, the transmission is at all times entirely electrical without batteries. All these are continuous-current systems.

Digitized by Google

The three-phase system which some designers uphold so strongly is not exemplified. It is interesting to note that in all three cases the motors drive the road wheels through worm gear.

One of the most interesting vehicles in the exhibition is the omnibus on Stand No. 55 of the DAIMLER MOTOR CO., near the centre of the hall. This vehicle is equipped on what is sometimes known as the "automixte" petrol-electric system, due originally to M. Henri Pieper, of Liège, in which an ordinary petrol engine is coupled to a machine which can act either as a dynamo or a motor according to circumstances, as it is also connected through a clutch and suitable reduction gear to the rear wheels. A small battery of accumulators also forms a feature of the system. When the car is at rest, or when the full power of the engine is not needed for propulsion, the dynamo is employed to charge the battery, but when extra torque is acquired for starting or hill climbing the battery drives the machine as a motor to assist the engine. Mechanical change speed gears are thus avoided, and it is claimed that a smaller engine may be employed, as only the average and not the maximum horse power required has to be considered. The vehicle is driven through an electro-magnetic clutch, and an electro-magnetic brake is also provided. The details of the system have been repeatedly described in the technical press, and a few light cars equipped on this principle are running in this country. The vehicle on the Daimler stand, however, is the first example of the system as applied to omnibus work which has been seen in England, although a similar vehicle is now in actual service in Paris. The equipment, so far as the arrangement of the electrical gear is concerned, is practically the same as that used on smaller cars except that in some of the omnibuses already built the arrangement of solenoid control of the throttle has been omitted in favour of hand regulation of the engine speed according to the indications of a voltmeter, and a positive clutch has been added between the engine and the dynamotor in order to facilitate running the vehicle on the electrical gear only in cases of necessity. Indeed, it was driven into the exhibition in this manner, as the running of petrol engines inside the building is not permitted. In this connection it may be remarked the placard on another stand stating that a certain other omnibus was the only vehicle to enter the hall under its own power is incorrect. Although it has not been exhibited before, this omnibus has been completed for more than a year, and has already been submitted to extensive road trials, so that it may be said to have emerged beyond the experimental stage. It came by road from the works, and will be driven back there at the conclusion of the show. The engine in the particular vehicle exhibited is a 4-cylinder Daimler engine of 120 mm. bore by 130 mm. stroke, with a rating of about 30 h.p., and the dynamotor, which is of the interpole type, was manufactured by Messrs. Dick Kerr & Co. The battery, which is placed under the driver's seat, is of the Tudor pattern, with Planté plates, and weighs 7 cwt., but on account of an absurd insurance regulation it has been removed since the vehicle was driven into the show. The size of engine and battery required naturally depends upon the nature of the service required, and the length and steepness of the hills to be encountered. It may be urged against the system that the battery is liable to run down when ascending a hill longer than that for which it is designed, and that this may prevent the vehicle being able to get up the hill, but all that is necessary in that case is to stop for a few minutes with the engine running and give the battery a short charge. There are several interesting points in the mechanical arrangement of the vehicle. The engine, dynamotor, and clutch are bolted up together and mounted by a three-point suspension in the main frame, which is connected to the front axle by springs in the usual way. The back part of this frame, however, upon which is mounted the gearing by which the back wheels are driven, is entirely unsprung. The body is mounted on an independent frame hinged to the under frame by the dash board, and supported by springs at the back. The under frame is made with as little bracing as possible, and has considerable sideways flexibility. The body, although free to move vertically on its springs, is constrained from lateral motion by horn blocks at the back. The drive from the magnetic clutch to the back wheels is through a longitudinal shaft driving a differential countershaft through a worm gear with a final enclosed spur reduction gear to each wheel.

The 30-33 h.p. petrol-electric chassis on Stand No. 36 of Messrs. J. & E. HALL, of Dartford, is exactly similar to that of the Hallford omnibus with petrol-electric equipment under the S. B. & S. syndicate and Stevens patents, which is now being run in actual service in London by Messrs. T. Tilling, Ltd., and which was fully described in an illustrated article in ELECTRICAL ENGINEERING, January 16th, page 83. The only difference lies in the design of the pressed steel frame. The working of this omnibus was referred to in the Paper read by Messrs. P. Frost Smith and W. A. Stevens recently before the Society of Road Traction Engineers, and reported in ELECTRICAL ENGINEERING, March 26th, page 475. The system falls under the class of petrol-electric systems, in which the transmission is at all times electrical and does not employ batteries. A 30 h.p. 4-cylinder engine drives a shunt-wound interpolar dynamo, which supplies current to two series-wound motors, one of which drives each back wheel through a specially-designed worm-gear. The use of a live back axle and a differential gear are thus entirely avoided. Provision is made for connecting the motor in series or parallel, but it is only in exceptional cases that the series notch is required. The control of the speed of the vehicle is effected almost entirely on the accelerator pedal and the field switch, and under ordinary conditions the main circuit is never broken, even at stopping. Before starting, unless the gradient is very steep, the controller lever is put into the parallel notch with the engine running slowly, and the generator field reduced. In order to start, the brakes are released, and the engine is accelerated by opening the throttle with the pedal, so that the voltage of the dynamo rises, the field switch is gradually moved over to raise the voltages as the vehicle gains speed. The running speed is then controlled by the throttle pedal, and to stop the throttle pedal is released, the dynamo field weakened, and the brake applied. The petrol consumption in actual service has been found to be 5¾ miles to the gallon, which, we are informed, is ¾ mile better than is obtained on the average by Messrs. Tilling for gear-driven omnibuses.

Another petrol-electric omnibus is exhibited by Messrs. GREENWOOD & BATLEY, of Leeds, on Stand No. 26. The actual chassis is the same as that exhibited on this firm's stand last year, but during the interval an engine of improved design has been fitted, and road trials to the extent of over 1,000 miles have been conducted with a three-ton load. The vehicle has been completed by the addition of an omnibus body, but no alteration has been made in the electrical equipment. A description of the chassis as it appeared last year was given in ELECTRICAL ENGINEERING, Vol. I., page 461, but it may be of interest to repeat the main features of the system. As in the last-mentioned system, the transmission is entirely electrical, and does not depend on accumulators. A continuous current compound-wound generator fitted with commutating poles is driven by the engine, which is of 35 h.p. This supplies current through a suitable controller to a specially designed motor provided with two armatures in one field casting. The double motor is mounted on trunnions near the centre of the frame, and is connected to the centre of the back axle by a stout tubular radius rod. Each armature drives its own half of the back axle through its own worm gear through a shaft provided with cardan joints. Thus no differential gear is required. The compounding of the dynamo is so arranged that the voltage shall hold up well till the engine begins to slow down, and it is necessary to perform the operation equivalent to changing gear. This is claimed to give better results than the falling characteristic obtained by the differential constant output employed in some systems in conjunction with series motors. The controller is actuated by a lever on the steering pillar, and is of the drum type with magnetic blow-out. The four forward speeds are by various arrangements of the motor armatures and fields in series and parallel, entirely without resistances. A good deal of the control is effected by variation of the engine speed, and for this purpose the usual throttle and ignition lever are provided above the steering wheel. One great advantage of this is that when speed has been attained on the level the speed of the engine can be reduced. Stopping and restarting are effected by a single foot-pedal, which actuates the main circuit breaker, and at the same time cuts out a large portion of the generator shunt field winding, thereby reducing the voltage. By this means a very smooth start is obtained, as the field has to build up after the pedal is released. The pedal is interlocked with the throttle so that the engine is slowed down when the main circuit is broken. The same pedal actuates, in its most forward position, the brakes on the motor shafts.

The trials on the road have shown a petrol consumption on a fairly hilly country route of six miles to the gallon. This was, however, with a new engine, which will show better economy when thoroughly run in. This figure, however, must not be taken as too much of a guide as to the probable consumption in ordinary service, with frequent starting and stopping. We understand that the result of experience on the road has been to show that a less number of controller notches would have been quite sufficient, as nearly all running can be done on the top speed, and the circuit breaker has been found to be almost unnecessary for ordinary manœuvring, although it is of the utmost use for sudden emergency stops. The ar-

Digitized by Google

rangement of not having the circuit breaker interlocked with the controller allows of changing the connections on a hill with much less loss of way than would be otherwise possible.

The motor-boat section contains little of electrical interest, and in the gallery which is devoted to accessories, no striking electrical novelty is shown. Messrs. Lodge Bros. & Co., of Birmingham, have a most effective show of electric igniters on Sir Oliver Lodge's system, of the excellence of which we can speak from personal experience, and exhibit forms both for motor cars and large gas engines. The leading particulars of the system were described in Electrical Engineering, Vol. II., page 798, in connection with the exhibition of private cars. The Bosch Magneto Co. show their latest form of ignition with electro-magnetic plug, as also described and illustrated last November in the article in question. A number of other well-known ignition devices are also represented.

THE CHICAGO DRAINAGE CANAL ELECTRIC POWER PLANT

THE accompanying illustrations give a few details relating to the hydro-electric power plant and equipment on the Chicago drainage canal at Lockport. This power transmission plant, owned and operated by the Sanitary District of Chicago, has a capacity of 16,000 kilowatts for the present development, with extensions provided for a power-station of an output of 32,000 horse-power. The drainage canal and power plant has cost over fifty million dollars. The canal extends a distance of 29 miles from the Chicago River to Lockport, Illinois, where it discharges into the Desplaines River, and the water flows finally through the Illinois River and empties into the Mississippi River, and thence at last into the Gulf of Mexico.

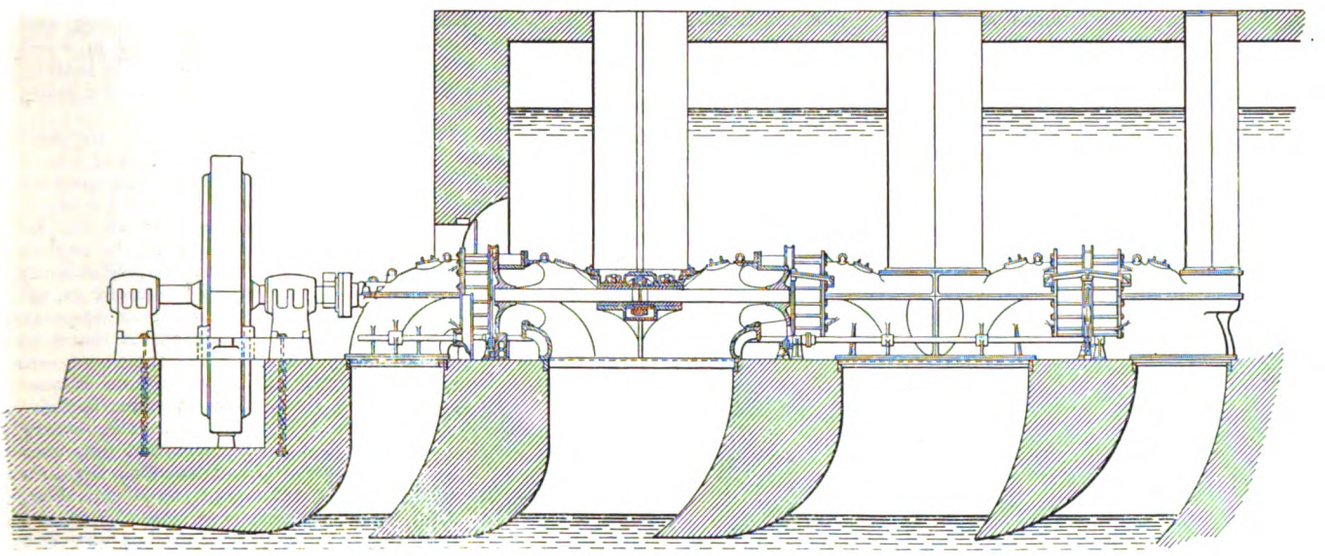

Fig. 1.—Sectional Sketch Showing Arrangement of Water Wheels.

The generating plant is situated at Lockport, about three miles from the city of Jolliet, where there is a regulation flow of more than a quarter of a million cubic feet of water per minute with a fall of twelve feet, the water being regulated by means of a "bear-trap" dam. The power-house is 385 ft. long and 47 ft high, with a width of 70 ft., and is of steel and concrete construction of plain but neat design. By extending the channel to a point about two miles further down from the point above-mentioned, instead of 12 ft. fall there is a fall of 34 ft., and here the power-house was placed, with a retaining wall for the channel 40 ft. high, bringing the water-level on the receiving side near the top of the power-house. The turbines have been installed in chambers at the floor-level, and work under a head of 34 ft. discharging through the chambers to the tailrace. The controlling works or movable-crest dam is on the east joining the power-house, and is designed to regulate the flow of water in the canal. The general arrangement of the plant is shown by the sectional sketch in Fig. 1.

The water-wheels, four in number, have been constructed by the Wellman-Seaver-Morgan Company, and a fifth unit will be installed in the spring. Each of the main turbines drives a three-phase alternator of 4,000 kilowatts capacity. There are two water-wheels of the same construction driving direct-current exciter dynamos, each of a capacity of 350 kilowatts. This plant was designed for eight alternators and turbines of 4,000 kilowatts each, and three exciter sets of 350 kilowatts each. The power-house is provided with a 40-ton electric overhead travelling crane of 35 ft. span, moving over the generator space along the north side of the power-house, which is 385 ft. long. The water-wheel for each unit is in a chamber adjoining, and has a capacity of 6,000 h.p. at a speed of 163 revolutions per

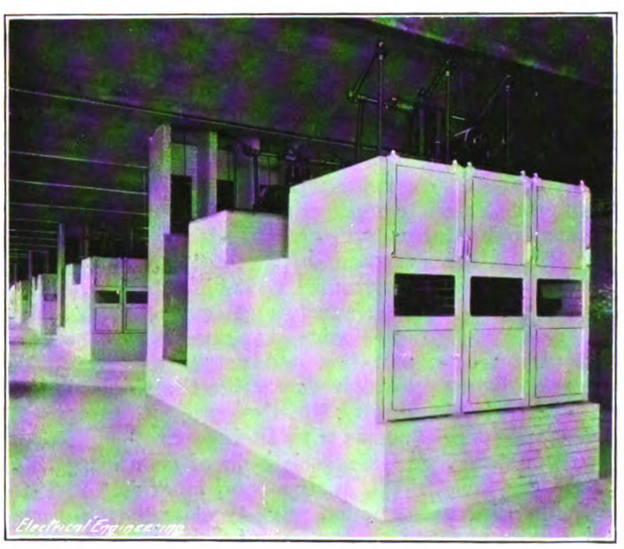

Fig. 2.—High-tension Switch Cells.

Digitized by Google

minute. The exciter sets have water-wheels of 600 h.p. each, each of these units being capable of supplying direct current sufficient for exciting the fields of several alternators.

The 4,000-kilowatt three-phase generators are of the Crocker-Wheeler type with revolving fields, and are wound for a pressure of 6,600 volts at 60 cycles.

The switchboards and step-up transformers, as well as the 'bus-bars, oil switches, and circuit-breakers, are on the south side of the power-station, and the transformers are on the main floor, with the 'bus-bars and oil switches on two galleries overhead. The arrangement of the cells containing the main oil switches is shown in Fig. 2, and the choking coils forming part of the protective equipment are shown in Fig. 3.

The transformer installation includes a dozen oil- and water-cooled step-up transformers of the General Electric single-phase type, each having a capacity of 1,333 kilowatts. There is an aluminium transmission line of 44,000 volts pressure, which conducts the current from the hydro-electric plant a distance of nearly 30 miles to a sub-station in Chicago, where the current is transformed down to 12,000 volts for local distribution. This transmission line consists of two circuits of three aluminium wires each mounted on insulators fastened to 60 ft. steel masts, the wires being spaced about 6 ft.

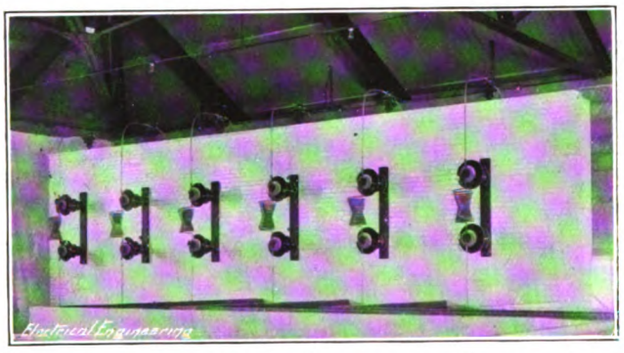

Fig. 3.—Choking Coils for Protection of Outgoing Lines.

apart. The masts or poles weigh about 2 tons each, and are of steel bridge construction, having a square base. Each mast is provided with two cross-arms, the top arm weighing 300 lb. and measuring 12 ft. in length, while the lower arm weighs double this amount and is 18 ft. long.

These steel masts or poles are placed 6 ft. in the ground, the holes being filled with concrete a half a foot above the ground, with rounded tops. The transmission wires on the lower arm are 47 ft. above the ground, mounted on insulators 12 in. high and 14 in. in diameter, tested to more than 100,000 volts. These high-tension insulators are provided with four petticoats or shells, and are mounted on a metal pin, the whole being designed for a horizontal strain of 5,000 lb. The poles are placed 350 ft. apart, and on the top of the poles an iron ground wire is carried the whole length of the line, and this conductor is expected to receive any lightning which may strike the transmission line, the iron poles carrying the discharge to the ground, being excellent conductors with their concrete supports.

The sub-station at Chicago is built of concrete 42 ft. high and 70 ft in width, with a total length of 124 ft. The sub-station is equipped with the usual step-down transformers and switch equipment, with motor-driven centrifugal pump for supplying cooling water to the transformers. The Sanitary District of Chicago has contracted with the municipality of Chicago for the supply of 7,000 kilowatts for the electrical department of the City. The Chicago sub-station will also supply current for the pump of the north channel, where 450 h.p. motors of the slow-speed type are used.

ELECTRIC OMNIBUSES IN PHILADELPHIA

A SERVICE of electric omnibuses was inaugurated last summer in the principal streets of Philadelphia by the Auto Transit Company. Some details of the generating station from which current is obtained for charging the batteries have already been given in Electrical Engineering (Vol. II., page 143). The principal feature of the generating plant is compactness, which is obtained by the use of de Laval turbines. The garage and accumulator charging and repairing shops which adjoin the generating station are described in a recent number of the *Electrical World* (New York), and it is of interest to compare the methods employed with the working of the London "Electrobus" (Electrical Engineering, Vol. II., page 905).

The room devoted to charging and repairing batteries is equipped for handling 80 batteries, and space is provided for 40 additional batteries. These are placed on timber stands and lead-covered cables are run to each stand. The negative leads are brought from the charging board located on the gallery at one end of the room, while the positive leads are all connected to a common busbar built up of copper strips and mounted on porcelain blocks, the whole being encased in wood boxing. The cables are carried along the floor under the battery stands and are thus out of the way when the batteries are being shifted.

The charging board is made up of 10 slate panels. On each panel is an ammeter and 12 three-point switches, each of which connects with a battery stand on the floor below. The operator is thus enabled to connect the battery to any desired busbar. The ammeter is arranged with a portable shunt which can be inserted in the clips of the switches in place of the switch blades used for closing the circuit so that the charging current of the battery may be observed, after which the shunt is removed and the switch closed, thus permitting one ammeter to serve the 12 switches and reducing the wiring on the board to the limit of simplicity. Three voltmeters are mounted on one end of the switchboard. Two methods of charging are in use. In the three-voltage scheme the potential on the three busbars is 90 volts, 100 volts, and 110 volts respectively. The battery is connected first to the 90-volt bus until the current decreases to a specified value, when the battery is switched on the 100-volt bus. The battery is finally connected to the 110-volt bus, where it remains until it is fully charged. In the second scheme, sufficient batteries are connected to one bus and one turbine is run under that load until the batteries are fully charged. Once started, little attention is necessary, and this is the quickest possible way of charging the batteries. In addition, the plan has the advantage of keeping the generators fully loaded, and is conducive to high efficiency.

The battery room is well ventilated, and has practically no exposed iron work. The battery-room floor is of asphalt. The battery trays are handled by a two-ton electric crane. The charged batteries are placed on trucks or cars which are pushed by hand in front of the battery ram. The latter is operated by a $\frac{1}{4}$-h.p. series-wound motor. The field coils of the motor are connected in parallel so as to give the motor sufficient torque. A friction nut is placed in the ram gearing to limit the thrust of the ram and prevent injury to either the ram or the battery. The equipment is capable of handling a battery every two minutes, and cranes, trucks and rams are provided in duplicate to guard against delay in case of breakdown. Distilled water is supplied from the condenser to a cedar tank located over the battery ram and the water is piped to convenient points in the battery room for use in the batteries. The storage batteries used are manufactured by the Electric Storage Battery Company, of Philadelphia. Each tray contains 42 cells of type 21 MV, connected permanently in series. The rated discharge of the battery is 70 amperes for four hours.

The method of handling the omnibuses as they come in is as follows:—The omnibus is run into a driveway until opposite the ram. In front of the ram is a battery truck or car with a fully charged battery. On the other side of the omnibus and directly opposite the ram an empty car is pushed. The battery in the omnibus is disconnected from circuit and an operator closes the switch which sets the ram in operation. In one operation the fully charged battery is pushed into the omnibus and the latter battery in turn pushes the exhausted battery out of the other side of the vehicle onto the car placed there to receive it. The connections to the new battery are quickly made, and in less time than it takes to relate it the omnibus continues on another trip. The batteries are lifted off the trucks by an overhead travelling crane, and taken to the required part of the battery room. In the repairing department there

Digitized by Google

is a small electrically-driven compressor for supplying air to the hydrogen blow-pipe used for lead burning.

The omnibuses, of which there are 25 in use, are of the double deck, London type, seating 34 passengers—18 on cross seats on top and 16 on side seats inside. The vehicles were built by the Commercial Truck Company of America, and the chassis is of similar design to that described in Electrical Engineering, Vol. I., p. 689, which was exhibited in one of the London automobile exhibitions, and experimented with the Electrobus Co. in London, although not finally adopted by them. Each wheel is equipped with a series motor of special design rated at 22 amperes, 90 volts, and 1,600 r.p.m. The motor is connected through a 14 to 1 double reduction gear to an internal gear attached to the hub casting of the wheel. The normal speed of the vehicle, fully loaded, is 12 miles an hour on a level street. The four motors are controlled by a revolving-cylinder controller having street-railway type of fingers. The combinations made are as follows: First notch, four motors in series without resistance; second notch, two front motors in series and in series with two rear motors in parallel with no resistance; third notch, motors in series parallel; fourth notch, motors in parallel with resistance; fifth notch, motors in parallel with no resistance. A bus under ordinary conditions and when fully loaded can travel 30 to 33 miles on a charge; but the trips are arranged so as to leave a safe margin to guard against the batteries running down while the bus is in regular service. Under the present arrangement the vehicles make two trips on one charge of battery, travelling a distance of 25 miles.

The vehicles are lighted by four 8-c.p. lamps, and two head and one tail lights of 4 candle-power are used to comply with the requirements of the automobile law. The brakes, which are operated by the foot, consist of hard-wood shoes pressing against a cast-steel surface on the hubs of the rear wheels. In addition, the controllers are designed to permit the motors to act as emergency brakes on the first notch with reversed connections in the event of the failure of the foot-brake. No circuit-breaker is used in the motor connections, but a cartridge fuse is inserted in each motor circuit. This fuse is large enough to permit sufficient current to pass for ordinary service and yet protect the motor.

The garage is designed to accommodate 50 vehicles. The omnibuses, when coming in for battery renewals, pass through the garage and give the attendants an opportunity for making close inspections and quick repairs. After the last trip a fresh battery is installed in the battery compartment under the body of the car, after which the vehicle is returned to the garage, where it is washed, inspected, and put in first-class order before being sent out the next morning. The repair shop is located in the same building with the garage, a room 40 ft. by 128 ft. being provided for that purpose. Particulars are not given as to costs of operation.

TELEPHONE AND TELEGRAPH CABLES

A PAPER was read by Mr. F. Tremain on the above subject at a meeting of the Newcastle Local Section of the Institution of Electrical Engineers on Monday, March 23rd. The Paper dealt exclusively with paper-insulated lead-sheathed cables, as other types have not to any large extent been altered in character for many years. The cost is governed in the case of large multiple cables by the quantity of copper required, although in small cables lead may become the governing factor.

For telegraph purposes pure and simple a single wire insulated with paper and surrounded by a screening tape of copper is in general use, although in cables which may be used interchangeably for telephone or telegraph purposes pairs of wires are used for both purposes, as will be explained later. In each case a copper wire, which varies in diameter from 25 mils for local purposes to 113 mils for trunk purposes, is insulated by means of paper carefully selected and of long fibre. The paper is generally applied longitudinally in a suitable covering machine which is sometimes arranged to supplement the longitudinal wrapping by a helical covering, both being applied without much tension, so as to leave as much air-space as possible between the wire and the individual wrappings of paper. In lieu of the helical wrapping of paper a whipping of thread is used. The paper used varies in thickness from 3 or 4 mils to as much as 10 mils in the case of very heavy conductors. In the case of screened conductors the screening copper tape is about 3 mils in thickness and about $\frac{1}{4}$ to $\frac{3}{8}$ in. in width applied helically with a slight overlap, its object being to screen the conductor from the inductive effect of neighbouring conductors traversed by telegraphic impulses. The screened conductors vary in diameter from 50 mils weighing 40 lb. per mile to 113 mils weighing 200 lb. per mile, and in the smaller sizes the screening tape, although rolled as thin as possible, is practically of the same weight as the conductor itself. Care is taken in stranding the wires into a cable that the screening tape is in contact with the lead sheathing and therefore earthed. The electrostatic capacity of such a conductor measured to earth is 0·097 to 0·133 microfarads per mile.

When the conductors are not screened, two wires insulated in the manner described are twisted together in a twinning machine with a definite length of lay varying in Post Office cables from 4 in. to 13 in., and each length of lay is indicated by the use of a coloured wrapping, which ensures that no two pairs of the same lay are adjacent when the pairs are stranded to make a cable or cable core. The electrostatic capacity varies from 0·04 to 0·07 microfarads per mile, and the self-induction from 0·9 to 1·4 millihenrys per mile. A rough empirical rule for determining the space requisite for any desired wire-to-wire capacity, with the class of paper and method of covering usually employed, is that if the diameter of the completed pair of wires is three times that of one of the conductors, the wire-to-wire capacity measures about 0·07. If the ratio is four to one, the capacity measures 0·055 or thereabouts, whilst if the diameter of the pair of wires is increased to five times that of one of the conductors forming it, the capacity falls to a little over 0·04 microfarads per mile.

It is not impossible, therefore, to obtain in a cable a more efficient loop with conductors weighing 100 lb. to the mile than with 150-lb. conductors; for if the latter are made to have a capacity of, say, 0·07 microfarads per mile and the former 0·045 microfarads, on the basis of k.r. alone the 100-lb. loop would be more efficient, and in addition it would have a higher inductance, say 1·2 millihenrys per mile as against as little as 0·9 millihenrys.

There is room for much ingenuity in the assembly of the pairs of wires to form a cable. The original method was to strand the alternate pairs up layer by layer in a stranding machine, each alternate layer forming a left-handed and right-handed spiral. The number of pairs thus stranded varies from seven pairs in a small distribution cable to as many as 606 pairs in the largest main telephone cable.

Two other methods of stranding the pairs are in general use:—(*a*) The quadruple pair type. (*b*) The multiple twin type, of which more is said below.

The varied requirements which multiple subterranean cables are required to meet may be classified as follows:—(*a*) Trunk-line telephone cables. (*b*) Junction telephone cables. (*c*) Main telephone cables wholly allocated to subscribers' lines from an exchange centre. (*d*) Composite cables providing for any two or three of the above services. (*e*) Composite cables primarily intended for telephonic purposes, but also containing telegraphic wires.

The chief defects in the original type which these special cables were designed to avoid are:—(*a*) Their inefficiency for anything but short-distance communications. (*b*) Their costliness in the provision of spare wires. (*c*) The waste involved in the uncertainty as to the ultimate requirements at the points selected for distribution.

They are also unsuitable for superimposed circuits, in considerable use on aërial lines to which these are often connected, and they generally provide for the short-distance subscriber's circuit the same weight of conductor as for circuits of greater length. As regards the last point it may be noticed that an ideal conductor for subscribers' circuits would be one that tapered gradually, from the longest distance served on a route to the shortest from the exchange, the wire-to-wire capacity per mile being also reduced as the length increased. This also applies to multiple trunk-line cables, in which it is rarely possible to allocate, in the first instance, the whole of the wires for suitable trunk lines. Now it is clearly impossible to secure this ideal equality of treatment in a telephonic network, nor is it possible, when multiple cables are used for trunk circuits, to provide equal efficiency for lines of varying length unless the ultimate appropriation of all the wires can be foreseen. On an aërial line, on the contrary, conductors of suitable gauge can be added from time to time. It is to meet these difficulties that composite cables, containing different gauges of wire, have been

Digitized by Google

manufactured, but their utility is limited, and they have the disadvantage that a larger number of conductors of fixed gauge have to be provided for future use. This condition naturally suggests the grouping of wires in a cable to form conductors of larger cross-section, an arrangement which cannot be carried out with any electrical advantage in the case of cables in which the pairs of wires are arranged in layers in the usual manner.

In the two types above mentioned this difficulty is met by stranding pairs in such a way that, (*a*) in addition to the individual pairs being available to form a twisted looped circuit, the wires of two or more pairs may be bunched to provide double conductivity without materially increased capacity; (*b*)

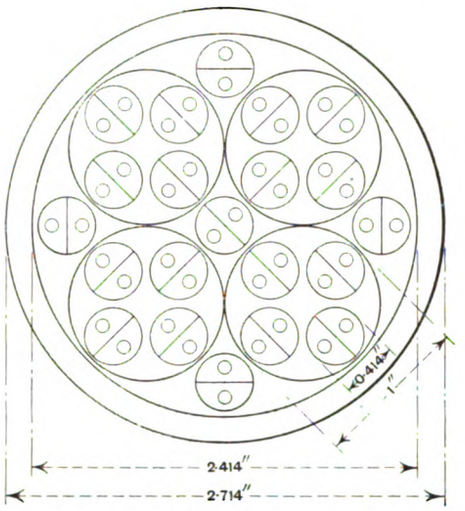

Fig. 1.

by the use of transformers the unit loops can be utilised for a circuit at the same time as those of double conductivity. In quadruple pair cable four pairs of wires are stranded around a centre of yarn, to form quadruple pair cores, and where the conductors are large enough, weighing 100 lb. or more per mile, to worm these four pairs with four pairs of smaller gauge, weighing 10 lb. or more per mile, forming an eight-pair core. These cores are then laid up into a cable of any desired number of pairs. Quadruple pair cores, being large, allow of the helical interstices formed in each layer being utilised for smaller pairs of wires, as may be found necessary.

The quadruple pair formation admits of two diagonal pairs being each bunched to form conductors of double conductivity,

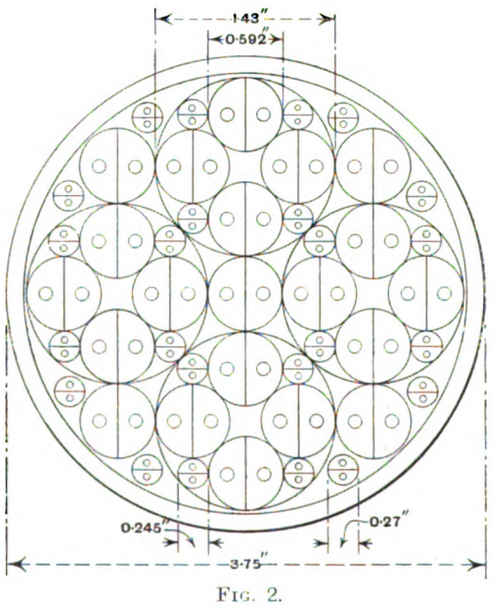

Fig. 2.

the two pairs being used for a metallic telephone circuit. The stranding of the four pairs around a common centre ensures that these loops of double conductivity shall be non-inductive to any similar loops in the same cable. The mutual capacity between these conductors of double conductivity is not materially greater, and may be made actually less than that obtained between the conductors of the unit pairs of which they are made up. An electrical advantage is thus secured, and speech can as a result be carried on over a much greater distance. In the same way all the four wires forming a part of two neighbouring pairs can be grouped together to form a conductor of fourfold conductivity, and can be associated with the other four wires, similarly grouped to form a telephone loop, this loop of fourfold conductivity being non-inductive to other loops in the cable. The capacity of such a loop is necessarily higher than that formed of diagonal pairs, but the arrangement would sometimes prove advantageous. The worming pairs can also be grouped in the same way, and the mutual capacity results obtained with this combination are interesting.

All the remarks as to bunching conductors apply to superimposed circuits, for one of these loops is obtained, in such a system, by bunching the initial conductors through one winding of a transformer. The general result obtained will be best illustrated by reference to a diagram of a 42-wire cable (Fig. 1), excellent electrical tests having been obtained with a cable of this type. It will be seen that the cable is formed of four quadruple pairs laid around a central pair of the same size and wormed with four pairs of equal weight, this being the correct geometrical formation. The wires of the pairs forming each core are laid up with a different lay, to ensure immunity from cross-talk and to ensure the same result when the pairs are bunched as described; the four quadruple cores have also different lengths of lay. The quadruple cores in this cable are about 1 in. in diameter, and the complete cable over the lead sheathing has a diameter of 2·71 in., which is nearly the maximum size permissible for a 3-in. pipe. This may be re-

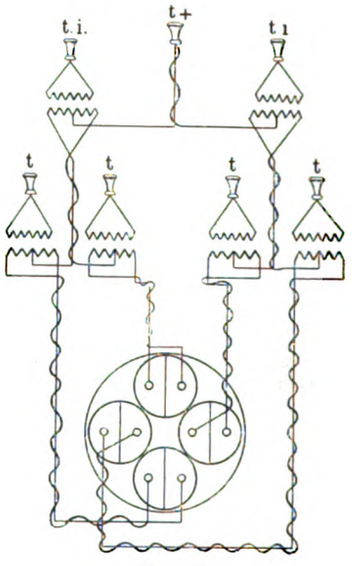

Fig. 3.

garded as typical of trunk-line cables, but for long-distance transmission it would be desirable to provide 200-lb. conductors and a cable 3¾ in. in diameter drawn through 4-in. pipes (Fig. 2). With such a cable telephonic speech between London and Manchester would be practicable. The cost, including pipework, cabling, jointing, and equipment, would be high—exceeding, probably, £300,000—but by the addition of 100-lb. worming pairs as shown in Fig. 2 and the sample on view 24 circuits would be provided, adequate for intermediate distances—a total of 48 metallic circuits. This number could be increased to about 60 by the superimposing scheme illustrated diagrammatically in Fig. 3. No doubt it would be desirable in such a case to provide for loading the cable with inductance coils at every 2 or 2½ miles.

In the multiple twin type the facility for increasing the conductivity without abnormally increasing the capacity of the heavier loop is obtained by a system of successive twinning. Two pairs of wires having been made in the way already described, these are twisted together to form a double pair. These two pairs serve the same purpose as the diagonal pairs of the quadruple core described above. A similar double pair having been prepared, the two double pairs are in turn twisted together to form a pair of fourfold conductivity (see Fig. 4). Eight-wire cores formed in this way are laid up into a cable, and although the fourfold pairs cannot be wormed with smaller conductors as can the quadruple cores, layers of them can be wormed with small groups of pairs or by single pairs as can

Digitized by Google

layers of quadruple cores. Two 8-wire cores have been paired in the same way to form 16-wire cores. A multiple twin cable of 10-lb. conductor, containing 1,212 wires, provides facilities for utilising spare wires in the outer zones of a network in the manner referred to later. Quadruple pair and multiple twin cable cores, say 2 in. in diameter, are sometimes surrounded by a layer of ordinary twin conductors or by one or more layers of screened conductors for telegraph purposes, this latter being the method adopted in the case of the former type in connection with the West of England underground system, and in the

Fig. 4.

latter type in connection with the northern underground cables and the cable now being provided between Leeds and Newcastle (Fig. 5).

Cables this completely laid up ready for sheathing are dried in ovens or vacuum chambers to raise the insulation prior to sheathing with lead by passing the core through a lead press in precisely the same way as that adopted for other lead-covered cables. Immediately after sheathing the cable is submerged, and when cool tests for conductivity and insulation are made. As regards the latter test, it is interesting to note that an insulation of from 10,000 to 20,000 megohms per mile is frequently obtained, and that if the insulation of a core is allowed to fall much below 5,000 megohms the electrostatic capacity is raised.

In this country these cables are almost invariably drawn into pipes, the sizes generally used being 3, 3¼, and 4 in., joints being made at every 176 yards, or thereabouts, and sealed by a lead sleeve and carefully-wiped joints. These joints are tested under a pressure of 30 lb. to the square inch, it being essential that the cable throughout its entire length shall be absolutely air-tight. The method of jointing the quadruple pair and multiple twin cables is interesting. Although so far as the mechanical operations of jointing are concerned the ordinary methods are followed, great care is taken that the individual main cores on one side are joined to similarly constructed cores on the other side of the joint, and that individual wires or pairs do not cross from one core to another. As a general rule multiple twin cables are laid up in 8-wire cores, and the construction of the core and method of jointing are illustrated in Fig. 4.

40 or 50 miles. At the end of these sections transformers would be installed, the primaries of which would be connected with telephone exchanges on the line of route along which traffic is probable. The secondary windings of the transformers would be connected across the *A* and *B* of the loop. The central point of the secondary winding being accessible, it would be connected to the central point of the secondary winding of a similar

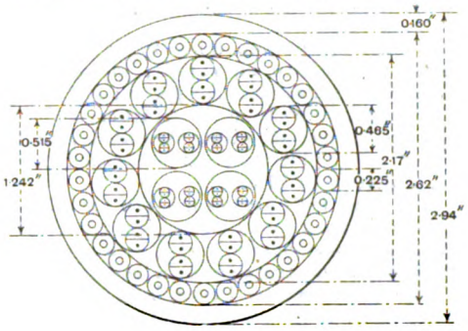

Fig. 5.

transformer connected to the *A* and *B* wires of the forward section of the same loop, this process being followed through the entire length of the cable. The diagonal loop having been similarly equipped at the same points throughout, we shall have available between the extreme ends of the cable a loop of 200-lb. conductors of low mutual capacity. The only disadvantage would be the insertion of non-inductive resistances at three or four places; whilst the great economical advantage will have been secured of having heavy conductors for communication between the termini, which have already been utilised for intermediate communications. The shorter circuits would be subject to the losses common to all inductive circuits; but doubtless transformers could be designed for such a purpose which would reduce these losses to a minimum, although the type in general use would be perfectly efficient for the distances indicated in this case. It is clear that, if four pairs forming a quadruple pair be symmetrically stranded around their common centre of yarn, the companion diagonal loops could be similarly utilised. Exhaustive experimental trials have been made on circuits 11, 33, 55, and 77 miles long in quadruple pair cables with complete success; and in addition super-superimposing has been successfully obtained by the insertion of transformers in the 200-lb. circuits and using as the *A* wire of an additional circuit two diagonal pairs of wires (400 lb. per mile), and as the *B* wire the companion diagonal pairs of wires in the same quadruple core, thus obtaining seven circuits with four pairs of

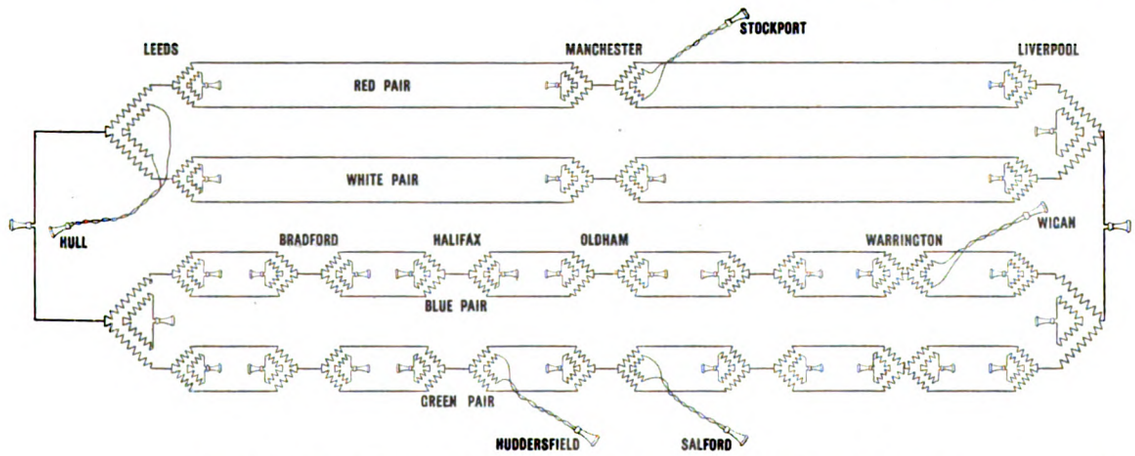

Fig. 6.—Diagram Illustrating Superimposition and Super-Superimposition.

As each of the differently coloured pairs of wires is laid up with a distinctive lay, it is necessary to follow a definite plan in jointing the pairs together, in order that the greatest immunity from inductive disturbance may be secured. Care is therefore taken in jointing these cables that (1) in any quadruple pair core similarly coloured pairs are not jointed together, and that (2) the diagonal positions of the pairs are maintained.

Superimposing.—An economical method of using such cables is illustrated in Fig. 3 by means of a quadruple pair core, but similar results are to be obtained with the multiple twin type. In the first quadruple cable cited, Fig. 1, the unit conductors, weighing 100 lb. per mile, would be used for distances up to

wire as shown in Fig. 3. There was a complete absence of cross-talk or inductive interference throughout the system.

As illustrating their utility, if cables of this type were used between Liverpool and Leeds, communication could be established between the following towns on the line of route by means of inductive circuits as described above:—Liverpool and Warrington, Warrington and Manchester, Liverpool and Manchester, Manchester and Oldham, Halifax and Bradford, Oldham and Halifax, Manchester and Halifax, Manchester and Leeds, Halifax and Leeds, Bradford and Leeds. Also by spur lines off the line of route connected to the transformers, between other places (see Fig. 6).

Digitized by Google

In this way all the unit conductors will be utilised for short-distance communications between large towns having a community of interests, and therefore likely to provide an adequate traffic. At the same time conductors of double conductivity metallic circuit would be available for traffic between Liverpool and Leeds, with extensions by means of aërial lines to, say, Hull, Goole, Grimsby, York, and other places within about 100 miles of Leeds as a centre, and similarly with Liverpool as a centre.

Considerable lengths of two other types of quadruple pair cable have been manufactured, namely, (*a*) one containing 56 conductors, each weighing 100 lb. per mile, 15 miles having been laid between Liverpool and Warrington; and (*b*) one containing the same number of wires, associated with 26 screened conductors for telegraphic purposes between Manchester and Warrington, a distance of 19 miles.

The planning of an underground network for a local telephone system on economic lines presents a fascinating problem.

Certain transmission standards having been agreed to for local and trunk purposes, and the equivalent lengths of various conductors in cable and open lines having been determined in terms of a standard cable, it is made evident that whilst conductors weighing 10 lb. to the mile are necessary for many subscribers to an exchange system, there are a large number—probably the majority—of those connected to a well-placed exchange who could be efficiently served by a conductor of, say, 5 lb. to the mile. It is doubtful, however, if so small a conductor could be safely provided in a cable of the ordinary construction, as the pairs of wires would require to take the strain of the large stranding machine used for building up the entire cable. In quadruple pair and multiple twin cables, on the contrary, pairs are first assembled in small machines into suitable cores, and these 8-wire cores so manufactured would be quite capable of taking the strain involved in the final stranding of the cable.

These two types therefore bring within practical limits much smaller conductors than are now used, with the advantage that whenever necessary they can be bunched to form 10lb. or 20lb. conductor circuits.

There is one other method of increasing the efficiency of the line, and securing approximate equality of treatment in connection with a telephonic network, viz., the economy of filling the pipe or duct, within certain limits, without regard to the number of conductors. It should be regarded as an axiom of telephone engineering that, a given duct space having been provided at a heavy cost, a main cable should as nearly as possible fill it, and a low mutual capacity be secured where the wires in the outer zone are few. Thus, if circumstances should demand that a 2½-in. cable should only have a hundred conductors, these wires should not only be heavier if necessary than those near the exchange, but widely separated, so as to have a low capacity. It is conceivable that by this means a subscriber at a distance of more than two miles from the exchange may be able to speak over a long trans-continental trunk circuit with the same efficiency as one situated only a quarter of a mile from the exchange.

It will perhaps be well to emphasise the fact that notwithstanding the great success which has been obtained by the use of telephone cables, even for considerable distances, it by no means follows that aërial lines cease to be necessary. Not only are aërial lines a vital necessity if long-distance telephonic communication is to be secured, but the enormous growth of this long-distance traffic makes it difficult to find room on the highways for all the wires required for that purpose. Moreover, the short-distance trunk circuits, largely placed in the underground cables, are not suitable for long-distance communication.

The author then referred to the method of utilising these cables for telegraphic purposes, of which Sir John Gavey, in his Presidential Address, gave some particulars. The method consists of working a telegraph circuit in a loop, and superimposing thereon an earth circuit. Hughes instruments have been very successfully employed between London and Glasgow, without a repeater, both by means of the superimposed circuit and also by the use of screened conductors. These screened conductors have also been used for long-distance undulator circuits without a repeater.

A striking illustration of the efficiency of screened conductors is the 200-lb. wire used in the West of England underground. It is probable that before the end of the next financial year conductors of this type will be available between London and Land's End, the landing-point of various Atlantic and other cables. The length of this circuit will be about 310 miles, and it is interesting to note how it compares with an Atlantic telegraph cable, and what results would follow the extension of an Atlantic cable by means of it, if such an arrangement be possible, in order that direct communication might be accomplished between London and the American stations, without retransmission at the cable stations. The length of cable from this point to Nova Scotia is 2,531 knots. Assuming that one mile of the screened conductor cable equals one mile of submarine, the 200-lb. screened conductor between this point and London would represent about 310 miles of the Atlantic cable, increasing its length to 2,800 knots. In the same way the cables landing on the west coast of Ireland could be extended to London if a screened conductor cable were provided across Ireland, South Wales, and the Bristol Channel, to replace the open wires at present used for the Transatlantic traffic by this route in conjunction with a submarine cable—57 nautical miles in length across the St. George's Channel. If a cable of Atlantic type replaced this it would increase the length of Atlantic cable landed at Valentia from 1,847½ nautical miles to 1,904, and the screened conductor cable in England, Wales, and Ireland would be about 480 miles in length, thus making the circuit equivalent to 2,321 knots of Atlantic cable. The fact that one mile of the 200-lb. screened conductor in question is roughly equivalent to one mile of Atlantic submarine cable—although the conductivity of the latter is about 2¾ times that of the former—is due to the capacity of the Atlantic cable being 0·42 microfarads per knot (0·364 per mile) compared with 0·135 per mile for the screened conductor. It, of course, remains to be seen if the screening which is effective for ordinary telegraphy would be adequate if the conductors were joined to long submarine cable wires, but whether underground cable wires be stranded in pairs for use interchangeably for telegraphic or telephonic purposes, or provided with a screening tape for the prevention of inductive interference, they are a complete success for inland telegraphic purposes.

DISCUSSION.

Mr. A. L. E DRUMMOND (District Manager National Telephone Co.) regretted that it had been impossible for members to examine the Paper before its reading, as its character was such that any discussion on the spur of the moment would do justice neither to the author nor the questioner. He thought that in reference to superimposed circuits Mr. Tremain showed even more confidence than telephone experience in the past had given encouragement for, in expecting such a high degree of safety. He thought the effect of the transformers had been rather disregarded, as these instruments were not always faultless. He thought that the tendency nowadays was towards decentralisation in telephone systems. Ten years ago the cry was "centralise"; now the opposite fashion has set in. The true policy was therefore to make a careful study of the distribution and to put up smaller exchanges, and more of them than in the past. The necessity of approximating to the ideal equality of treatment of subscribers would be met in this way rather than in finding equivalents for the ideal tapering conductor described. With regard to the methods of jointing cables, there appeared to be some chance of complication. As the results of experiments conducted some time ago by his company, they fought shy of the use of coloured covering papers, as they found that the dyes affected the wires. With reference to multiple twin wires, he would point out in passing that such cables as delivered from manufacturers would sometimes come to hand with extra pairs of wires inserted as a margin for breakages; for example, a nominal 606 pair cable might really have 608 or 610 pairs of wires.

Dr. W. N. THORNTON (Armstrong College, Newcastle) pointed out the three electrical effects playing their part in a telephone cable:—Firstly, capacity, which retarded messages by means of the surface dissipation of the electrical impulse; secondly, the inductive effect, which in a telephone cable was an advantage in wiping out the effects of capacity; and thirdly, resistance, which acted simply as an absorber of energy. In Fig. 2 the capacity of circuits at opposite ends of a diameter 45° to the vertical would be the same as that of any single pair. This was probably due to the fact that the electrostatic lines go round the sheath and not straight across the core. Analogous results had been obtained in stream-line experiments. Of course, inductance would be greater in these diagonal groups, which would be an advantage. He would like to know whether better speech was obtained in super-super-imposed circuits. This might be possible, as there was more copper in circuit.

Mr. TREMAIN (interposing to reply) said that there was not much difference either way. The super-superimposed circuits did not benefit by the greater conductivity on account of the greater capacity introduced. For short circuits having small wires the performance on superimposed circuits was better, but not for long, heavy circuits. Moreover, the effect could again be varied by the way the lines were loaded, as each electrical impulse had its own electrostatic effect.

Mr. T. B. JOHNSON (Assistant Superintending Engineer Post Office) pointed out the great influence that lead-covered cable had had on modern telephone progress. The limits of speech with the use of indiarubber and guttapercha covered cables was easily reached, and Mr. Tremain had had much to do with the development of the lead-covered cable. It is not always possible entirely to foresee the extent of service, so that it is a

Digitized by Google

wise course to provide many small wires and bunch a certain number to supply subscribers living far away from an exchange. For this purpose multiple twin and quadruple cables are useful. As a matter of fact, this course is at the present day in common use, two 20-lb. cables being, for example, bunched to make up a 40-lb. cable. He thought Mr. Tremain too sanguine with regard to super-superimposing, not so much with regard to underground cables, although the K.R. law was interfered with by the transformers, which, though non-inductive, reduced the efficiency on circuits containing them, but chiefly in cases where aërial wires were joined in. Owing to faults it is impossible to maintain these so well as to shut out slight disturbances, which, although almost negligible in ordinary practice, would be noticed in telephones where the speaking efficiency was near the point of exhaustion. He would like to know what Mr. Tremain thought of the idea of fixing copper tapes on alternate conductors only, instead of on every conductor. The copper tape would be earthed by its contact with the lead sheath. Intermediate conductors would be screened sufficiently by the presence of the copper sheath round neighbouring conductors, and much expense would be saved. It might be advisable to sheath all the inner conductors, which were very important, but was the cost of screening all the outer conductors justifiable? He asked whether it had been found that tinfoil was unsuitable for a screening material. Its cost would be much less than copper, but possibly there might be mechanical difficulties in the way of its use.

Mr. F. W. Gaskins (National Telephone Co.) pointed out that Mr. Tremain had referred to a 606-pair cable as the largest main telephone cable. He believed that in the system formally belonging to the Glasgow Corporation, and now to the Post Office, there was an 808-pair trunk. With reference to the insulation and conductivity tests mentioned as being necessary after sheathing, he assumed that the capacity tests were made at the same time. Referring to the example of trunk-service to towns mentioned, he thought that using Liverpool as a centre for the towns named was unnecessary. Was it not better to run wires direct from Leeds rather than to come back over the same ground?

Mr. Tremain, in reply, said that Mr. Johnson's doubts as to the question of using aërial lines as superimposed circuits were justified, and, as a matter of fact, branch extensions were often carried underground. As regards underground cable, however, there was no trouble to fear. It is always fine weather in a cable. In his experience with such cables, he could say that not a fault had occurred in two years. It was necessary to pump air very rarely indeed. Once lead cables were laid, they were practically sound. Only in such districts as Nantwich, where subsidence was likely to occur, was there any cause for anxiety. He agreed it was not worth while superimposing on small local circuits. The point as to the principle of decentralisation was one he was not going to attempt to settle that evening. But if a cable is provided capable of giving satisfactory service to the person furthest from the exchange over the longest distance commanded, too much copper is used. A cable may easily require 5 to 6 tons of copper per mile. In one system he came across 300 tons of copper lying spare, which he used in by bunching up. He thought that junction systems were most complicated, and considered that it was still debatable whether central systems having 10,000 or 15,000 subscribers were not the thing. Dr. Thornton's idea regarding the influence of the sheath on the capacity of diagonal conductors was new and acceptable to him. He had always put it down to cascade effect due to intervening conductors. He thought that the big drop in insulation of paper cables if the slightest trace of moisture was present might be due to the fact that continued heating made the paper more dense, and there were less points touching the wire. A point with regard to aërial wires coming down was that even if these were earthed there was no effect on other circuits in the superimposed system, as the earth virtually existed across two equal arms of a Wheatstone bridge, which balanced each other. With reference to screening, where there are two layers the screening of alternate conductors in the outer layer would be very satisfactory, though not, so far as he was aware, tried at present. Tinfoil was not strong enough mechanically, nor had it a sufficiently high conductivity to fritter down eddy currents. Copper tape could be made very thin by rolling, and manipulated in a rapidly revolving covering machine. Aluminium and also iron were now being used experimentally for this purpose, with what results he did not know. Mr. Gaskins was correct in saying that Glasgow had the largest trunk telephone cable. It had 1,616 wires.

ARTIFICIAL LOAD FOR TESTING ELECTRIC GENERATORS

SOME further contributions to the discussion on Messrs. Morcom and Morris' Paper, read on March 11th, before the Birmingham Local Section of the Institution of Electrical Engineers, and reported in Electrical Engineering, March 19th, p. 427, have been received.

Mr. Oswald T. Davis (Newcastle) wrote, referring to the author's conclusion that a successful water resistance required water with a large percentage of mineral matter in solution, that he had used the hot-well for a water resistance on one occasion for a 150-kw. 230-volt machine, sufficient current being obtained with a fairly small battery of resistance plates by reason of the high temperature of the water (about 150° F.). As a general rule, however, the circulating water discharge from a surface-condensing plant was more suitable. For a permanent resistance he favoured a brick-built cement-lined tank. For a low voltage resistance the plates (which may be of $\frac{1}{8}$ in. sheet iron for lightness) should be fixed in frames a certain distance apart, and the load controlled by raising or dropping the whole frame into the water. If the groups of plates are controlled by switches, the load may be prepared by lowering the resistance frame into the water, switching on a certain number of groups of plates, and finally securing fine adjustment by further raising or lowering, or preferably by manipulating a weir on the outlet.

He did not consider iron-wire resistances immersed in water permanent enough for standard use, but they were useful in exceptional cases. They were best arranged in a box, and should be well swept with water flowing through. If run at a density of about 10,000 amps. per square inch, their life was fairly long. For extra high voltage work it was necessary to well insulate the source of the entering water, and the writer had found a small erection resembling a cooling tower useful for breaking up the water into drops. As regards the use of choking coils, it must be remembered that ordinary commercial work only calls for power factors of 0·75 and above, and this point should be considered when designing chokers. Generally speaking, the use of choking coils on machines under test is limited to determination of the increase of excitation or voltage drop. For this reason, the period during which they are in use can be kept small, and artificial cooling may be dispensed with. On the other hand, most engineers desired to see their plant tested under a load as closely as possible approximating to that which they will be called upon to take up in everyday practice, and therefore it was best to design the chokers to enable their use on long temperature and steam consumption runs. A point often lost sight of by engineers in charge of the latter class of tests was the reduced efficiency and consequent increased steam consumption of machines when under inductive load. The extra losses (*i.e.*, increased armature and excitation copper losses) often amounted to 2 per cent. of the output, and hence will make an appreciable difference to the steam consumption.

Mr. R. K. Keer (Manchester) wrote describing a liquid resistance in one of the electrical laboratories of the Municipal School of Technology, Manchester, intended to form a load for a 25-h.p., 500-volt, traction motor when driven as a generator by another similar machine. Being of a permanent nature, the tank was built of glazed Staffordshire blue bricks, in cement, the walls being $9\frac{1}{2}$ in. thick. A $\frac{1}{2}$-in. layer of mastic asphalt was put between the two thicknesses to make it watertight. The internal dimensions of the tank are 6 ft. 9 in. by 2 ft. 6 in. by 2 ft. It is placed in a pit, the bottom of which is 4 ft. 4 in. below the level of the floor. This pit is partly roofed over with steel girders, to which machines can be bolted for testing. The space between the girders is fitted with trap-doors. The electrolyte used is a 2 per cent. solution of aluminium sulphate, the electrodes being lead plates. This makes a very clean arrangement, as there is practically no sediment or fumes formed. The arrangement of the plates is as follows. At one end of the tank are four fixed plates, each 12 in. square and $\frac{1}{8}$ in. thick. They are placed parallel to the length of the tank and at a distance of $7\frac{1}{2}$ in. from each other. The movable electrode consists of three plates, each 1 sq. ft. in area, but all shaped at the bottom. These are fixed to a simple carriage, fitted with wheels, which runs on two lengths of gas pipe placed on an incline, sloping down towards the fixed plates. When the movable plates are at this end they are completely immersed and fit in between the other plates. This gives an area of 6 sq. ft., the distance between the plates being $3\frac{3}{4}$ in. As the plates are moved away they rise up the incline, and thus rise up out of the liquid at the same time. The plates are moved from above by means of a handwheel actuating a winch through bevel gearing. A brake is provided to prevent the plates running back. The whole arrangement is well coated with anti-sulphuric paint. Connections are made to the movable plates by means of flexible cables.

This arrangement of the plates gives a very large variation of resistance. Thus, with a 1 per cent. solution, which was tried at first, the resistance could be varied from about 50 ohms, with the plates just touching the liquid, to about 0·75 ohm when they were completely immersed. The lowest resist-

Digitized by Google

ance required was less than this, so the amount of aluminium sulphate was doubled, bringing the resistance down to about 0·5 ohm. The resistance varies considerably with current density, as the following figures show. With the 2 per cent. solution and with the plates completely immersed, the resistance with 10 amps. was 0·8 ohm., with 20 amps., 0·65 ohms., gradually becoming less until with 100 amps. it was only 0·48 ohm. The "resistance" measured includes, of course, a certain amount of back E.M.F., which is constant, and, therefore, most apparent with the large currents, and helps to account for the variations obtained. Apart from this, the variation is not due entirely to temperature rise, for the readings were taken quickly before there was time for much rise in temperature to occur. To test the temperature rise of the tank, it was loaded with 25 kw. (50 amps., 500 volts) for one hour. The temperature rise at the end of the hour was 27½° C. (from 14½° to 42°). While at this temperature the resistance with plates completely immersed, and with 100 amps. was 0·335 ohm. as compared with 0·48 ohm. when nearly cold. The movable plates are connected to three separate terminals, so that higher resistances can be obtained by using only one plate. By using the middle plate as the common connection, the tank can be used for a balanced two-phase load, but will not, of course, give a balanced three-phase load.

STANDARDISATION.

TWO afternoon lectures on this subject were delivered by Dr. R. T. Glazebrook (Director of the National Physical Laboratory), on Thursdays, March 19th and 26th respectively, at the Royal Institution. The first lecture dealt with standardisation in mechanical engineering, the second with standardisation in electrical engineering.

Dr. Glazebrook commenced the first lecture by giving a brief history of the evolution of the units of measurement and weight. The earliest English standards were set up by King Edgar at Winchester; the unit of length was the yard. The lecturer had on view the original bronze yard of Henry VII., made standard in 1496, and also the standard weights of 1601. In 1670, Mouton proposed a metric system, but it was not until 1795 that the present metric system was defined and made standard in France. Although the metric system was supposed to be founded on a natural length, it was found that the measurement was not accurate enough, and now the metre is defined as the length between two marks on a metal bar at Sievre in the same way as the English standard yard is the distance between two marks on a bar of metal kept at Westminster. The present standards are thus material standards. As a natural standard of length, Clerk Maxwell proposed the wave-length of light of a definite colour. The wave-length corresponding to the red line in the spectrum of cadmium has been suggested as a suitable unit. There are, however, 1,553,163 such units to the metre. In order that the metal standards of length should not vary with temperature, they are made of an alloy called invar, which consists of one part of nickel to two parts of steel. Such a bar has a constant length at all temperatures, but takes over two years to settle down to a constant length after being annealed. Such bars are made with an **H** section, and the marks are put on the neutral plane, so that the length between the marks shall be independent of the method of support. The lengths of standard metres have been compared to within one-tenth of one-thousandth of a millimetre. When comparing end-measures by means of screw calipers or other similar instruments, it is very difficult to ensure that the same amount of contact is obtained in each case. Sir Joseph Whitworth, whose measuring machine, with which he measured to one-millionth of an inch, the lecturer had on view, used a "feeler," or a polished cylinder of metal, which is placed between the rod to be measured and the end of the screw, and the screw turned until the feeler only just passes through. Other workers used an electrical contact method. The lecturer then described the Hartmann automatic comparator, which compared standards of length automatically. In order that manufacturers can be sure that the work turned out shall be interchangeable, a system of limit-gauging is in use, that is, the dimensions of any piece of work must lie within certain limits: for instance, it might be specified that a 2-in. cylinder should not be three-thousandths of an inch out either way. Such limits for cylindrical work have been settled by the Engineering Standards Committee, and published in their reports. Screws are much more difficult to standardise, as there are several dimensions to be determined, but the same principle of limit-gauging is applied.

In the second lecture Dr. Glazebrook gave a *résumé* of the history of standardisation as applied to electrical engineering, mentioning in particular the efforts made by Lord Kelvin and the British Association Committee in 1862. In those days an accuracy of one per cent. was considered good, whereas an accuracy of one in one hundred thousand was now attained to. The lecturer described the various forms of Weber's spinning coil for the absolute measurement of resistance and the latest form of the Lorenz apparatus. Descriptions were also given of the standard electro-dynamometers and the standard cells. Comparisons and measurements are still being made with the Clark and Weston cells, and the lecturer showed how most of the differences in the values obtained by different observers have been explained, and how values have been fixed and universally accepted. With regard to the standardisation of electrical machinery, the Engineering Standards Committee have drawn up some rules for the rating of machinery, but this work is not yet quite complete. As a basis for the rules, several series of experiments have been carried out by Mr. Rayner at the National Physical Laboratory, and Dr. Glazebrook gave a brief summary of the results obtained. One series of experiments consisted in determining the distribution of temperature in the interior of dynamo-coils. It was found that the maximum temperature, as determined by thermo-couples in the interior of the coils, was some 10 to 20 degrees Centigrade higher than the average temperature as determined by the resistance method. Tests on insulating materials showed that the mechanical and electrical properties of most insulators were not adversely affected if subjected to temperatures up to about 125° C., and consequently the Engineering Standards Committee have decided that ordinary stationary coils should be allowed to rise in temperature 60 degrees Centigrade above an assumed room temperature of 25° C. This rise must be determined by the resistance method, which gives the average temperature of the coil. Coils of insulated wire, impregnated with a heat-carrying enamel or varnish, are not included in this rule, as, owing to the more favourable distribution of temperature, a higher average temperature can be allowed. The lecturer then described the standard lamps used for comparing and measuring the candle-power of electric lamps, and showed some curves obtained by Mr. C. C. Paterson for the falling off in the candle-power of lamps with time (see ELECTRICAL ENGINEERING, Vol. I., p. 193). In general a lamp drops some 20 per cent. in candle-power after 500 hours' working. The Engineering Standards Committee have already issued a standard specification for carbon-filament lamps, in which efficiency, length of life, and uniformity of candle-power are some of the factors considered. The International Electrical Commission, a meeting of the Council of which will be held in the autumn of this year, originated in the work of the Engineering Standards Committee. Amongst the subjects down for consideration by this Commission are the standardisation of nomenclature and symbols, and the classification of electrical machinery and apparatus.

Portable Engine Tests.—We understand from Messrs. R. Wolf, who, as is well known, make a speciality of self-contained portable and semi-portable engines complete with a special form of combined boiler and superheater, that some exceptionally good results have been obtained in a series of tests of a new 100 B.H.P. semi-portable set of their manufacture, conducted by Prof. M. F. Gutermuth, of Darmstadt. The figures attained were 1·045 lbs. of coal per B.H.P. hour, and 8·661 lbs. of steam per B.H.P. hour. Particulars of the degree of superheat and steam pressure are not given.

Electrical Engineers and the New Army Scheme.—The Birmingham Local Section of the Institution of Electrical Engineers has issued a circular letter stating that the County Association of Warwick has authorised Mr. J. F. Lister to raise in the Birmingham district three telegraph companies for the Territorial Army, and the assistance of the Institution of Electrical Engineers, through its Local Sections, has been solicited in the matter. The companies will consist of:—One Wireless Telegraph Company, consisting of 3 officers and 66 men; one Cable Telegraph Company, consisting of 6 officers and 150 men; and one Airline Telegraph Company, consisting of 7 officers and 282 men. The training will consist of about 20 drills and at least 8 days' annual training, which will probably take place at such a time as to include August Bank Holiday week. All officers and a good proportion of non-commissioned officers and men are mounted. The County Association provides the mounts. The minimum period of service is four years. The necessary outfit for an officer will cost about £40. If an officer wishes to purchase a complete outfit, including full dress, &c., the cost will probably be £60 or £70. Part of this expense is met by a Government grant of £20 on appointment. In addition, officers and men during training in camp will receive pay at army rates. For officers this rate would be from 10s. per day according to rank. The County Association will provide necessary uniform, equipment, &c., for non-commissioned officers and men.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

ATTENTION is often drawn to the fact of the enormous quantities of aluminium minerals which are found in nature, and one always regrets that, so far, it has not been found possible to employ most of these compounds for the manufacture of the metal.

As is well-known, bauxite and cryolite are practically the only sources from which, up to the present, it has been found possible to manufacture aluminium. E. Viel, in the French patent 380.087, of September, 1907, now suggests a method for the employment of aluminium silicate. He reduces in the electric furnace a mixture of the silicate, carbon, oxide of iron and chalk, and presumes that the following reaction takes place :—

$$Al_2O_3(SiO_2)_2 + FeO + CaO + 2C = 2Al + FeSiO_3{\cdot}CaSiO_3 + 2CO + O.$$

The aluminium so obtained contains from 3 per cent. to 5 per cent. of silicon, which, of course, would spoil it for commercial purposes. He, however, removes the silicon by melting down the aluminium with a small quantity of ferrous oxide or copper oxide, according to the equation

$$Si + 2FeO = SiO_2 + 2Fe.$$

It will be noted that in the equation metallic iron is liberated. This iron is said to sink to the bottom of the aluminium bath, and finally metallic aluminium is obtained of 99 per cent. purity.

If it is possible to work such a process, it should go far to cheapen the manufacture of aluminium, because aluminium silicates are obtained in enormous quantities. According to the author, oxygen gas is liberated, as shown in the first equation. This seems very unlikely to take place, because it would be certain to unite with the molten aluminium. However, by the addition of another atom of carbon to the equation, this oxygen could be removed. But, of course, there might then be a tendency for the formation of aluminium carbide.

In the electrolytic preparation of chlorates and perchlorates of the alkali metals, it is by no means easy to obtain good current yields, one of the reasons being the reducing action which takes place at the cathode; and it is always found disadvantageous for free alkali or hypochlorite to be formed. The formation of the latter at the temperature of the bath often causes evolution of oxygen, and this means low current efficiency. In order to get over the danger of reduction, small quantities of alkali chromate are generally added to the bath. The action is presumed to be due to the momentary formation of a protective coating of hydroxide upon the cathode. To prevent the bath becoming alkaline, M. Couleru, in the German patent 195.639, recommends the addition to the electrolyte of metallic chlorides, which form, in the presence of alkali, insoluble oxides or hydroxides, and finds that the addition of magnesium chloride or lead chloride works satisfactorily.

In the first case, magnesium hydroxide is inclined to settle upon the cathode, and this also helps to prevent reduction. In the second case, lead chloride, after it has been converted into hydroxide, will react with any hypochlorite which may be present, and become converted into lead peroxide, which can be afterwards filtered off, and forms a valuable by-product.

It is claimed that the current yield is 90 per cent. for potassium chlorate, and 85 per cent. for sodium chlorate.

In the *Chemiker Zeitung* of the 25th, A. Lottermoser contributes an article upon "The Preparation of Metallic Filaments for Electrical Glow-lamps, especially from Colloidal Metals," in which the ordinary methods of wire drawing and squirting as employed in the tantalum and tungsten filaments respectively are referred to, and the well-known work of Dr. Kuzel, of Vienna, on colloids is described. For some years past it has been well known that metals can readily be converted into the colloidal state by electrical means, such as causing a high potential electrical discharge to pass between two poles in water or by various chemical means. Dr. Kuzel, in 1905, patented a method for preparing colloidal tungsten, molybdenum, silicon, titanium, thorium, &c. The metals cannot be reduced to the colloidal condition by ordinary mechanical means, but Kuzel converts them into the colloidal or hydrosol condition by first grinding them or producing them in a very fine powder, and then treating them with acid and alkaline fluids and in-between washing out with distilled water. As alkaline and acid fluids, mainly acids and bases in aqueous solution, are employed, and it is remarkable what a large quantity of a metal can be converted into the hydrosol. The fluid hydrosols are not in a condition to be directly employed for making incandescent filaments, as it is necessary first to get them into a condition in which they will be plastic. The hydrosol is in general treated with an electrolyte, which causes the hydrosol to be converted into a precipitate of a more or less pasty or plastic consistency. It appears to make a great difference in the plasticity of the precipitate what electrolyte is employed. Some electrolytes give great plasticity, and the precipitate can be forced through fine openings and form long filaments which do not break off. On the other hand, other electrolytes do not have this property, and the parts of the filament have no adhesion. For example, silver hydrosol prepared in weak alkaline solution with a complex ferrous solution is quite plastic. But if prepared with pure ferrous sulphate, it is non-adherent and non-plastic. According to Kuzel's method, then, the metallic hydrosol is precipitated by means of a suitable electrolyte. The paste so obtained is pressed through fine orifices, and the filament ignited, either in a reducing atmosphere—to reduce any oxide produced—or in an inert atmosphere. The filaments so produced are of pure metal, and contain no carbon.

ELECTRICAL SCIENCE

British and American

Terrestrial Magnetism.—The annual Report of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington has just reached us. A large part of the Report deals with the third cruise (1907) of the magnetic survey yacht *Galilee* in the Pacific Ocean. This cruise has already extended over some 22,000 nautical miles, and a complete record of the magnetic declination, magnetic inclination, and intensity of magnetic force has been secured at distances averaging 200 or 250 miles along the entire route. Along some of the well-traversed routes of the Pacific there were found declination errors amounting to 3°. These are errors of serious importance to navigators. Among the land observations of the Department, the most interesting are those made in Alaska. At Treadwell Point is an anomalous local magnetic pole. Here a source of local attraction exists which affects the mariners' compasses about 8° at a distance of a mile. Its concentration is so intense that a movement of a few inches in a horizontal or vertical direction shows considerable changes in the magnetic elements. For example, a compass carried 2 or 3 feet horizontally at a height of 5 ft. above the earth's surface changed its direction by nearly 180°. The Report states also that the magnetic and electric observations made during the solar eclipse of 1905 are nearly ready for publication, and they show that there is an observable magnetic fluctuation in connection with a total solar eclipse.

Electric Discharges through Gases.—At the Royal Institution, on Saturday last, Prof. J. J. Thomson delivered the fourth of the course of lectures on this subject. The lecturer commenced by showing an experiment illustrating how a volume of gas could be maintained in a conducting state although the ionising agent had been removed. A discharge was started, by means of an induction oil, between two metal electrodes about two inches apart in an exhausted tube containing a small amount of helium. The discharge was continued with only 200 volts, and at 270 to 300 volts the luminosity of the tube was, the lecturer added, intense enough to be of practical use if the absorption of the helium by the electrodes could be overcome. This continued conductivity was explained by the fact that the negative particles, in their passage to the positive electrode, collided with the molecules of the gas and broke off other negative particles and, of course, corresponding positive particles. The presence of these secondary ions was then shown by the following experiment :—A lime spot on the cathode of a Wehnelt exhausted tube, raised to a high temperature, emitted a bright pencil of rays, which was a stream of negative particles. This pencil of rays was surrounded by a haze, consisting of the secondary negative particles. This haze disappeared in the neighbourhood of a negatively charged plate, showing that it consisted of negative particles. In a gas at a pressure of 1 mm., each negative particle would produce another by collision in every half millimetre of its path, so that after a length of n millimetres, one negative particle would have given rise to 2^{2n} particles. With increased pressure there would be more collisions, but a stronger electric field would be required to give the particle the necessary velocity, the length of the path between collisions being reduced. Prof. Townsend, of Oxford, had found that the maximum effect was obtained when the E.M.F. in volts per centimetre divided by the pressure in millimetres was equal to 800. Prof. Thomson then described another experiment, showing that negative particles were produced by the impact of positive particles on a plate negatively charged. In the case of a

Digitized by Google

continuous discharge, the supply of negative particles to carry the current to the anode was, he said, dependent on the impact of the positive particles on the cathode. The lecturer then showed Hittorf's experiment, illustrating that an electric discharge prefers a long path to a short path at low pressures, and explained it by the statement that the positive particles could not accumulate a sufficient amount of kinetic energy, in the space of the short gap, to produce negative particles at the cathode. The number of negative particles produced was proportional to the energy with which the positive particles reached the cathode. At normal pressures, a large number of particles reached the cathode with a small amount of energy each, but as long as the total amount was large enough, a discharge could pass. A spark could not be produced, Prof. Thomson said, with a potential difference of less than 340 volts unless the length of the gap was so small as to be comparable with the wave-length of yellow light.

Continental

Magnetic Properties of Electrolytic Iron.—The behaviour of electrolytic iron offers many magnetic anomalies which can hardly be said to be cleared up satisfactorily. A valuable contribution towards this end is made by K. Schild in No. 3 of the *Annalen der Physik*. He used an anode of platinum, a cathode of copper, and an electrolyte of ferrous ammonium oxalate. As regards magnetic permeability, the electrolytic iron obtained was found to behave like cobalt in weak fields not exceeding 15 gauss. In stronger fields it behaved like soft wrought iron, approaching saturation at some point above 120 gauss. In the matter of hysteresis, however, electrolytic iron behaves, not like soft wrought iron, but like hard steel. Near saturation, the hysteresis per cycle and per c.cm. was as high as 56,900 ergs. Another remarkable property of electrolytic iron is its high coercive force. In soft iron, magnetisation may be cancelled by an opposite field of 1 to 3 gauss. Electrolytic iron requires 5 to 15 gauss. In order to shed some light on the molecular theory of magnetism, the author obtained the deposit in magnetic fields of various strengths. He found that the magnetisation so obtained is two or three times as intense as that obtained by subsequent magnetisation. The difference represents the molecular resistance to magnetisation in the solid state.

Photoelectric Cells.—Selenium cells are more convenient as reagents for photoelectric effects than sodium cells, since they require no vacuum or protection from oxidation. But there is no reason why sodium cells should not be improved and made available for photo-transmission. In the *Physikalische Zeitschrift* for March 15th, H. Dember begins by studying the gradual loss of sensitiveness in these cells, which may be called Hallwachs cells on account of their being based upon the Hallwachs effect (discharge by illumination). Like Elster and Geitel, the author used a liquid alloy of sodium and potassium enclosed in a bulb containing hydrogen, and illuminated the liquid surface with ultra-violet or other light passing through a quartz cover-glass. He claims to have eliminated any possible "fatigue" due to oxidation, the formation of ozone, or the influence of the cement used for the joints. Nor could any fatigue be observed on repeated illumination—a valuable point as regards practical applications. The maximum effect is obtained when the hydrogen has a pressure of 0·33 mm. In 87 days the sensitiveness to light decreased 25 per cent. In 30 days it decreased 7·6 per cent. This may be due to the occlusion of some of the gas, and the reduction of the pressure below that required for maximum sensitiveness, but the author makes no decisive statement.

Duration of Cathode Emission.—The duration of emission of cathode rays in vacuum tube discharge has hitherto only been observed indirectly by measuring the duration of emission of Roentgen rays. But it is quite conceivable that the latter only become perceptible after they have acquired a certain intensity, and this may take some appreciable time. A direct determination has now been made by P. Doglio, who communicates his results to the *Physikalische Zeitschrift* for March 15th. He finds the cathode flash to last 0·0002 to 0·0003 sec., according to the capacity contained in the circuit. This is slightly less than the very uncertain value deduced by Broca from the mean current, but a good deal greater than the values obtained by Brunhes and Colardeau from Roentgen-ray observations. The author used a Braun fluorescence tube, and gave the cathode spot a circular motion by means of two coils with fields at right angles and a difference of phase of 90°. The current was interrupted 10,000 times per second, and only the break current was sent through the tube. The rotation was accelerated until the circular arcs of light coalesced into a complete circle. Instead of a circle, an ellipse can also be obtained by using a single coil with copper core, and axis making an acute angle with the vacuum tube.

Wehnelt and Simon Interrupters.—In a Paper "On the So-called Electrolytic Interrupters," contributed to No. 3 of the *Annalen der Physik*, P. Ludewig combats the idea that the interrupting action at the active point of Wehnelt's interrupter is purely thermal. That a genuine electrolytic action intervenes may be proved by calculation. In one actual case the platinum point had a surface of 7 sq. mm. The current was 3·45 amperes, and the period of interruption 0·01922 sec. During that period 3·542 c.mm. of oxygen must have been evolved, which would alone produce a layer of gas ½ mm. thick on the anode. For Simon's hole-interrupter, on the other hand, a thermal theory suffices, and the author extends it to cover a wide range of pressures and temperatures. Klupathy's idea that the interruption in Wehnelt's instrument is due to Peltier heat is untenable. That Wehnelt's interrupter only works with the point as anode, not as cathode, is best explained by the hypothesis due to Stark and Cassuto, according to which an arc forms between a point cathode and the liquid. The hole-interrupter is to be preferred for X-ray work on account of its lower "make" inductance. The author reproduces some interesting current curves obtained by means of the oscillograph.

AUTOMATIC SIGNALLING IN THE HUDSON RIVER TUNNEL

THE *Electrical World* contains an account of the block-signalling, interlocking and automatic train stopping equipment of the recently opened tunnels of the Hudson and Manhattan Railroad under the Hudson River, which were described in Electrical Engineering, March 12th, page 395.

The signals are placed on an average of 367 ft. apart. The minimum distance where speed is low is 115 ft., and the maximum is 1,620 ft.

The signals give three indications: "proceed," indicated by green light; "proceed with caution," yellow light; "stop," red light. As the consequences of a train passing a signal in the "stop" position may be disastrous, a device for automatically stopping such train is used at each signal. This consists of two movable short arms or trips placed alongside each rail. When the signal is in the "stop" position these arms are raised to engage with the trigger of a valve in the air-brake pipe of the train, releasing the air and setting the brakes. Each car is equipped with two of these valves—one on each end and on opposite sides of the car. When the signal moves again to the "proceed" position, the electric motor moves these train-stop arms out of "stop" position, thus permitting the train to pass without setting the brakes, the arms being returned to stop position by gravity after the train has entered the block. This automatic method of train control is in successful use on the Boston Elevated Railroad and on the New York Subway express tracks. On these lines, however, only one automatic stop is used to protect a train. In the Hudson tunnels, two stops are used, thus insuring a greater measure of protection.

An important feature of the system is that both rails of each track are used for the train propulsion current and also for the signal current. This arrangement permits of broken rail protection—that is, a broken track rail will interrupt the circuit and so cause the display of a "stop" or red signal, and the operation of the automatic stop if the "stop" signal be displayed.

All of the switches are under the control of the interlocking devices, consisting of seven plants—one at the Hoboken Terminal (the largest), two at Caisson No. 1, two at Caisson No. 2, one at Greenwich Avenue, and one at Nineteenth Street, of which there are seven installations. The interlocking is by the all-electric system—the switches being operated by electric motors at each switch. The signals are of the same type as used in the block system, and are controlled from the machines, the levers of which are so interlocked that it is possible to make only such movements as have been previously arranged for; conflicting movements are in this manner absolutely guarded against.

An interesting feature of this plant is use of the illuminated track diagram similar to that employed on the London Underground Railways. This is a diagram or chart of each track lay-out painted on glass, and placed in front of each machine for the information of the operator. Each line of track has a row of small electric lamps placed back of the glass; these lamps are controlled from the different track sections; when the tracks are unoccupied the lamps show a bright green light; as soon as a train enters the limits of the interlocking, the light controlled by the track on which the train is running is extinguished, so that movement of a train along the track can be followed by observing the corresponding movement of the dark space along the track on the diagram.

New Telephone Charges.—At a meeting of the Council of the Bradford Chamber of Commerce on Wednesday last week, a fund was started for the purpose of carrying on the agitation against new telephone charges. The president of the Council, Mr. H. A. Foster, has given £100, and the Chamber recommends each member and each telephone user in Bradford and district to make a contribution of at least one guinea.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published March 26th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.
Names in brackets indicate communicators of inventions from abroad.

1907 Patents

4,709, R. A. Fessenden. For receiving messages by wireless telegraphy, the use of three tuned receiving circuits, one tuned to the period at which it is desired to receive, one tuned to a higher period and one to a lower period. The higher and lower period circuits neutralise the effect of disturbing impulses produced on the receiver by the properly tuned circuit. The higher and lower period circuits should be damped by eddy-current or resistance losses to a higher degree than the middle one. By using a receiver tuned to group frequencies as well as to wave frequencies, the selectivity is still more pronounced. Multiplex telegraphy may be accomplished by arranging the circuits in groups of three or more, each group being arranged to respond only to a single frequency. Eleven claims, thirteen figures.

4,710, R. A. Fessenden. In signalling by electromagnetic waves, the electrostatic component of the waves has hitherto been utilised, the receiving or transmitting device consisting of a long vertical antenna as an upper capacity, and a horizontal wire or network as a lower capacity. If, however, the magnetic component of the waves is utilised, a horizontal wire only is necessary. According to the present invention, this can consist of a single iron wire or a bundle of iron wires of such a length as to be in tune with the waves which it is desired to generate or receive. This wire or bundle of wires is supported on insulators at a height of about two feet above the ground. The wire should be capable of rotation in a horizontal plane, as it is not responsive to waves reaching it in the direction of its axis. The wire is surrounded at its centre with a coil of wire in series with condensers and spark-gap in the case of a transmitter or with some form of detector in the case of a receiver. This specification also describes a method of inductively insulating the steel mast or metallic guy-ropes of antennæ (for signalling by means of the electrostatic component of electromagnetic waves). The lower part of the mast as well as the guy-ropes are surrounded by coils of fine iron wire, and their impedance thus increased. This prevents the mast or guy-ropes from carrying off the energy sent out or received by the antennæ. Thirteen claims, six figures.

5,671, British Thomson-Houston Co. and B. Hopps. An improvement in the system of control of electrically propelled vehicles of the type, fully described in Electrical Engineering, Vol. I., page 463. In this system the generator field is weakened when it is desired to change the connections of the driving motors. The resistance in the generator field circuit, according to the present invention, is controlled only by the foot-pedal, but the main controller and the foot-pedal are interlocked so that the generator excitation is reduced when the controller is in the off position or when changing from one running position to another. The foot-pedal is also connected to the governor or throttle valve of the engine, so that when the generator voltage is reduced the supply of motive fluid to the engine is also reduced. Four claims, one figure.

5,741. British Thomson-Houston Co. (*General Electric Co.*). Ring-like flanges of non-magnetic material, such as brass, cast on the pole-pieces of the commutating poles of electrical machinery. Transverse ribs, which fit into recesses in the pole-face, are provided. These break up the pole-face into a number of portions each surrounded by a closed circuit, which acts as a damper to prevent sudden magnetic fluctuations. The brass flange also forms a support for the exciting winding. A flange at the other end of the pole may be cast in one piece with the core. Three claims, three figures.

5,749. Griffiths and Bedell. An improved cable for use with the G.B. surface-contact system of electric traction (see Electrical Engineering, January 2nd, 1908, p. 7). The cable, which consists of a layer of copper strands over a jute core, and then a layer of galvanised iron strands, is further provided with a series of short iron sleeves. The smooth cylindrical contact surface obtained gives a better contact and decreased wear of the carbon surface of the switch. The short sleeves are butted together, but are not connected together. One claim, two figures.

14,203, British Thomson-Houston Co. (*General Electric Co.*). Wedges for closing magnetically and mechanically the slots of alternators or induction motors, and composed of a bundle of iron or steel wires suitably insulated from one another, or a rolled-up strip of woven iron or steel wire fabric. In each case the magnetic wedge is surrounded with an insulating cover. The iron or steel wire fabric should be well japanned to insulate the layers from one another. Three claims, three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.
Summaries of the more important of these patents will appear in our next issue.

1907 Patents

5,339. Leitner. Quick acting "make and break" switches.
5,508. Lamme. Alternating current commutator motors.
5,522, James Hawley, Ltd., & Jones. Electro-magnetic separator drum for grain conveyors.
5,564A, Mershon. Control of alternating current motors.
5,652, Fynn. Alternate current motors.
5,853, Skinacker & Plisnier. Wireless telephony.
6,064, Brecknell, Munro, & Rogers, Ltd., & Munro. Bow trolleys or collectors.
6,083, Morris & Lister. Electromagnets.
6,224, Handcock, Dykes, & Smith. Fuses.
6,279. Kitsee. Electric telegraphy.
6,288, Metcalfe. Electric trembler coils.
6,409, Sir W. G. Armstrong, Whitworth, & Co. & Honner. Electric lighting of railway vehicles.
6,417, Torrens. Electrical ignition apparatus.
6,847, Johnson-Lundell Electric Traction Co. (*Lundell*). Dynamo-electric machines.
6,869, Burnup & Kirk. Time controller for electric signs.
7,953. Archibald. Electric transmission of power from a prime mover for automobiles.
8,764, British Thomson-Houston Co. (*General Electric Co.*). Controlling devices for electric motors.
9,652. Watson. Electric switches.
9,683. Storer. Voltage regulators.
9,962, British Thomson-Houston Co. (*General Electric Co.*). Electrically-operated signals.
10,440, Browne. Microphones for telephones.
11,594, Allgemeine Elektricitäts Ges. Rolling-mill motors.
12,529. Maiche. Inductive telegraphy and telephony.
12,559. Carpentier. Sparking plugs.
15,656, Daley & Daley. Automatically-operated station indicators for electric railways.
17,690. Stone. Space telegraphy.
19,274. Eisenstein. Receivers for wireless telegraphy.
21,173, Siemens Bros. Dynamo Works, Ltd. (*Siemens Schuckertwerke Ges.*) Automatic switches.
23,037. Conrad. Alternating-current motors.
23,098. Schott & Carl-Zeiss-Stiftung. Incandescent lamps.
23,225. Timar & Von Dreger. Arc lamps.
26,081. Meyerling. Meter for direct current.
27,232. Meyerling. Ampere-hour meter.
28,425. Allgemeine Elektricitäts-Ges. Measuring instruments.
28,542. Hiorth. Electrical induction furnace.

1908 Patent

660. Allgemeine Elektricitäts-Ges. Multiple-rate meters.

Complete Specifications open to Public Inspection before Acceptance.

1907 Patent

12,634, Galletti. Methods of producing electric oscillations.

1908 Patent

4,432, Maschinenfabrik Oerlikon. Single-phase commutator machines.

Applications for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of March 25th.

2,260 of 1900. The British Westinghouse Electric & Manufacturing Co., Ltd., seek leave to amend the specification numbered as above, granted to Hugo Bremer, for "improvements in electric arc lamps." The proposed amendment consists in eliminating portions of the specification, including the first six claims and figures 1 to 4 and 7, on the ground of doubtful validity.

Expiring Patents

The following patents expire during the current week, after a life of fourteen years:—

6,888, of April 6th, 1894. J. Imray (*La Société Anonyme pour la Transmission de la Force par l'Electricité*). Telegraphic or telephonic transmitting and receiving apparatus for transmitting undulations of various periods along a single line simultaneously.

7,050, of April 9th, 1894. G. C. Fricker. Electrically illuminated signs in which the lamps are switched on or off progressively by the action of a rotating commutator.

LOCAL NOTES

ALTRINCHAM: *Purchase of Electric Supply Co.*—A valuation is being made of the Altrincham electric supply undertaking with a view to purchase.

ARGENTINE: *Buenos Aires.*—It is stated in the *Review of the River Plate* that the Cia. Alemana Transatlantica de Electricidad is about to increase its capital so as to give greater impulse to its business in Buenos Aires, Montevideo, and Chile. A new issue of bonds to the extent of 25 million marks is to be made, half of which will shortly be offered to the public. In 1906 the capital of this company was increased from 36 to 72 million marks, the 15 million marks in debentures, which was the original issue, was increased to 30 million in 1906, so that with the new issue the debentures will amount to 55 million marks, and the total capital of the company in shares and bonds will be 127 million marks.

Rosario.—The Rosario Electric Lighting Company, owing to increasing demands, is increasing the capacity of its generating station by the installation of two 2,000 kw. generating sets. A new chimney has been built, and a Green economiser is being put in. Extensions are also being made to the distributing system.

La Plata.—Mr. Otto Franke, concessionaire for a high-speed electric railway between La Plata and the Federal capital, has deposited the $50,000 guarantee stipulated in the contract.

ASHTON: *Guardians' Electricity Scheme.*—The Board of Guardians have been informed that their application to the Local Government Board for permission to borrow £2,000 for an electric lighting installation for the new hospital and workhouse has been refused. The reason is given that it would be possible to purchase electrical energy from the local authority at a cheaper rate than the Guardians could themselves generate.

AUSTRALIA: *Kalgoorlie.*—According to the *Australian Mining Standard*, extensions to the power plant of the Kalgoorlie (W. A.) Electric Power Corporation have been made to the extent of 1,600 h.p. The new machinery was purchased recently in England during a visit by Mr. E. C. Crocker, the company's General Manager. The tramway system now open in Kalgoorlie has a total length of 20½ miles, and the gross receipts for the year 1907 amounted to £47,822.

Claremont.—Having successfully floated a loan of £4,000 at 4½ per cent., the Municipal Council has recently installed a battery booster at the power station. The report for 1907 shows that 102,487 units were generated, compared with 90,099 for the year 1906, whilst the number of consumers increased from 205 to 284. There are 237 street lamps, the length of streets lighted electrically being 16¾ miles. For the year 1907, the undertaking, which was opened in February, 1905, showed a surplus of £1,004 over working costs.

Melbourne.—Two 750-kw. Westinghouse-Parsons' turbo-generating sets, supplied by the British Westinghouse Electric & Manufacturing Co. through their local agents, Messrs. Noyes Bros., have recently been put into operation. These machines are to supply power under the new system which is being installed by the City Engineer, Mr. Harper, for the outer network of distribution.

BELFAST: *Car Cleaners' Wages.*—A report has been presented by Mr. A. Nance, General Manager of the tramway system, on the question of the wages of car cleaners. He comments strongly upon the discontent which appears to be rife, and points out that if he were given a free hand he would at once discharge all the present cleaners and take on new ones, for he is confident that he could get 20 men for every one of them at 24 hours' notice, and for 5s. per week less wages if desired.

Police Tramway Facilities.—Mr. Nance has also reported upon an application by the City Police Commissioner that all members of the police force should be allowed to travel upon the cars by a free pass in return for an annual payment of £500. Mr. Nance points out that for the 350 Post Office officials to travel "free" upon the trams the sum of £1,250 per annum is paid. In the case of the police force there were 1,040, and it was reasonable to suppose that they would take more rides during the year than the Post Office officials. He therefore does not recommend the acceptance of the proposal of the Police Commissioner as it stands.

Electricity Works.—Mr. A. B. Wilson has been asked by Messrs. Coombe, Barber & Coombe to act as arbitrators between them and the Corporation with regard to the engines which they have supplied, as sub-contractors to Messrs. J. G. White & Co., in connection with the tramways.

BISHOP AUCKLAND: *Electrical Sewage Pumping.*—The Local Government Board have approved of a scheme of main sewerage and sewage disposal for the Denebeck Valley. The work consists in the laying of several miles of main outfall sewers, the sewage from which will gravitate to the disposal works situate at South Church, with the exception of the sewage from South Church, which is proposed to be pumped by electrically-driven centrifugal pumps to the disposal works. The engineers of the scheme are Messrs. D. Balfour & Son, of London and Newcastle-on-Tyne.

BOURNEMOUTH: *East Cliff Electric Lift.*—It is stated that the new electric lift which has been erected on the East Cliff will be ready for use at Easter. A second lift on the West Cliff is in course of construction.

BRIGHTON: *Lecture on Electricity Undertaking.*—Mr. J. Christie, the Engineer and Manager of the electricity undertaking, gave a lecture at the Free Library on Thursday upon the origin and progress of the municipal electric lighting undertaking. He recalled that Brighton was one of the first towns in the United Kingdom to have a public electric supply system, and mentioned that the original Hammond Co., in 1882, had total costs from 1s. 4d. to 2s. per unit. Having traced the various stages of development, the lecturer gave the following figures showing the progress of the undertaking during the last fourteen years. In 1892 the consumers connected were 215, with an equivalent lamp connection in 8 c.p. lamps of 11,229, whilst the units sold were 156,110. The capital expenditure upon the undertaking was £55,1[illegible], and the total revenue for the year was £4,687. At the end of the 1907 financial year there were 4,500 consumers connected, the connections being the equivalent of 307,604 8 c.p. lamps, whilst the units sold were 7,849,194. The capital expenditure upon the undertaking was £758,297, and the total revenue £81,415.

The Action re Vibration.—At the last meeting of the Corporation, a special vote of thanks was passed to the Town Clerk, Mr. H. Talbot, for his successful conduct of the recent action in regard to vibration at the North Road sub-station.

DENTON: *Runaway Tramcar.*—A car belonging to the Oldham, Ashton, and Hyde Electric Tramway Co., whilst going down a steep incline in the direction of Hyde known as Broomstair Brow, got out of control on Wednesday last week, and leaving the rails dashed into a boundary wall at the bottom. Several passengers were injured, but none seriously. It is stated that the snapping of the brake chain was the cause of the accident.

FINCHLEY: *Bulk Supply.*—The Electricity Committee has had several interviews with representatives of the North Metropolitan Electric Power Supply Co. with reference to a bulk supply, but the Council has endorsed the opinion of its committee that no satisfactory basis can at present be arrived at.

FREEMANTLE: *Electricity Charges.*—A new schedule of charges has been adopted, ranging from 7d. per unit for a consumption not exceeding 75 units per month, to 4½d. per unit for 500 units and over per month.

GLASGOW: *Tramway Extensions.*—The Corporation Tramways Committee has had under consideration the question of extending the tramways to Burnside, Rutherglen, and Rouken Glen. It has been decided to defer consideration of the subject until the general policy with regard to tramways extensions is defined.

GLOUCESTER: *Charge for Tramway Energy.*—A special report of the Electricity Supply Committee deals with the question of the charge for current to the light railway undertaking. The report states that the present charge of 1d. per unit is a reasonable and fair one, but one member of the Committee thought it should be somewhat higher. A recommendation was made by eight votes to three, recommending that the present charge of 1d. per unit be continued. At a subsequent Council meeting an amendment was passed referring the matter to Mr. R. A. Chattock, the City Electrical Engineer of Birmingham, for settlement.

HANWELL: *Bulk Supply.*—Negotiations are proceeding between the Ealing Urban District Council and the Hanwell Council with regard to a supply of electricity in bulk.

Transfer of Lighting Order.—The Council's consulting engineer recommends that arrangements be made with the Metropolitan Electric Supply Co. for the taking over of the Council's Electric Lighting Order.

LANARKSHIRE: *Tramway Extensions.*—The Lanarkshire Tramway Company has begun laying their new route to Uddingstone, *viâ* Bothwell, from Hamilton.

LEEDS: *Engineer Volunteers.*—Information has been received by the commanding officers of the 2nd West Yorkshire Royal Engineers (Volunteers) that the Army Council have allotted to Leeds an air-line cable company and a wireless telegraph company, which will consist in the aggregate of 18 officers and 500 men.

Tramway Receipts.—The total receipts upon the municipal tramway system for the 51 weeks to March 21st were £328,475, an increase of £12,782 over the figures for the corresponding period of the previous financial year.

LIVERPOOL: *Tramway Report.*—The annual report of the Tramways Manager has been issued, and shows that the number of passengers carried during 1907 amounted to 124,043,239, the receipts to £572,822, and the mileage to 12,231,799. The average earnings per car-mile were 11·24d., an increase of 0·07d. over the earnings of 1906. The traffic receipts and car-mile earnings, together with the number of passengers carried, are the highest recorded in connection with the Liverpool tramways undertaking.

Digitized by Google

LONDON: *London County Council.*—At the meeting on Tuesday the London County Council sanctioned the borrowing by Marylebone Borough Council of £31,306 for electric lighting purposes.

On a report of the Finance Committee submitting the annual estimates, a discussion took place as to the amount allowed for tramway work, viz., one and a quarter millions. Various amendments to increase the amount of the estimates were defeated, and the proposals of the Finance Committee were agreed to.

The report of the Parliamentary Committee, recommending the Council to continue its opposition to the London and District Electricity Supply Bill, the London Electric Supply Bill, and the London (Westminster and Kensington) Electric Supply Companies Bill, was adopted.

Hampstead: Street Boxes.—At the last meeting, the Borough Council agreed to support Islington in their appeal to the L.C.C. to obtain powers to exempt electric lighting service boxes from the provisions of Section 145 of the London Building Act, 1894, the effect of which Section is to entitle the District Surveyor to fees in respect of their construction.

Marylebone.—At the last meeting of the Borough Council, it was stated that the receipts of the electrical undertaking during the past year had fallen short of the estimates by £4,520. This result was attributed to reductions in the price, increased price of coal, &c.

MANCHESTER: *Tramway Sick Fund.*—The Tramways Committee have decided that they cannot comply with the tramway workers' request for help from the public funds towards their sick and benefit society, the Committee having adopted the following resolution :—"That having fully considered the General Manager's reports as to the formation of a sick and benefit society for the employees of this department, we are unable to adopt the suggestions contained in such report as to the subsidising of the finances of such a society from the fund of the tramways department," point out that the thritt fund, which is open to all Corporation servants receiving more than 30s. per week, is supported by the funds of the Corporation.

MARLBOROUGH: *Electric Lighting Order Revoked.*—The Board of Trade has revoked the Electric Lighting Order granted in 1905.

MIDDLESEX: *Tramway Finances.*—The recommendations of the Light Railways and Tramways Committee regarding the accounts of the Metropolitan Electric Tramways, Ltd., which were adjourned by the County Council at its February meeting (ELECTRICAL ENGINEERING, March 5th, p. 368), were again considered on March 26th. It was agreed to pay to the company £422 2s. 9d., being interest for 1905, at 4 per cent., upon the company's expenditure on light railway depôt sites; that the £500 a year proposed to be charged by the County Council as regards light railways in respect of rent, rates, cleaning, lighting, warming, salaries (clerks' department), and office expenses, for 1906 and 1907 be charged against the Council's capital expenditure, upon which the company pay interest, and that for 1908 and onwards £500 a year be paid to the Council by the company and charged to revenue; and that a joint reserve fund be created out of revenue for the purpose of the reconstruction and renewal of the light railways and tramways tracks in the future, subject to the fund being invested in the joint names of the County Council and the company, without earmarking it as between tramways and light railways, and that the fund only be drawn on for reconstruction and renewal of tracks with the consent of the County Council. The Council also agreed that the stock now representing the £20,000 deposited by the company, in accordance with agreement, and any amounts representing the invested dividends on the stock, be released, and that this amount, together with £3,471, representing £3,993 of consolidated stock, to be paid over by the company and invested in the joint names, be made to form the nucleus of the reserve fund, to be added to out of revenue, but that the amount of stock referred to above be primarily held as security for the performance by the company of their obligations under agreement of November, 1900, up to the grant of the lease of all the light railways. Any part of the reserve fund not expended at the end of the lease is to be divided in agreed proportions of 45 per cent. to the County Council, and 55 per cent. to the lessee company, and the dividends received in respect of the reserve fund are to be invested from time to time in the joint names, and be added to the reserve fund.

MINSTER-ON-SEA: *Tramways.*—A committee has been formed to arrange for an application to the Light Railways Commissioners for an extension of the Sheerness tramways to Minster-on-Sea.

NEWCASTLE: *Tramway Extensions.*—A deputation from the Newburn Urban District Council recently waited upon the Tramways Committee of the Newcastle Corporation with the request that the Newcastle tramway system should be extended to Newburn.

Street Lighting.—The Tramways Manager and the Lamps Inspector have issued a report dealing with the lighting of Jesmond Road, North Road, and Osborne Road with alternate lamps, together with the cost of removing the lamps which are to be dispensed with. The difference in the cost of lighting by flame arc lamps in Westage Road was also dealt with. There are 100 centre pole lamps and 50 side pole lamps in the streets mentioned, and the cost of removing 50 centre pole lamps and 25 side pole lamps and fixing them elsewhere is estimated at £721. In discussing this proposition, the officials point out that as all the lamps left will be on one circuit, there will be a greater risk of the streets being left in total darkness, a circumstance which cannot take place at present. The report goes on to state that the experiments in Westgate Road have clearly demonstrated that the original Brockie-Pell arc lamps are inferior to flame arc lamps as a lighting medium for public streets. If flame arcs are adopted, the annual cost will be £12 each, and the total cost for lighting Westgate Road with 20 lamps will be £240, as against £180 for enclosed arc lamps. The report anticipates that before long makers of flame arc lamps will be able to place upon the market a carbon which will materially reduce the annual cost.

PERTH: *Tramway Employees' Social.*—The annual social and dance of the employees of the tramway department was held in the Masonic Hall, Perth, last week, the Governor of the Tramways Committee presiding. During the course of the proceedings the Convener made an appreciative reference to the manager of the tramways, Mr. Lambert, who, he said, had not only invented a folding step, but also a magnetic brake.

PORT GLASGOW: *Electricity Supply.*—Negotiations have been carried on between the Greenock Corporation and the Port Glasgow Town Council, with regard to a supply of electricity. The Greenock Corporation proposes to lay the necessary high-tension transmission cables, and establish a low-tension supply, the whole expenditure to be borne by Greenock, except in special cases of large demands, when the supply shall be the subject of a special agreement. The option is given to the Port Glasgow Council to purchase the whole undertaking at the end of 28 years. The recommendation of the Electricity Committee that the Council should approve generally of the above agreement has been confirmed by the Corporation, subject to the following additions :—(1) the charge to be the same as to Greenock consumers; (2) any deficit to be met by Greenock; (3) that the Greenock Corporation have no power to assess in Port Glasgow for any deficit.

POTTERIES DISTRICT: *Tramway Ambulance Corps.*—The fourth annual dinner of the Potteries Electric Traction Company's division of the North Staffordshire Corps of the St. John's Ambulance Brigade was held at Stoke last week.

RAWMARSH: *Dolter Surface Contact System.*—As a result of a conference between the Mexborough, Swinton, and Rawmarsh Urban District Council, referred to in our last issue, it is stated that the Manager of the tramways company can give no undertaking that the Dolter system can be run more satisfactorily than it is at present. The conference was favourably inclined to accept a proposition that the overhead system should be substituted, the two courses offered by the company being to improve the present system at a cost of £3,000, or to substitute the trolley system at a cost of between £6,000 and £8,000. A resolution was passed that in the event of the tramway company installing the overhead system, it would be desirable to allow the company to defer the payment of rents for the first three years, provided the whole of the rent be paid up within the stipulated period of seven years.

SUNDERLAND: *Supply to Sir James Laing & Sons.*—Satisfactory arrangements have now been made between Sir J. Laing & Sons and the Corporation, by which the supply of electrical energy to the firm's works has been resumed. It will be remembered that a short while ago, in consequence of the voluntary liquidation of Sir J. Laing & Sons, and the fact that the Corporation were not allowed to rank as preferential creditors, the supply was cut off.

SOUTH SHIELDS: *Tramway Manager.*—At an adjourned meeting of the Town Council last week, a recommendation of the Tramways Committee to give the tramway manager a three months' notice to terminate his engagement in the event of his not tendering his resignation was passed. A new manager is to be advertised for at a salary of £250 per annum.

SHANGHAI: *Opening of Tramways.*—The Shanghai Electric Tramways Co. inaugurated its service on March 5th.

TASMANIA: *Electric Winding.*—The Mount Lyell Mining & Railway Co. is installing an Ilgner electric winding plant at the North Lyell Mine.

TUNIS: *Electric Lighting.*—A company under the title of La Compagnie Electrique de Bizerte has been formed to carry out an electric lighting scheme at Bizerta.

WALSALL: *Workhouse Lighting.*—The Building Committee recommend that no action be taken with regard to the proposed electrical installation in the workhouse, on the ground that the cost would be excessive.

WREXHAM: *Electricity Undertaking.*—At the last meeting of the Corporation, when the rates for the ensuing year were fixed, it was stated that for the first time in its history the electric light undertaking called for no aid from the rates, whilst it was estimated that next year would see a credit balance equal to a penny rate.

YARDLEY: *Tramways.*—Arrangements in connection with the agreement between the Council and the British Electric Traction Co., for working the tramways, are nearly completed

Digitized by Google

TENDERS INVITED AND PROSPECTIVE BUSINESS

DERBY.—The Electric Lighting Committee estimate that £7,500 will be required for capital expenditure during the coming financial year, and recommend that application be made to the Local Government Board for sanction to borrow this sum.

IRELAND.—At the present time five towns—Fermoy, Enniscorthy, Newcastle, County Down, Templemore, and Warrenpoint—are interested in electric lighting schemes, the matter being in the hands of the local authorities of each place.

LIMERICK.—Tenders are invited for a supply during the year ending March 31st, 1909, of accumulator accessories, cable, electrical stores, engine-room stores, mains accessories, meters, &c. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by April 10th.

LONDON: *Poplar.*—The Electricity Committee invite tenders for the erection of a sub-station building at Millwall in brick, ferro-concrete, or corrugated iron. Full particulars from the Borough Electrical Engineer, fee 5s., not returnable, and tenders to the Town Clerk by April 29th.

METROPOLITAN ASYLUM BOARD.—Tenders are invited for the installation of electric lighting at the South Western Hospital and Ambulance Station, Landor Road, Stockwell, S.W. Full particulars from Mr. W. H. Hatch, Engineer-in-Chief to the Board (fee £2 2s. returnable), and tenders to the Clerk by April 15th.

NETHERLANDS.—The *Bulletin Commercial* (Brussels) of March 7th reports announcements in the Dutch press to the effect that the Communal Council of Gouda have granted a provisional concession to Mr. J. H. Müller, of The Hague, for the construction and working of tramway lines between Gouda and Schoonhoven, Gouda and Oudenwater, and Gouda and Rotterdam; and that the Communal Council of Kampen offers a subsidy, without interest, of 495,000 florins (about £41,250) for the construction of a tramway between Hatten and Kampen

RHYL.—Tenders are invited for the wiring, &c., for electric lighting of the new promenade gardens. Full particulars from the Engineer, Electricity Works, Rhyl, and tenders to the Town Clerk by April 9th.

SPAIN.—The *Gaceta de Madrid* of March 15th announces a public competition for the establishment of inter-urban telephonic communication between Las Palmas and Arucas, in the island of Gran Canaria. Sealed tenders must be presented, within 30 days from the date of publication in the *Gaceta*, either at the Civil Administration of the Canaries, or at the Registry of the Dirección General de Telégrafos, Calle de Carretas 10, Madrid. The *Gaceta*, containing the conditions of contract and model form of tender, may be consulted by British firms on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C. The same *Gaceta* notifies that the Compañia Elétrica Madrileña de Tracción has applied for a concession for an electric tramway in Madrid, and that a period of one month has been appointed for the presentation at the Dirección General de Obras Públicas, Madrid, of propositions in terms more favourable to the Government.

WALLASEY.—Tenders are invited for the supply of automatic overload and reverse current single-pole circuit-breakers. Particulars from the Engineer and Manager, and tenders to the Town Clerk by April 15th. The Council also invite tenders for the supply of stores during the ensuing twelve months, including switches and cut-outs, meters, cable, and junction boxes, and arc lamp carbons.

WATFORD.—A report by the Electricity Sub-Committee recommends that, subject to sanction by the Local Government Board, tenders should be invited for a high-speed engine, 150 kw. alternator, exciter, and accessories. The question of installing an additional 500 kw. turbo-generator, it is suggested, should be deferred until January next year.

WIMBLEDON.—A Local Government Board inquiry was held last week into the application by the Corporation to borrow £17,600 for additional machinery at the generating station, and £3,600 for a switchboard. There was a good deal of opposition.

TENDERS RECEIVED AND ACCEPTED

ASTON MANOR.—About twenty tenders have been received for the extensions of buildings at the generating station, ranging from £4,737 to £5,600.

AUSTRALIA: *Queensland.*—The tender of Messrs. W. T. Henley's Telegraph Co., Ltd., has been accepted for the supply and delivery at Brisbane of the following:—880 yards 208 cable pair, 12½ lb. conductor, £630; 2,860 yards 104 cable pair, 12½ lb. conductor, £360; 320 yards 78 cable pair, 20 lb. conductor, £380; 3,941 yards 52 cable pair, 20 lb. conductor, £285; 440 yards 39 cable pair, 20 lb. conductor, £245; 880 yards 26 cable pair, 20 lb. conductor, £180; 440 yards 13 cable pair, 20 lb. conductor, £115; 880 yards 2 cable pair, 20 lb. conductor, £25.

FINCHLEY.—The District Council has accepted the tender of Messrs. Browett, Lindley & Co., Manchester, at £4,528, to supply a 700-kw. engine and dynamo, and carry out the necessary work of installation.

FRANCO-BRITISH EXHIBITION.—It is stated that a Southampton firm has obtained the contract for an electric lighting installation in the great Stadium.

LONDON: *London County Council.*—In connection with the reconstruction of the tramways from Brixton to Camberwell, the Highways Committee recommend the acceptance of the tender of Mr. W. Manders, of Leyton, for the roadwork, &c., at £19,276 8s. Permission will be granted for sub-letting the supply bonds to the Lahmeyer Electrical Company, Limited, Hadfield's Steel Foundry Company, Limited, the supply of the drain-boxes; and to Bayliss, Jones and Bayliss, Limited, the supply of the tiebars, bolts, &c.

The following tenders have been received for the supply of cables in connection with the tramway works to be undertaken during 1908-9:—(1) Tenders for high-tension electric cables, &c.: The British Insulated and Helsby Cables, Ltd., £32,000 3s. 11d.; Siemens Brothers & Co., Ltd., £32,487 4s. 10d.; The Western Electric Company, £32,580 14s. 8d.; Callender's Cable and Construction Company, Ltd., £32,918 16s. 2d.; W. T. Henley's Telegraph Works Company, Ltd., £33,292 13s.; W. T. Glover & Co., Ltd., £33,648 15s. 7d.; Johnson & Phillips, Ltd., £33,922 10s. 8d. (2) Tenders for low-tension electric cables and telephone cables, &c.: W. T. Henley's Telegraph Works Company, Ltd., £35,101 4s. 7d.; The Union Cable Company, Ltd., £36,085 2s. 2d.; The British Insulated and Helsby Cables, Ltd., £36,349 9s. 10d.; Siemens Brothers & Co., Ltd., £36,918 11s 1d.; Johnson & Phillips, Ltd., £36,955 11s. 8d.; The Western Electric Company, Ltd., £37,050; W. T. Glover & Co. Ltd., £38,546 13s. 6d.; Callender's Cable & Construction Company, Ltd., £38,745 11s. 3d.

The tender of the British Insulated & Helsby Cables, Ltd., has been accepted for the high-tension cables, and that of W. T. Henley's Telegraph Works Co., Ltd., for the low-tension cables.

The tender of Messrs. John Spencer, Ltd., has been accepted for the supply of steam, exhaust, feed, drain and condenser piping and valves, water tanks, &c., required for the second portion of the Greenwich generating station at £10,910 13s. 10d.

The tenders of the Frodingham Iron & Steel Co., Ltd., for the supply of slot and conductor rails, and of Hadfield's Steel Foundry Co., Ltd., for the supply of special trackwork, were extended to include £2,633 0s. 10d. for slot rails, and £5,283 for special work in connection with electrification of the tramways in Queen's-road, Battersea.

For the installation of electric lighting at the Hackney Downs Secondary School the tender of W. G. Cannon & Sons, Ltd., at £249 10s. was accepted.

Hampstead.—The Borough Council has accepted the following tenders for supplies to the Electricity Department:—Dynamo and Belliss crank chamber oil, A. Duckham and Co., three years' supply; cylinder oil for superheated steam, Vacuum Oil Co., Ltd., three years; crank-chamber oil for Willans engines, Bowring Petroleum Co., Ltd., one year.

Hammersmith.—The Borough Council has accepted the following annual tenders:—Supply of meters: Messrs. Ferranti, Ltd., 110 volts, 3 amp., £1 12s. 6d.; 5 amp., £1 12s. 6d.; 10 amp., £1 12s. 6d.; 25 amp., £1 15s. 6d.; 50 amp., £2 4s.; 75 amp., £2 11s. 6d.; 100 amp., £2 19s.; 250 amp., £5 15s.; 500 amp., £7 2s.; 2½ per cent. discount; 220 volts, 3 amp., £1 12s. 6d.; 3 amp., £1 12s. 6d.; 10 amp., £1 12s. 6d.; 25 amp., £1 15s. 6d.; 50 amp., £2 4s.; 75 amp., £2 11s. 6d.; 100 amp., £2 19s.; 250 amp., £5 15s.; 500 amp., £7 2s.; 2½ per cent. discount; 3,500 yards 0·1 E.H.T. cable, Western Electric Co., £690; 700 yards, 0·05 H.T. cable, do., £35; 750 yards 0·023 H.T. cable, do., £50 4s.; 500 yards 7/18 twin, do., £43 16s. 3d.; 500 yards 0·25 E.H.T. cable, do., £180 13s. 6d.; motors, dynamos, &c., for Messrs. Gwynnes, Ltd., British Thomson-Houston Co., Ltd., £1,638 10s.

Woolwich.—The Borough Council has placed an order with the

Digitized by Google

Patent Enamel Co. for 50 enamelled advertisement plates, at £29 7s. 6d., for use in advertising the electricity supply.

METROPOLITAN ASYLUMS BOARD.—The Board has accepted, at £23 11s. 6d., the tender of Veritys, Ltd., for fittings to prevent unauthorised interchange of electric lamps.

WATFORD.—A tender by Messrs. Ferranti, Ltd., for the supply of two high-tension fuse-boards at £52 15s. each has been referred to a Sub-Committee.

Annual Convention of the American Institute of Electrical Engineers.—It has been decided that the Annual Convention of the American Institute of Electrical Engineers will be held at Atlantic City, from June 29th to July 2nd.

Accident in a Mine.—A miner, who was putting corrugated iron sheeting over a wooden casing which contained a 500-volt electric cable in the underground workings of the Francis Pit, Dysart, Fife, drove a nail into the cable and received a fatal shock.

The North-west London Tube.—A private meeting of property owners and agents, representing land and houses to the value of several millions sterling, was held at Kilburn on Thursday last, and a committee was appointed to direct a movement for the presentation of a petition from the residents of the district to the promoters of the North-west London Railway, who hold statutory powers for the construction of a tube railway from Victoria to Cricklewood, via Marble Arch. The intention of the committee is to arouse public interest, in order that the commencement of the line shall not be further delayed.

Electrical Power in Ontario.—In the Ontario Legislature, Toronto, last month, Premier Whitney, in answer to questions addressed to the Government, stated that the Government had been approached with regard to the purchase of the plant and transmission lines of the Electrical Development Company, but that in consideration of the practically accepted contract with the Ontario Power Company, they had declined to consider the proposition. The purchase would also have involved a liability of upwards of five million pounds sterling, which was too great.

Creosoted Wood for Tramway Tracks.—In the Court of Appeal on Friday last, the Lord Chief Justice, Sir Gorell Barnes, and Lord Justice Farwell had before them the case of West *v.* The Bristol Tramways Co., on the appeal of the defendants from the judgment of the Divisional Court (see ELECTRICAL ENGINEERING, February 6th, 1908, p. 220). The Lord Chief Justice, in delivering judgment, said that although there was an obligation on the defendants to use wood pavement, there was no obligation to use wood pavement which was dangerous to property, and the jury had found that the injury to the plaintiff's plants was caused by the creosoted wood paving. He came to the conclusion that the contention that the plaintiff had no common law right of action failed, and that the contention that the special Act authorised what the defendants had done also failed. The appeal was therefore dismissed.

North Metropolitan Tramways Co. v. Leyton Urban District Council.—In the Appeal Court last week, the North Metropolitan Tramways Co. appealed against the decision of Mr. Justice Phillimore and Mr. Justice Walton, last October, with regard to the acquisition by the Leyton Urban District Council of so much of the company's undertaking as was within its area. Mr. Graham Harris awarded the Company compensation for the whole of their undertaking in Leyton, but held that a car-repairing factory and land comprising a total area of 77,000 square feet were not suitable or used for the purposes of tramways within the area of the Council, being a factory where the Company repaired and constructed cars for the whole of their system. He accordingly declined to make any allowance in his award for the works and land in question. The Company appealed against this decision, and sought to have the award set aside. The Court held that the local authority were not compelled to take the car factory. The Lord Chief Justice now stated he was satisfied that substantial justice had been done by the award of Mr. Harris, and the appeal was dismissed.

Proposed Alterations in the American National Electric Code.—Some alterations in the American National electric code have been suggested by a committee of the Underwriters' National Electric Association, and are under consideration. According to the *Electrical World* (New York), the recommendations of the committee on rheostats do not cover construction and installation of automatic apparatus, but consist in amendments to rules dealing with the construction of rheostats. The amended rules, if adopted, will call for resistances so constructed that if the conductor be fused, the arc or attendant flame shall be confined within the rheostat. The committee on transformers has recommended the adoption of new rules covering the installation of transformers on low potential systems. A complete set of rules is proposed covering the wiring of electric cranes, and also a set of rules governing the construction and testing of circuit breakers. In order that there may be no dispute regarding the wiring of varying speed alternating-current motors, motors of this type will be required to be marked with the maximum current which they can safely carry for thirty minutes, starting cold. The report of the committee on switches and cut-outs has to do chiefly with rules governing the construction of panel boards and cabinets.

MISCELLANEOUS CITY NOTES

BRITISH WESTINGHOUSE ELECTRIC AND MANUFACTURING CO.—Applications are invited before the 8th inst. for an issue of £250,000 six per cent. prior lien debentures in £100 shares, redeemable by means of an annual sinking fund of 2 per cent. (with power for the company to increase the same at any time) to be applied annually in purchasing debentures in the market at not exceeding par (exclusive of accrued interest), or in redeeming debentures to be selected by drawings, the first redemption being on January 1st, 1909. Any debentures not previously redeemed will be repayable at par on January 1st, 1933, or on the security constituted by the trust deed becoming enforceable.

MEXICO ELECTRIC TRAMWAYS.—An application was made in the Chancery Division on Wednesday last week for the appointment of a receiver to this company. It appears that a lease has been granted of the company's undertaking to the Mexican Consolidated Electric Co., which certain shareholders regard as a device for depriving them of certain dividends upon their shares. An action is pending as to the legality of the lease in question, and after hearing evidence and arguments, the parties in the present action agreed that pending the action yet to be heard, there should be no completion of the lease.

ROBEY & CO.—Mr. William Embleton-Fox, of Northorpe Hall, Lincoln, has joined the board.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—The warrants for payment of interest due on April 1st on the 4½ per cent. first mortgage debenture stock of this company have been posted.

UNITED RIVER PLATE TELEPHONE CO.—In a circular issued by the directors, it is stated that an issue of 20,000 ordinary shares of £5 each is to be offered to present shareholders. The extra capital is required for the general development of the company's undertaking, especially in connection with placing the company's lines in the city of Buenos Ayres underground. Sir J. Gavey last year visited Argentina with a view to making an examination of the company's affairs, and his report is entirely favourable to the proposed issue.

Electrical Engineers Volunteers (London Division).—Mr. F. M. Masters has been given a second lieutenancy.

Serious Accident in Germany.—A large dynamo, which was being tested in the presence of several engineers and a number of workmen in the Siemens-Schuckert Works at Charlottenburg, suddenly flew to pieces. The building in which the machine was being tested was completely wrecked. Three men were killed and fifteen seriously injured.

Excessive Speed of an "Electrobus."—The driver of an electric omnibus was summoned at Marylebone last week for exceeding the speed limit in the High Road, Kilburn. It was stated that the omnibus was timed over a measured furlong, and covered this distance at a speed of over 16 miles an hour. The traffic manager to the Electrobus Company, however, stated that the company had eleven omnibuses running, and informed the magistrate that the 'buses were unable to travel at a speed exceeding 12 miles an hour unless running free-wheel, and he was prepared to call expert evidence to prove this if an adjournment could be granted. Mr. Paul Taylor did not think this worth while, and fined the driver 10s. and 2s. costs.

Telegraph Traffic.—The Alexandra-Larnaca cable is still down, as are also the cables between Paramaribo and Cayenne, and between Guadeloupe, Antigua, and Dominica. Neither have we yet been advised of the repair of the cable between Guantanamo (Cuba) and Mole St. Nicholas (Hayti). Interruptions have again occurred to the routes via Hanekin and Fao, which were speedily put right. The question of a system of Imperial cables has again been taken up by the daily Press, and the Ottawa Board of Trade have issued a pamphlet on the subject. Not only will the scheme voiced provide duplicate routes to all the chief Colonial possessions, but also means of communication at a cheap rate.

Disclosure of a Secret Process.—In the King's Bench Division of the High Court, on Thursday last, the case of the London Electron Works Co., Ltd., *v.* Wagner was heard by Mr. Justice Ridley and a special jury. The company sought an injunction to restrain the defendant, who had been in their employ, from committing a breach of an agreement by which he had undertaken not to enter into a similar business in England and not to disclose any knowledge he should obtain of their secret process. The process in question was an electrical method of recovering the tin from old tinned iron articles. The company, which had a capital of £40,000, dealt with about 15,000 tons of tinned metal each year, out of which about 2 per cent. of pure tin was obtained. In November, 1905, the defendant entered into the employ of the company, but in 1907 the company gave the defendant one month's notice to terminate the agreement, as they were suspicious of his intentions. In April, 1907, a description of the process appeared in a German electrotechnical journal, and the company contend that the information was supplied by the defendant. The defendant denied any breach of the agreement, but gave the undertaking asked for. Each party paid their own costs.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £61 10s. to £62 per ton (last week, £61 5s. to £61 15s. per ton).

AGENCY.—Mr. P. F. Brittain, of 110 Cannon Street, has been appointed sole selling agent in England, Wales, and Ireland for the Universal Electric Manufacturing Co., whose works are at Peckham, for the sale of their switchboards, fuse-carriers, cable sockets, iron-clad switches, fuse-boxes, feeder pillars, fuse-clips, resistances, choking coils, street-lighting brackets, street boxes, fuse-boards, heavy-duty switch fuses, regulating switches, &c.

LIQUIDATIONS, BANKRUPTCIES, &c.—A general meeting of the London & Continental Electric Carriage Co. will be held at South Sea House, Threadneedle Street, London, E.C., on April 23rd, at 12 noon, for the purpose of hearing the liquidator's account of the winding up.

It has been decided to voluntarily wind up the Standard Wire Co., of Sowerby Bridge, Yorkshire. Mr. W. H. Armitage, Halifax, has been appointed liquidator.

Creditors of the York Electric Co., Ltd., are requested to send in particulars of their debts or claims, together with the names and addresses of their solicitors, to the liquidator, Mr. C. A. Rymer, Bank Chambers, Nessgate, York, by April 11th.

A meeting will be held at the offices of the liquidator on April 29th at 2 p.m. to hear the liquidator's account of the winding up.

The trustee in the bankruptcy of Mr. K. C. Moran, electrical engineer, 80A Teddesley Street, Walsall, has been released.

The trustee in the bankruptcy of C. W. Stafford, Electrical Engineer, 59 Toll End Road, Ocker Hill, Tipton, Staffs, has been released.

Notice is given in the *London Gazette* of a meeting of Messrs. Ferranti, Ltd., at the offices of Mr. J. M. Henderson, the liquidator, 2 Moorgate Street Buildings, London, on April 27th, at 12 noon. This, of course, refers to the old firm, before the reconstruction in 1901.

A meeting of the Chatham, Rochester & District Electric Lighting Co., Ltd. will be held at 22 High Street, Chatham, on May 1st at 4 p.m. to hear the liquidator's account of the winding up.

A meeting of the Britannia Electric Lamp Co. will be held at the offices of Messrs. James Worley & Son, 37 Lime Street, London, on April 29th at 2 p.m. to receive the liquidator's account of the winding up.

A meeting of the creditors of Messrs. Bruce Peebles & Co. was held in London on Thursday, when Mr. Tait stated that if there was a forced liquidation, he calculated that the unsecured creditors would only receive 6s. 6d. in the £, and that this would not be distributed for a considerable time. A committee of creditors was appointed to consider a scheme put forward by the directors as follows: That the debentures should be extended for ten years, that the interest should remain, as at present, at 5 per cent., with a sinking fund of 2 per cent. per annum; that the trade creditors should accept 7s. 6d. in the pound in a debenture which would be redeemed by the proceeds of the sale of securities and the collection of contract balances, and this 7s. 6d., he considered, should be paid in a short time. The other 12s. 6d. would be given the creditors in the shape of a cumulative 6 per cent. preference share in the new undertaking. Altogether 120,000 cumulative preference shares would be issued, of which 30,000 would be offered at par to the shareholders for subscription, and that would provide £30,000 for working capital and for redeeming debentures. The deficiency has been estimated at £163,086.

The Removal of Snow from Tramway Tracks.—An action has been brought by the Acton Urban District Council against the London United Tramways Co. to recover £20, the cost of removing snow from the margin of the main road, cast there by the action of the tramway company's snow plough. They also claimed damages under the Tramways and Public Health Acts for a nuisance and obstruction. The tramway company stated in defence that they were only obliged to keep the track in proper repair, and were not obliged to remove snow. At Brentford County Court, Judge Howland Roberts said that the tramway company was not obliged to remove snow, but that an obstruction had been caused, and judgment was given for the plaintiffs for the amount of £25 damages and costs.

Damages against the Gt. Northern, Piccadilly, & Brompton Railway Co.—At Clerkenwell last week an engineer's assistant named W. W. Johnson, and his wife, sued the Gt. Northern, Piccadilly & Brompton Railway Company for damages for alleged negligence on the part of the company's employees. As the train in which the plaintiffs were travelling ran into Gillespie Road Station, it was said to have been pulled up with a sudden and violent jerk, with the result that the plaintiffs, who were standing up, were thrown to the floor of the car, and Mrs Johnson was rendered unconscious. The jury awarded £20 damages.

PARLIAMENTARY INTELLIGENCE

DUBLIN AND CENTRAL IRELAND ELECTRIC POWER BILL.—Our report of the proceedings in connection with this Bill before a House of Commons Committee is given on p. 503.

FINCHLEY URBAN DISTRICT COUNCIL BILL.—This Bill, which provides for a small extension of the boundaries to which electric supply will be extended, was read a third time in the House of Commons on Monday, having been passed by a Committee last week.

KING'S COLLEGE, LONDON (TRANSFER), BILL.—This Bill was sent forward for third reading by the Unopposed Committee of the House of Lords last week. The object of the Bill is to transfer to the University of London the powers and duties of King's College, London, in relation to instruction of a university standard in subjects comprised within the faculties of the University other than the faculty of theology.

LONDON AND WINDSOR MOTOR ROADS BILL.—It is announced that the London and Windsor Motor Roads, Tramroads and Tramways Bill, will not be further proceeded with this session.

METROPOLITAN ELECTRIC TRAMWAYS BILL.—A Committee of the House of Lords, presided over by Lord Wenlock, considered this Bill on Wednesday last week. The object of the Bill is to revive the capital powers which the company obtained in 1901 in connection with the Harrow Road and Paddington tramways, and also in connection with the extensions of the line to Edgware Road. The Willesden Urban District Council opposed the Bill in an endeavour to secure halfpenny half-mile stages, which the company said was commercially impossible. There was also an objection by a jobmaster on the route, who asked that the whole of his property should be taken, and not a portion. The preamble of the Bill was declared passed, and both oppositions were unsuccessful.

MOTHERWELL CORPORATION BILL.—This Bill, which was before a Committee of the House of Commons last week, was reported for a third reading on Friday. Particulars were given in our last issue.

PROGRESS OF ELECTRICAL BILLS.—In the House of Commons last week, the London County Council Tramways and Improvements Bill was read a third time.

SOUTH WALES ELECTRICAL POWER DISTRIBUTION BILL.—The House of Lords Committee presided over by Lord Wenlock, decided, on Wednesday last week, to allow this Bill to proceed, subject to one or two adjustments on the question of the area to be supplied by the Freforest Electrical Consumers Co. We gave full particulars of the Bill and the opposition to it in our last issue.

TRAMWAYS ORDER CONFIRMATION (No. 1) BILL.—This Bill, which was read a third time in the House of Lords last week, relates to a Provisional Order granted by the Board of Trade under the Tramways Acts to the Manchester Corporation for three short lengths of tramway in the Moss Side district. There are two pieces of double-track, respectively 8·89 chains and 0·67 chains, and a connecting link of single track 0·55 chains long.

WISHAW ELECTRICITY BILL.—This Bill was reported for third reading by the Unopposed Committee of the House of Commons on Thursday. It provides for the expenditure of money in supplying electrical fittings, &c., and makes provision with regard to stand-by supply and discounts.

WOLVERHAMPTON CORPORATION BILL.—The Police and Sanitary Committee of the House of Commons, presided over by Mr. Corrie Grant, had this Bill under consideration last week, when it was ordered to be reported for third reading. Mr. Ram, K.C., and Mr. Jeeves appeared for the Bill, to which there was no opposition. Amongst the proposals in the Bill was one relating to tramways, extending the time granted by the Act of 1904 for the reconstruction and improvement of Rookery Bridge and for the construction of tramways in connection therewith for three years. The proposed new tramways will join up with the busiest part of Wolverhampton, negotiations for the acquisition of the necessary property having just been concluded. At the other end of the line there is a rapid development going on which has justified the Corporation in reviving the powers in question.

APPOINTMENTS AND PERSONAL NOTES

Mr. C. C. Butler, the first assistant in the Willesden Electricity Department, has been promoted from the second to first-class division at a salary of £160, rising by annual increments of £10 to a maximum of £200, and the salary of Mr. L. T. Bickell, Mains Superintendent, has been increased from £104 to £111 10s., rising by annual increments of £7 10s. per annum to a maximum of £134.

The Stoke Newington Borough Council has increased the salary of the Electrical Superintendent, Mr. S. Hann, from £150 to £175 per year, and the salaries of Messrs. L. Andrew and H. Large, assistants, have been advanced respectively from £91 to £104 a year, and from £65 to £78 a year.

The Stepney Borough Council has raised the maximum salary of Mr. E. E. Dorking, senior analyst and prime cost clerk to the electricity supply department, from £135 to £140 per annum.

According to the *Review of the River Plate*, Mr. J. T.

Digitized by Google

Cornish, Chief Engineer to the six associated tramway companies of the Grand National group, has been appointed Chief Engineer to the City of Santos Improvements Co., Ltd. (electrical traction, lighting, and gas and water service). Mr. Cornish will pay a visit to England before taking up his new appointment.

Mr. W. P. Beatty, Chief Electrical Engineer of the Pacific Railway, has left for England in connection with the tenders for the new power house to be erected at Bahia Blanca. The total cost of the work amounts to about £250,000.

Mr. Morton Beales is severing his connection with Messrs. Bruce Peebles & Co., Ltd., and is entering into partnership with Mr. M. M. Gillespie. The new firm will be styled Gillespie & Beales, and will have offices at Amberley House, Norfolk Street, Strand, and will carry on business as buying and selling engineers, exporters, and contractors.

COMPANIES' MEETINGS AND REPORTS

ANGLO-ARGENTINE TRAMWAYS.—The report for the year ended December 31st, 1907, shows a net revenue, including £10,081 brought forward and including profits of the six months' working of the Buenos Aires and Belgrano tramway system, and allowing £65,000 for depreciation renewal fund, of £335,573. After transferring £4,200 to a sinking fund for the redemption of the preference shares and £4,030 to the investment depreciation account, a dividend of 8 per cent. is recommended on the ordinary shares, carrying forward £16,734.

BASTIAN METER.—During the six months ending December 31st, 1907, there was a net profit of £552 earned. This sum, added to the balance of profit remaining from the half-year ending June 30th, 1907, of £534, makes a total of £1,086. The directors propose the payment of 2½ years' 6 per cent. cumulative preference dividend to December 31st, 1907, and a dividend of 2½ per cent. on the ordinary shares, carrying forward £536. At the meeting recently the report was adopted.

BRITISH ELECTRIC TRANSFORMER CO.—The report for the year 1907 shows that the net trading profit has improved to the extent of about £1,800, as compared with the year 1906. For the purposes of making this comparison, allowance has been made for the sales of patents included in the 1906 account, and also for the fact that this year's account provides considerable sums for writing down stock, &c., not dealt with in the previous year. A block of £15,010 preference shares has been obtained in settlement of the debt, amounting to £10,011, the whole of which was written off last year. These preference shares the directors believe may ultimately prove of value. After writing down certain items of stock, &c., referred to above, and paying all manufacturing costs, and the expenses of administration, there remains a net trading profit of £6,248, *less* loss brought forward from last year, £3,998, making available a balance of £2,249. The Board recommend that this be allocated as follows:—To depreciation reserve, £1,300; to payment of 6 per cent. preference dividend for the six months ended December 31st, 1906, carrying forward £34. Mr. E. Phillips, who acted for several years as chairman of the company, resigned his seat on the Board on November 20th, 1907, and Mr. J. F. Albright was appointed chairman of the company. After full consideration of the various matters referred to them, a report was recently issued by the committee of shareholders approving the policy adopted by the majority of the Board. The directors are in full agreement with the further conclusions arrived at in the committee's report. The meeting will be held on the 7th inst.

BROMLEY (KENT) ELECTRIC LIGHT AND POWER.—The report for 1907 states that the lamp connections have increased from 71,222 to 77,802. The revenue from sale of current increased from £13,997 to £15,237. During the year considerable extensions have been made to the generating plant to meet the increased demand, and an additional sub-station is being erected at Elmstead. The result of the year's trading, including £313 brought forward, shows a profit of £12,386, and after payment of debenture interest and trustee's fees, amounting to £3,202, and £250 for depreciation of stock, there is a balance of £8,933. An interim dividend at the rate of 4 per cent. per annum was paid for the half-year in October, and the directors now recommend the payment of a further dividend at the rate of 7 per cent. per annum, making a total dividend of 5½ per cent. for the year, and that £4,500 be placed to reserve account, leaving a balance of £308 to be carried forward. The meeting is on April 6th.

BROWETT, LINDLEY.—The report for the year ended December 31st, 1907, shows an increased profit of £9,859. Deducting bank, debenture, and loan interest (£2,190), depreciation upon buildings, machinery, and investments (£3,859), and allocating £2,505 for upkeep of patterns, there remains a net profit of £1,318, compared with a loss for 1906. At the meeting last week the report and accounts were adopted.

CAMMELL LAIRD.—The report for 1907 states that for the first time in its history the earnings of the company do not permit of a final dividend for the year. The net profits for the year, after charging depreciation and bank and loan interest, but without interest on debenture and debenture stock, is £139,358, to which is to be added £45,952 brought forward from last year. The interest on debentures and debenture stock, the instalment of 2½ per cent. on account of dividends on paid up capital which was paid in October, and the ascertained loss on the ore and coke contracts, exceed the balance available by £14,987.

CROMER GAS.—At the ordinary general meeting of the Cromer Gas Company last week, Mr. J. Lovelace, the chairman, had some remarks to make with regard to the competition of the Corporation electric light undertaking, which, he said, was likely to be even more serious in the future than it had been in the past. To the company as ratepayers the fact that the electric lighting undertaking was not paying its way was a serious matter. This competition was extremely unfair, but he had no doubt as to the result if the company was only able to compete on fair terms.

EDWARDS AIR PUMP SYNDICATE.—The report for 1907 recommends a final dividend of 15 per cent. per annum, making 20 per cent. for the year. A further sum of £2,500 is to be placed to reserve fund for redemption of patents, bringing this fund up to £15,000, which equals the amount originally paid for patents. The reserve for dividend equalisation stands at £1,000, and the investments reserve account at £565. Of the 1,203 pumps sold during the year, 737 were for land installations, including electric lighting works, and the report further adds that the Edwards pump has now been fitted in more than 400 of the principal electric lighting and traction stations. The gross revenue for the year was £11,555, and the working expenses £4,262, leaving a gross profit of £7,293, to which is added £63 brought forward. After meeting dividends and the other amounts mentioned above, the sum of £578 is carried forward.

THE ELECTRIC LIGHTING AND TRACTION COMPANY OF AUSTRALIA.—The report for the year ended August 31st, 1907, shows that there has been capital expenditure in Australia on buildings, plant and mains incurred as follows:—On the Melbourne undertaking of £11,657, and on the Geelong undertaking of £2,526. The profit and loss account shows that the gross profit derived during the year from the two undertakings was £16,354. Adding the dividend received on the company's holding of Ordinary Shares in the Adelaide Electric Supply Company, together with interest, discounts, transfer fees, &c., the total gross profit for the year amounted to £19,741, which compares with £16,202 for the previous year. Management and general expenses at the London head office absorbed £1,971, and interest on debenture stock and sundry loans amounted to £13,361. After payment of these charges, there remains a balance to the credit of profit and loss account of £4,408, to which must be added the amount of £1,185 brought forward from the previous year, making a total credit balance of £5,593. Of this sum the directors have transferred £4,000 to reserve account, leaving £1,593 15s. 3d. to be carried forward. On August 31st, 1907, there were connected to the mains in Melbourne the equivalent of 125,974 eight c.p. lamp, whilst the total number of units sold were 1,820,879. Similar figures relating to Geelong were 44,582 and 344,501 respectively. The Adelaide Electric Supply Company, in which the company holds £127,500 ordinary shares, has continued to make satisfactory progress during the year; and a dividend of 2½ per cent. per annum on the ordinary shares was declared in December last, credit for which has been taken in this company's profit and loss account. A contract has been entered into by the Adelaide Company for the temporary supply of power to the Adelaide Municipal Tramways Trust, which is expected to prove an important source of additional revenue. The provision of the additional capital required to cope with the continued expansion of the Melbourne and Geelong undertakings is receiving the careful consideration of the directors, and they hope to be in a position to place before the shareholders at an early date a comprehensive scheme for effectually dealing with this question. The meeting will be held on the 6th inst.

FOLKESTONE ELECTRICITY SUPPLY.—The report for the year ended December 31st, 1907, states that whereas at December 31st, 1906, the equivalent of 86,871 8-c.p. lamps was being supplied, on December 31st, 1907, the equivalent of 96,500 8-c.p. lamps was being supplied. The accounts show that, including the receipts from hired installations, the profit on the revenue accounts for the three undertakings at Folkestone, Hythe, and Sandgate amounted to £12,872. This amount, with

Digitized by Google

the sum of £306 brought forward from last year's accounts, and after allowing for interest on debenture stock, dividend on preference shares, and bank charges &c., and also for the interim dividend at the rate of 4 per cent., per annum, paid on the ordinary shares, shows a balance of £5,513. Out of this the directors have carried the sum of £3,080 to the depreciation fund allocated to the various districts as follows, viz. :—Folkestone, £2,530; Hythe, £400; and Sandgate, £100; and also the sum of £350 to the reserve fund, making this fund now £2,350; and they recommend the payment of a dividend at the rate of 7 per cent. (less income tax) for the half-year (making 5½ per cent. for the year), leaving a balance of £333 to carry forward. The directors much regret the loss the company has sustained through the death of the late Mr. Alderman Baker, who was one of the pioneers of electric lighting in Folkestone, and had been associated with the company since its incorporation, and Mr. Councillor Wampach has been appointed by the directors to fill the vacant seat on the board. At the meeting last week, the report and accounts were adopted.

GATESHEAD & DISTRICT TRAMWAYS.—The report for the year 1907 shows a total revenue of £54,309, compared with £52,622 for the year 1906. Deducting working expenditure, including repairs and maintenance and interest of mortgages, and adding the balance brought forward, there remains a balance of £23,756. The directors recommend a transfer of £3,500 to depreciation and renewal account, bringing this to £15,392, to add £1,701 to the sinking fund for redemption and mortgages, £609 to depreciation and investments, and dividends of 6 per cent. and 5 per cent. on the preference shares, and 7 per cent. on the ordinary shares. The amount carried forward is £1,758. The capital expenditure during the year amounted to £532, making the total capital outlay of the company £311,977. Having regard to the bad weather experienced continually throughout the year, and the serious depression of the shipbuilding industry on the north-east coast, the directors consider the result of the year's working very satisfactory. At the meeting on Tuesday the report and accounts were adopted.

GREENOCK AND PORT GLASGOW TRAMWAYS.—The report for 1907 states that the capital expenditure during the year amounted to £517, making a total expenditure on capital account of £193,641. The total revenue for the year amounted to £34,358, and the expenditure, including interest, rents, &c., repairs, maintenance, renewals, and depreciation to £25,592. To the balance of £8,766 has to be added £136 brought forward from last account, making a total available for distribution of £8,902. It is recommended that the sum of £1,780 be carried to reserve (sinking) fund, and that a dividend of 3 per cent. per annum on the ordinary shares be paid, carrying forward £172. With the addition above mentioned, the reserve (sinking) fund stands at £11,390. There is a decrease in the receipts of £640, compared with the previous year, due to the decline in the shipbuilding trade, but as the expenditure has been reduced by £817, there is an increased profit for the year of £177. At the meeting on Tuesday the report and accounts were adopted.

GUILDFORD ELECTRIC SUPPLY.—The report for 1907 shows gross receipts of £6,466 compared with £5,975 for 1906. After crediting depreciation fund account with £1,000, there is a net balance of £3,082, compared with £2,668 for the previous year, when only £502 were credited to depreciation account. After providing for interest on debentures, dividends on preference shares, and transferring £350 to reserve, there is a net balance available for distribution of £914. A dividend of 5 per cent. on the ordinary shares is recommended, and a balance of £220 is carried forward. The number of consumers is now 588, compared with 525 last year, and the total expenditure to date amounts to £53,271. The capital issued amounts to £49,586, and in order to balance the difference, the directors propose issuing further ordinary and preference shares and the balance of the debentures.

LIVERPOOL DISTRICT LIGHTING.—At the annual meeting last week, the report and accounts given in our last issue were adopted. The company's business, the chairman stated, was increasing so rapidly that a further £5,000 new capital was necessary. Reference was also made to the satisfactory position of the undertaking in view of the effect upon the revenue of the increasing use of metallic filament lamps.

LONDON ROAD-CAR.—At the half-yearly meeting last week, Mr. J. H. Moore, M.P., who presided, dealt at some length with the increasing competition with which the omnibus proprietors now have to contend. Prior to the opening of the Central London Railway, he said the passenger traffic within a certain radius on the north side of the Thames was almost in the hands of the London General Omnibus Co., London Road Car Co., the North Metropolitan Tramways Co., the Metropolitan Railway, and the Metropolitan District Railway. Since then, however, the London County Council had converted the tramways to electric traction, and by fixing ridiculously low fares, had attracted many of the omnibus companies' passengers. Further, in the interval between the opening of the Central London Railway in 1900 and 1907, the Baker Street & Waterloo, the Great Northern & City, the Great Northern, Piccadilly, & Brompton, and the Charing Cross & Hampstead tube railways had been opened, whilst there had also been increased competition amongst the omnibus companies themselves. In spite of the fact that the wet weather of last summer had mitigated greatly against omnibuses, and thus given a favourable inclination to the tube railway receipts, the fact remained that, taking for instance the tube railways under the control of the London Underground Company, whereas £621,000 was necessary to pay 4 per cent. on the capital of £15,513,000, the actual amount earned was only £174,000 per annum.

LONDON UNITED TRAMWAYS.—The report for the year ending December 31st, 1907 shows gross receipts amounting to £545,570, and working and general expenses, maintenance, and repairs £214,672, leaving, with the balance brought forward from last account, a net revenue of £131,747. After payment of interest on debenture stock and loans and the dividend on the 5 per cent. preference shares for the year, and providing for income tax, there is a balance of £10,260. An interim dividend at the rate of 2 per cent. per annum, less income tax, amounting to £8,970, was paid in August, leaving £1,287, which the directors propose to carry forward to the next account. The gross receipts show an increase of £17,674, and the total number of passengers carried was 58,725,980, an increase of 3,570,699. The directors regret that the profits have not permitted of any appropriation to the renewal fund, which it is their desire to augment year by year. The section of the company's system in Surrey, from Raynes Park to Wimbledon and Tooting, about 6½ miles of tramway, was completed and opened for public traffic in June last. The tramway mileage now in operation consists of 55¼ miles. The company's powers in respect of certain uncompleted lines expire in August next, and application is at present before Parliament for a further extension of time and also for powers to lay a line across Kew Bridge, forming a connection between the company's main lines and Richmond. The London County Council connection with the Wimbledon lines at Tooting has not yet been effected, and the question of through running over the respective systems still remains the subject of negotiation. It is with regret that the directors have to record the fact that, owing to the exceptionally cold and wet summer season, receipts for the second half of the year's working have proved to be disappointing.

At the meeting on Friday, when Mr. C. J. Cater Scott, the chairman of the company presided, the report and accounts were adopted. Dealing with the question of physical connections between the London County Council system and their own, the chairman said that at present there were only a few yards between the two systems in the south of London, and he hoped that it would not be long before the London County Council saw their way to bring about the much-desired physical connection. Speaking of the company's Bill now before Parliament, he mentioned that having passed the Standing Orders stage in both Houses with this Bill, the company had upset the veto of both the Surrey and Middlesex County Councils, which authorities had endeavoured to prevent the Bill going forward on the question of consent. He pointed out that the local authorities in question saw fit to ask from the company the sum of £4,000 for crossing Kew Bridge, and he thought this was using the veto for a most improper purpose. The present amount for wayleaves which the company paid to local authorities already amounted to £3,600 a year, in addition to which they had had to pay for street improvements and widenings the sum of £945,991. He asked the shareholders to take these figures, together with the attitude of the local authorities, into consideration, when they would realise that it was becoming almost impossible for a company to give facilities for London traffic. Dealing with the accounts, he pointed out that the gross receipts had increased by 5 per cent., and the number of passengers carried by 6 per cent., in spite of the fact that during the year there had been twenty-four wet week-ends compared with only nine during 1906. As an instance of how the weather affected tramway undertakings, he gave the figures for the week ending July 19th, which was a fine week, when the receipts amounted to £8,473, whereas during the week ending July 5th, which was a wet week, the receipts were less by £1,242. In conclusion, the chairman mentioned that Mr. J. R. Chapman, the Chief Electrical Engineer to the Underground Electric Railways Co., of London, Ltd., had been elected a member of the Board. The total route mileage now in operation is 55½ miles.

MADRAS ELECTRIC TRAMWAYS (1904).—The report recommends a dividend of 4½ per cent. per annum on the preference shares for the half-year ended December 31st, 1907. The sum of £1,500 is placed to depreciation and renewals fund, and £221 are carried forward.

MERSEY RAILWAY. The report for the half-year ended December 31st, 1907, states that the train mileage run during the half-year was 416,189 miles as compared with 416,555 during the corresponding six months of 1906. The number of passengers conveyed during the half-year ended December 31st, 1907, has been 5,604,295, as against 5,271,524 for the correspond-

Digitized by Google

ing period of 1906, exclusive of season ticket holders. The total receipts from all sources for the half-year have been £51,027, as compared with £47,359 for the corresponding period of 1906. The working expenses, exclusive of the charges for pumping, ventilation, and litts, have been £33.205, equal to 65·07 per cent., as against £31,963, equal to 67·49 for the corresponding six months. These charges for pumping, ventilation, and hydraulic lifts for the past half-year amounted to £4,103, equal to 8·04 per cent., as compared with £3,921 0s. 2d., or at the rate of 8·28 per cent. for the corresponding period of 1906.

At the half-yearly meeting on Friday the report and accounts given in our last issue were adopted. Mr. J. Falconer, who presided, stated that the number of passengers carried had now reached the highest point since electric traction was introduced. The number carried during the past half-year was almost exactly 100 per cent. over that carried during the last half-year of steam working. He regretted that the receipts had not gone up in the same proportion, but this he thought was due to a large extent to the fact that many people who travelled first-class on steam railways now travel third-class on electric railways.

METROPOLITAN ELECTRIC TRAMWAYS.—The directors' report for the year ended December 31st, 1907, states that the total revenue for the year amounted to £297,223, including £27,476, the balance of the dividends received in the year 1906 from the North Metropolitan Tramways Company and reserved from the previous account. The directors have decided to spread this balance over the period ending June, 1910, during which the company would have continued to receive dividends from the North Metropolitan Tramways Company but for the surrender by that company of its lease of the London County Council's northern tramways. In pursuance of this policy £7,850 8s. has been brought into the present account, and the balance, £19,626, has been reserved. The traffic receipts, which amounted to £244,200, show the satisfactory increase of £64,599 over the previous year. After deducting all expenses chargeable to revenue, including £10,500 for reconstruction and renewals, and writing down preliminary expenses and other items by £6,220, there remains a surplus of £49,574, making, with the £3,791, the balance brought forward from the last account, a total of £53,365, which the directors recommend should be appropriated as follows:—Reserve fund, £5,000; dividend on preference shares, £25,000; dividend on ordinary shares at 4½ per cent. per annum, £17,610; carried forward, £5,755.

The company have discharged the balance of their liability in respect of the 3½ per cent. debentures of the North Metropolitan Tramways Company, by the payment of £51,700. The directors have, since the close of the year, issued a further £173,800 4½ per cent. debenture stock. There are now 40 miles 6 furlongs of line in operation, of which 29 miles 5 furlongs were opened prior to 1907. The company are promoting a Bill in the present Session of Parliament to authorise, *inter alia*, the construction of a tramway in the Harrow Road, from the terminus of the existing line to the Edgware Road. The London County Council have given the company notice under Section 43 of the Tramways Act, 1870, of their intention to purchase so much of the existing Harrow Road tramway as is situate within the County of London. Negotiations are proceeding with the Council as to these matters. The company have increased their holding in the North Metropolitan Electric Power Supply Company to 40,000 shares of £10 each, of which 30,000 are fully paid and the balance £5 paid. The dividend to be received in respect of this investment for the past year amounts to £12,285, being at the rate of 4 per cent. per annum on the amount paid up on these shares. The company have joined the British Electrical Federation, formed by various electrical traction and lighting companies for the purpose of co-operation and joint action in matters of common interest. The following statistics are given in the report, the figures in parentheses relate to the year 1906:—Number of passengers carried, 48,242,404 (36,318,774); number of car miles run, 5,037,204 (3,975,463); average receipts per car mile, 11·63d. (10·84d.); average receipts per passenger, 1·21d. (1·18d.); number of cars in stock, 187 (190).

Mr. E. Garcke presided at the annual meeting on Thursday, when the report and accounts were adopted. Having given some particulars of the companies in which they were interested, namely, the North Metropolitan Electric Power Supply Co., and the North Metropolitan Electric Power Distribution Co., the chairman went on to state that the Tramways Company was now working over 40 miles of tramways and light railways, the net receipts from which had increased from £134,000 in 1904 to £277,000 in 1907. The provision for renewals was larger than in the previous year, and the amount written off preliminary expenses had been doubled. To complete the whole scheme there were a further 22 miles of lines to be equipped, but it was the desire of the Board that the Middlesex County Council should not display any undue haste with regard to extensions. The feeling was that the additional capital required would be best raised by small issues of second debentures, upon which a smaller rate of interest would have to be paid than in respect of shares.

MILFORD ELECTRIC LIGHT.—At the annual meeting last week, the report and accounts were adopted. The total revenue for the year was £684, compared with £539 for the previous year, whilst the number of lamps connected were 3,527, an increase of 493. The total units sold were 43,250. After payment of debenture interest and all other charges, there remains a balance of £348, out of which a 4 per cent. dividend is paid upon the ordinary shares and small amounts placed to depreciation account and preliminary expenses.

RANDFONTEIN ESTATES.—At the annual meeting in Johannesburg, on February 7th, Mr. J. W. S. Langermann, who presided, stated that capital expenditure to the extent of £151,500 was to be incurred in connection with an additional cyanide plant, together with an electric power station in connection with it.

ROTHESAY TRAMWAYS.—The report for 1907 shows a total expenditure of £141,421. The total revenue for the year was £11,051, and after deducting all expenses chargeable to revenue, including £2,864 for debenture and other interest, and after setting aside £1,000 to renewals, sinking fund, and general depreciation and reserve, there remains a balance of £1,086, in addition to £325 brought forward from last account. A dividend of 2 per cent. on the ordinary shares is recommended, carrying forward £133.

WILLANS & ROBINSON.—The report for the half-year ended December 31st, 1907, states that as regards Rugby, after writing off £6,711 as depreciation, there is a profit of £22,946. As regards Queen's Ferry, there is a net loss (after contributing to debenture interest and to the directors' salaries) of £3,128. The net profit for the half-year is, therefore, £19,817, and the total amount available for distribution or otherwise, including £2,708 brought forward, is £22,526. The directors propose to pay a dividend at the rate of 6 per cent. per annum on the preference shares, to pay £874 interest upon funding certificates, to apply a like sum of £874, as arranged, to the redemption of funding certificates, and to pay a dividend at the rate of 10 per cent. per annum on the ordinary shares. A balance of £7,443 remains to be carried forward. At Queen's Ferry there has been an increased output, with better profits, from the steel works, and the result of the half-year's working would have been far from unsatisfactory (having in view the unfavourable conditions of working) were it not for certain failures in the motor-car trade, which have necessitated the reservation of a proportion of the Queen's Ferry earnings to meet bad debts either incurred or foreseen to be probable. The results obtained at Queen's Ferry, when considered with reference to the necessarily small scale of operations, and still more with reference to the limited and imperfect appliances at the disposal of the management, prove in the directors' opinion that the special products for which Queen's Ferry has now a high reputation (especially Vanadium steel) might form the basis of a sound and remunerative business in the hands of an organisation commanding adequate capital for the necessary extensions of plant. The Board greatly regrets that Sir Gilbert Clayton East, whose important services to the company are fully known to the shareholders, has definitely decided to retire. To fill this vacancy the Board recommends unanimously (except as regards Sir Gilbert, who expresses no opinion) the election of Mr. George F. L. Clayton East, at present the general manager at Queen's Ferry, where he has acquired experience which will be of value to the Board. It is not proposed to give Mr. Clayton East any additional remuneration as a director so long as he fills the office of general manager at Queen's Ferry and receives for his duties there his present salary of £800 per annum. But as the Board looks forward to finally disposing of Queen's Ferry, when the office of general manager will come to an end, it is proposed to arrange that so soon as Mr. Clayton East shall give up that office he shall be remunerated by a salary, as director, of £550 per annum. Owing to rearrangement of the work among the directors it is not considered necessary that there should in future be more than two giving their whole time to the executive work of the company. Under these circumstances Mr. Lazenby offers to retire at once if the company will pay him £600, being one-half the amount of the salary to become due to him under his agreement for the coming year. This proposal meets with the approval of the Board, who recommend its acceptance by the shareholders. The saving which would accrue from this reduction would be £600 for the coming twelve months and £1,200 per annum thereafter.

SOUTH LONDON ELECTRIC SUPPLY.—The report for the year ended December 31st, 1907, shows total receipts amounting to £33,992, and expenditure to £18,192, leaving, together with the amount brought forward, the sum of £19,605 available for distribution. After allowing for depreciation and interest on debentures and loan from bankers, there remains a sum of £15,479 to be carried to the general balance sheet. Out of this the Board recommend the payment of a dividend at the rate of 4 per cent. per annum on the original capital as it existed on December 31st last, carrying forward a balance of £2,479. At the end of 1907 there were connected to the company's mains the equivalent of 162,230 8-candle-power lamps, showing the satisfactory increase for the year of 17,608 8-candle-power-lamps. Applications were then also in hand for an ad-

Digitized by Google

ditional 5,000 lamps. Although there has been, as of course was inevitable, a large decrease in the gross receipts from supply of current through the expiration of the temporary contract with the London County Council for supply to their tramways, the revenue from supply to the Corporation's other consumers has increased by £4,000 as compared with 1906, and the output by 551,641 units, being an increase of 27 per cent. The units sold for industrial purposes increased by over 46 per cent. In view of the high rates prevailing in the money market until quite recently, the Board have considered it desirable to defer the issue of debentures referred to twelve months ago until the present year, and arrangements have been made with the company's bankers for a renewal of the temporary advance in the meantime. The directors have been successful in coming to a satisfactory settlement with the borough of Lambeth over the long-pending dust destructor litigation, and consequently the appeal to the House of Lords against the decision of the Court of Appeal was withdrawn. The special resolutions for reducing the share capital of the company from £325,000 to £260,000, which were unanimously confirmed by the shareholders on January 7th last, came before the Court on March 14th, when they were duly confirmed by Mr. Justice Neville, and the readjustments of the various capital accounts rendered necessary by such reduction will be at once carried into effect. The meeting will be held on the 7th inst.

SOUTH WALES ELECTRICAL POWER DISTRIBUTION.—The report for the year ended December 31st, 1907, states that, as intimated in the report submitted at the annual general meeting, held on July 27th, 1907, the late directors resigned their seats on the board, and the present directors were duly elected in their stead, and have since that date administered the affairs of the company. The working arrangement with the Treforest Electrical Consumers Co., Ltd., which was submitted to and approved by the shareholders at the last general meeting, has been put in operation, and the working of the Treforest Generating Station and the area supplied from that station was taken over by the Treforest Co. on September 1st, 1907. That company has already placed orders for about £26,000 for new and modern plant, which will materially reduce the cost of production. Negotiations are proceeding, and it is hoped will shortly be completed, for the formation of a similar consumers' company in the Cwmbran area, to take over and work the Cwmbran Generating Station. Agreements have been entered into with the Neath Rural District Council and the Bridgend Urban District Council for the sale of the Neath and Bridgend Generating Stations respectively. The directors are pleased to report that creditors in respect of the heavy liabilities appearing in the last balance-sheet have met the company in the most friendly manner by agreeing to accept preference shares in settlement of their claims, and liabilities for upwards of £78,000 have been settled in this way. A Bill is being promoted in the present Session of Parliament by this company jointly with the Treforest Electrical Consumers Co., Ltd., for the purpose, *inter alia*, of obtaining Parliamentary sanction to the matters referred to above. We report the proceedings on this Bill before the House of Lords in our "Parliamentary Intelligence."

TRACTION & POWER SECURITIES.—The report for the year 1907 shows a net revenue of £19,584, to which is to be added £3,242, brought forward from the previous account. The sum of £3,000 has been applied towards the depreciation of securities, and £15,000 has been transferred to the investments and reserve fund. The balance of £4,826 has been carried forward. Two of the company's securities—namely, the Mersey Railway 4 per cent. new first perpetual debenture stock and the Clyde Valley Electrical Power Co. ordinary £10 shares, for which there is no market quotation—have remained on the books at cost, and the directors stated that no revaluation of them will be made until their outcome is ascertained. Meanwhile, investments reserve fund stands at £65,000. During the past year the company's holding in the Mersey Railway debenture stock has increased by £19,297 in fulfilment of a contract previously entered into. The report points out that the earnings of the railway company in question continue to show a steady increase. Further calls have been paid up in respect of the company's holdings in the Clyde Valley Electric Power Co., the liability for unpaid calls being now reduced to £15,048. It has also been agreed to grant loans up to £100,000 to the Clyde Valley Electrical Power Co. for the purpose of extensions. Of this sum £29,684 was advanced last year.

WINDERMERE AND DISTRICT ELECTRICITY SUPPLY.—The report for the year ended December 31st, 1907, states that the gross revenue has shown a satisfactory increase, and the profit from installation work is somewhat larger than that of the previous year. The balance of the revenue account shows an improvement, which would have been much greater but for the increased expenditure on coal, mainly caused by the higher price. A first payment of 2 per cent. on account of arrears of interest has been received on the Keswick Electric Co.'s debentures, and the revenue account has benefited to the extent of £58 from this source, and the arrears of interest due from the Keswick Company have been reduced to the extent of £151. The sum of £245 has been spent on capital account, and, as foreshadowed in the last report, the increase in the company's business has necessitated the provision of additional machinery. The directors have therefore entered into a contract with the Brush Electrical Engineering Co., Ltd., for the supply and erection of a compound engine and alternator of the latest type, which should be at work before the end of June. The directors anticipate that this will effect economy in working expenses, and also believe that the provision of this additional machinery will largely diminish the risk of any interruption to the service. To obviate the necessity of supplying the Keswick Company with further capital, the directors have arranged that one of the machines now in use at Windermere will be moved to the Keswick works and lent to that company for a fixed annual payment. The balance of revenue account for the year is £2,061, to which is added £58 for interest on Keswick debentures, and £17 balance brought forward from last year, making a total of £2,116. Out of this has been paid debenture interest and bankers' charges, £774; interim dividend of 1 per cent. on preference shares, £250, leaving a balance of £1,092, out of which £500 has been transferred to depreciation reserve account, leaving for disposal a balance of £592. The directors recommend that a further dividend of 2 per cent. (making 3 per cent. for the year) be paid on the preference shares, which will absorb £500 and leave £92 to be carried forward to next account.

NEW COMPANIES

ELECTROLYTIC CO. (SPAIN AND PORTUGAL).—This company was registered on March 19th, with a capital of £255,000 in 250,000 ordinary shares of £1 each, and 100,000 founders' shares of 1s. each, to acquire interests in any invention relating to the production, treatment, application and use by electrolysis or otherwise of minerals and mineral substances, in particular to acquire the patents protecting the electrolytic process of L. M. Lafontaine in Spain and Portugal, to develop and turn to account the same, and to take over any mines, mining rights, and lands in Spain, Portugal, or elsewhere. The subscribers are J. Wilkins, F. Mitchner, H. Smith, F. S. Gee, J. Longworth, E. A. Chevalme, and S. Brillat. No initial public issue. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first, subject to the right of the Société Française Electrolytique to nominate two. Qualification, 100 ordinary or founders' shares. Remuneration as fixed by the company.

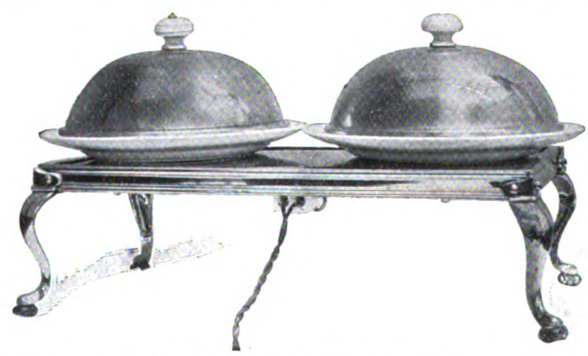
L. J. HEALING & CO., LTD.—This company was registered on March 7th, with a capital of £100,000 in £10 shares (5,000 preference and 5,000 deferred), to adopt an agreement with L. J. Healing and E. Eddison, and to carry on the business of importers of electrical and other machinery, electricians, mechanical and general engineers, workers of and dealers in electricity, suppliers of motive power, &c. The subscribers are: L. J. Healing, W. Kunsley, J.P., R. Tozer, R. Millbourn, H. E. Fisher, A. L. Roberts and A. H. Tozer. Minimum cash subscription 500 shares. The number of directors is not to be less than two nor more than nine; the subscribers are to appoint the first. Qualification, £250. Remuneration £500 per annum. Registered offices: 84 Fenchurch Street, E.C.

HELPTOPHONE CO., LTD.—This company was registered on March 10th, with a capital of £1,000 in £1 shares, to carry on the business of manufacturers of and dealers in all kinds of electrical and mechanical equipment and accessories used in connection with telephones and telephonic installations, &c., and to acquire from J. J. Chiswell the benefit of certain existing inventions relating to telephones. The subscribers are: J. T. Boyes, E. O. Gillard, L. N. Holding, W. J. Grinhan, F. Waite, C. F. Court, and A. Bischof. No initial public issue. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first. Remuneration, 5 per cent. each of the net profits per annum. R. E. Smith is the first secretary. Registered offices: 42 Old Broad Street, E.C.

HYDE-BEADLE POWER SYSTEM.—This company was registered on March 10th, with a capital of £500 in £1 shares (125 preference), to acquire from C. Hyde Beadle the benefit of a certain invention relating to the transmission of power, to adopt an agreement with the said vendor, to carry out experiments for testing, utilising, and improving transmission gear, and to carry on the business of mechanical and electrical engineers, manufacturers of marine automobiles, and aërial motive power appliances, &c. The subscribers are: C. Hyde-Beadle, Mrs. M. E. Beadle, Capt. M. H. P. Riall-Sankey, R. A. Smith, J. P. Thompson, A. Arkell-Hardwick, Mrs. A. K. Arkell-Hardwick. No initial public issue. The number of directors is not to be less than three nor more than five; the first are C. H. Beadle, Capt. M. H. F. Riall-Sankey, and R. A. Smith. Registered office: Palace Chambers, Westminster, S.W.

"IDEAL" PLANTS.—This company was registered on March 7th, with a capital of £2,000 in £1 shares, to acquire the business carried on by R. J. Nicholson at Macdonald's Lane, Corporation Street, Manchester, as "R. J. Nicholson & Co.," and to carry on the business of electricians, electrical

Digitized by Google



and mechanical engineers, manufacturers of and dealers in dynamos, motors, and apparatus used in connection with the generation, distribution, supply, and accumulation of electricity, &c. The subscribers are: J. H. R. Reich, C. R. W. Menzies, W. S. Smith, C. J. Nicholson, H. T. Smeeton, A. Tracey, and J. H. Carmichael. No initial public issue. Registered without articles of association. Registered offices: 3 Macdonald's Lane, Corporation Street, Manchester.

KARABON CO., LTD.—This company was registered on March 12th, with a capital of £10,000 in £1 shares (2,000 preference, 3,000 ordinary, and 5,000 deferred), to adopt two agreements with F. W. Grierson and T. Taylor, and to carry on the business of wholesale and retail import and export merchants, makers, turners or manufacturers and vendors of carriage fittings, electrical accessories, &c. The subscribers are:—T. E. Godbold, J. H. Thompson, F. J. Gigg, H. G. Skipp, C. P. Kitchen, A. E. Brown, and N. Malone. No initial public issue. The number of directors is not to be less than two nor more than five; the first are F. W. Grierson and T. Taylor. Qualification, £100 shares or stock. Remuneration (except managing director), one guinea each per board meeting attended. Registered offices: 3 Church Passage, Shaftesbury Avenue, W.

MACCLESFIELD ELECTRIC LIGHTING AND POWER CO.—This company was registered on March 11th, with a capital of £25,000 in £1 shares, to take over Provisional Orders and Electric Lighting Orders, to undertake the supply of electricity for light and other purposes in the United Kingdom, to carry on the business of electricians and engineers, &c. The subscribers are: A. V. Ward, W. P. Heermann, J. Clark, G. H. Park, S. Lloyd, W. T. Pullen, and C. Bucknall. Minimum cash subscription, 10 per cent. of the shares offered to the public. The number of directors is not to be less than three nor more than eight; the subscribers are to appoint the first. Qualification, £250. Remuneration as fixed by the company.

A NEW ELECTRIC HOT-PLATE

THE accompanying illustration represents a recent addition to the long series of heating devices useful for household purposes, which the British Thomson-Houston Co. have placed on the market. The device is a "hot-plate" for keeping plates and dishes warm, of sufficient size for accommodating two dishes. The actual dimensions are 18 in. long by 9 in. wide and 5½ in. high, and the material is copper with brass mountings. Speaking with some experience of household heating appliances, we do not think that anyone who has once kept their

breakfast hot electrically will ever return to methods which mingle a smell of methylated spirit with that of eggs and bacon. In addition to the complete form of electrical hot-plate illustrated, the company also supply electric heating elements for displacing the spirit lamp used on ordinary hot-plates, and any standard spirit-heated hot-plate, without water jacket, can be converted into an electric hot-plate by using one or more of these elements. To harmonise with the hot-plate for which they are intended, these heating elements can be obtained in either copper or silver plate. The devices are suitable for circuits of standard voltages.

CATALOGUES AND PAMPHLETS RECEIVED

CHOKING COILS FOR ARTIFICIAL INDUCTIVE LOAD.—Messrs. Morris & Lister, of Coventry, have issued a leaflet giving prices and particulars of the Morcom & Walshe design of special choking coils for use in conjunction with water resistances for testing alternators at any power factor. The apparatus in question was fully described in Messrs. Morcom & Morris's recent Paper before the Birmingham Local Section of the Institution of Electrical Engineers (see ELECTRICAL ENGINEERING, March 19th, p. 427), and is made in sizes ranging from ¼ to 1,050 k.v.a.

DRAWING OFFICE APPLIANCES.—A list from Messrs. Marriott & Stewart describes an apparatus for handling drawing paper in continuous rolls. In addition to the frame for supporting the reel of paper, there is an ingenious arrangement by which any length of paper can be easily cut off by means of a wire drawn through a narrow slot in an iron guide. The apparatus is made in vertical and horizontal forms for all the usual widths of paper.

ELECTRICITY IN PRINTING WORKS.—A well got-up pamphlet with this title has been issued by the Electrical Company, in which a number of excellent illustrations are given of electrically-driven printing machinery of a variety of types, and the advantages of electrical driving are pointed out. The various methods of control recommended for different sized machines are summarised, and a description is given of the methods adopted in the case of a large duplex rotary press.

FLAME ARC LAMPS.—The popularity of the "Excello" flame arc lamp has necessitated a third edition of the Union Electric Co.'s catalogue. The new form of the list sets forth various improvements relating to details of the lamp, improved arrangements of the carbons, and variations in the adjustments, which the extensive application of the "Excello" arc lamp for every class of exterior and interior illumination in various parts of the world has pointed out as desirable. A number of illustrations showing the lamps in use have been added.

PAPER SCALES AND TESTING APPARATUS.—A list is to hand dealing with scales of various forms for weighing samples of paper, micrometers, and a small testing machine for measuring tensile strength and elongation of paper. A set of tables of sizes and weights of different kinds of paper is given.

PORCELAIN INSULATORS.—A new list of insulators has been issued by the Sloan Electrical Co. A large number of types are dealt with, including the ordinary patterns, with iron bolt for supporting aërial lines from brackets and pole arms, shackle insulators, and insulators with swan-neck screws. Various patterns of bobbin and cleat insulators for surface wiring are also listed, together with rack insulators, leading-in tubes, and other accessories. A feature of the list is the series of designs of insulators made in two parts, whereby the conductor is mechanically clamped by the porcelain. Insulator brackets and other ironwork are included, as well as the Hoffman patent quick rivet jointer for connecting wires without soldering, and the "Clincher" wood plug, for fixing insulators in brick or stone.

RUBBER GOODS.—A catalogue from the Dunlop Rubber Company deals with general rubber goods required for engineering purposes, including hose-mats and matting, washers and packing, rubber gloves and belting.

TESTING SETS.—Messrs. Elliott Brothers have issued a new pamphlet describing their well-known "Century" portable-mains testing set, with details of the methods of using the apparatus for resistance, insulation, and capacity measurements and localisation of faults.

FORTHCOMING BOOKS

We are informed that an elaborate study of "Power Gas Producers," by Mr. P. W. Robson, chief engineer of the National Gas Engine Co., Ltd., is shortly to be published by Mr. Edward Arnold. It deals with the design and application of suction producers, non-bituminous fuel pressure producers, and bituminous fuel producers, and the author attempts to trace the connection between theoretical considerations and actual practice which should underlie all sound design. A feature of the book is to be the illustrations.

Messrs. Constable inform us that they have in view for immediate publication a work on the design, economical construction, and operation of central light and power stations. The purpose of this volume, "Steam Electric Power-Plant," by Frank Koester, is to give such information in regard to modern power plant practice as is essential to the engineer in designing steam-electric power plants. The book is the result of extensive experience in Europe and America, and will contain numerous excellent illustrations. Another new engineering work by the same publishers which will shortly appear is a concise pocket-book by Messrs. C. F. Marsh and W. Dunn, entitled a "Manual of Reinforced Concrete and Concrete Block Construction."

NEW PUBLICATIONS

"An Introduction to Electricity." By Bruno Kolbe. (London: Kegan Paul, Trench, Trübner & Co., Ltd.) 10s. 6d.

"First Stage Steam." Written to meet the requirements of the Board of Education Examination, and containing the examination papers set in the years 1901-1907. By J. W. Hayward. (Second edition.) (London: W. B. Clive.) 2s.

Fowler's Electrical Engineers' Pocket Book. Edited by William H. Fowler. (Manchester: Scientific Publishing Co.) 1s. 6d.

"British Engineers and Allied Professions in the Twentieth Century." Contemporary Biographies. Edited by W. T. Pike. (Brighton: W. T. Pike & Co.)

SUMMARY

A committee of the House of Lords has been appointed to consider the London Electric Power Bills after Easter. The chairman is Lord Cromer. (Page 542.)

A Paper by Mr. G. Stoney and Mr. A. H. Law was read at last Thursday's meeting of the Institution of Electrical Engineers, in which the development and present state of the designs of high-speed generators of Messrs. C. A. Parsons & Co. were described. Particulars and drawings of machines for both continuous and alternating currents were given in the Paper, including designs of historical interest as well as those illustrating the firm's latest practice. The most notable features of the continuous-current machines are the retention of the bipolar form up to large sizes, the preference shown for smooth as against slotted cores, the avoidance of carbon brushes, and the employment of compensating windings without commutating poles. All these points were severely criticised by the dynamo designers and others who spoke in the discussion. The alternators are more in accordance with prevailing practice elsewhere. The rotors are of the salient pole type, and a curious method of enclosing the field windings is adopted. The general opinion expressed in the discussion was that the slotted cylindrical form of rotor was preferable. The Paper concluded with a description of an ingenious arrangement for giving a certain amount of compounding effect to alternators. (Page 543.)

A short description is given of a new electrolytic method of making metallic mirrors for searchlights, which has been introduced recently. (Page 550.)

A long report on the arrangement of doors and seats in cars for underground electric railways in New York has been made by Mr. B. J. Arnold. The type recommended has double doors near the ends of the car. (Page 550.)

A map of Manchester, showing the position of the site of the forthcoming electrical exhibition is published in this issue. (Page 551.)

Some fine examples of manganese steel special work for tramway crossings and junctions have recently been put down in Newcastle. (Page 552.)

The tramway subway forming the connecting link between the northern and southern portions of the L.C.C. tramway system has been completed by the finishing of the construction of the extension from Aldwych to the Embankment, which will be opened to-morrow. Some views of the subway are given in this issue. (Page 553.)

Some statistics with regard to the electricity works in Germany are published. (Page 554.)

Digitized by Google

The electrical equipment of the R.M.S. *Mauretania* was described by Mr. W. C. Martin in a Paper read last Friday before the Institution of Engineers and Shipbuilders in Scotland. The total cost of the installation was £65,000. Current is obtained from four 400-kw. turbo-generators, and over 6,300 lamps are used. Electrical power is used throughout the ship, and motors aggregating over 2,000 h.p. are installed. A complete telephone and bell system is provided. Other applications of electricity include electric clocks and fire alarms, releasing gear for life-buoys, and electrical indicators showing the position of the water-tight doors, and calling attention by an audible signal to the partial extinction of the navigating lights. (Page 555.)

A lengthy Paper on electrolytic corrosion was read last week by Prof. W. W. H. Gee before the Manchester Local Section of the Institution of Electrical Engineers. The author dealt with the ordinary phenomena of electrolytic and ordinary corrosion, and methods of preventing such action, including the cases of lead-covered cables and electrolysis of water pipes due to stray tramway return currents. The phenomena of electrical endosmose were also discussed, especially in relation to the conductivity of concrete. Experiments on alternating electrolysis and electrolysis at high current densities were described. An interesting discussion followed. (Page 559.)

Under Electrochemistry and Electrometallurgy we describe a method for obtaining pure chloroplatinic acid by the electrolytic solution of platinum black. Platinum anodes are under no conditions absolutely unattacked when electrolysed in solutions of hydrochloric acid. But they appear to pass into solution quite readily when they are in the form of platinum black. G. Gin has been awarded the Frenzel prize by the Council of the American Electrochemical Society for his Paper upon the electrometallurgy of the rare metals. (Page 563.)

Under Electrical Science, in the British and American section, will be found notes on a series of experiments on the E.M.F.'s of concentration cells, and on a proposed magneto-mechanical method of detecting the momentum of the orbital motion of electrons in the material atom. An account is also given of the fifth of Prof. J. J. Thomson's series of lectures on "Electric Discharges through Gases," given at the Royal Institution on Saturday. The lecturer dealt first with the question of spark potentials for very small spark lengths, and then went on to consider the nature of the discharge in a partial vacuum under various conditions. In the Papers abstracted in the continental section, La Rosa points out some peculiarities in the spectrum of the singing arc, Drysdale evaluates the light per watt emitted by an ideal lamp, and De Broglie studies the gases obtained from a spark gap. (Page 563.)

In a patent specification by A. Steinacker and A. Plisnier published on Thursday last, and describing some improvements in wireless telephony, it is stated that good results have been obtained by substituting a mercury vapour lamp for the copper-carbon arc in the oscillating circuit. Among the other specifications published is one by R. D. Archibald relating to a petrol-electric system for motor vehicles. The transmission is by polyphase currents, and no brushes or sliding contacts are used. The transmission can be made purely mechanical at high speeds, but the prime mover is always running at a constant speed. Another specification by R. C. Browne relates to an improved microphone transmitter, and one by the British Thomson-Houston Co. describes an automatic starting device for polyphase motors. (Page 565.)

At the last meeting of the Acton Urban District Council the deficit on the electricity undertaking was alluded to. Current is taken in bulk from the Metropolitan Electric Supply Co., and the costs, including the cost of conversion in the Council's sub-station and 0·78d. per unit for distribution expenses, work out to 5d. per unit. The average price received is 4d. per unit, and the question of erecting a generating station is being considered. A consulting engineer is to report upon the undertaking.—A circular has been sent to wiring contractors in the Beckenham district reserving the right of the Council to increase slightly the price of electrical energy should the general adoption of metallic filament lamps render this necessary.—The poll of the ratepayers of Dunfermline as to the course to be adopted with regard to the Electric Lighting Order resulted in only 861 votes, being recorded upon a register of 5,600. 323 ratepayers voted for the erection of a generating station.—The Leeds tramways carried 73,734,085 passengers during the year ended March 31st last, and the receipts per car mile amounted to 10·49d., a decrease of 0·7d. compared with the figure for 1906-7.—The Fulham Borough Council has agreed to the use of overhead wires upon the Hammersmith-Putney L.C.C. tramways.—The Highways Committee of the London County Council recommend the issue of a guide to the tramway system, to be placed on sale at 2d. per copy.—An agreement has been come to between the Nottingham Corporation and the Nottinghamshire and Derbyshire Tramways Co. with regard to the construction and working of certain of the company's tramways by the Corporation. (Pages 567–569.)

The Accrington Corporation is applying for a loan of £7,500 for cables, and the Carlisle Corporation for £5,000 for a similar purpose. The Derby Tramways Committee recommend extensions of the tramways costing £5,500. The Frome Urban District Council propose to spend £10,000 upon its electricity undertaking. A 500-kw. direct-current turbo-generating set is required by the Rotherham Corporation, and the Wallasey Corporation requires a supply of automatic overload and reverse-current single-pole circuit-breakers. The Wimbledon Electric Lighting Committee has provisionally accepted the tender of Messrs. Babcock & Wilcox for two boilers at £4,710, and of the British Westinghouse Co. for high-tension switchboard and gallery at £2,606. (Page 569.)

At the meeting of the Electric Lighting & Traction Co. of Australia, Mr. J. B. Braithwaite said that it was hoped to make arrangements within the next few weeks, which would place the company upon a sound financial basis. The sixth annual meeting of the South Wales Electrical Power Distribution Co. was held at Cardiff last week, when Mr. W. Gascoyne Dalziel, who presided, gave a general review of the position of the company, and remarked that, but for the friendly assistance which had been given by the large party of creditors, in accepting a settlement of their claims in preference shares, nothing could have been done to save the company. The report of the Midland Electric Corporation for Power Distribution for the year 1907 shows a loss of £10,139. (Page 571.)

The House of Commons Committee presided over by Mr. Luke White, rejected the Dublin and Central Ireland Electric Power Bill last week. The Committee were obviously unconvinced with regard to the finances of the proposed scheme; and after the promoters' case had been closed, the chairman intimated to Mr. Freeman, K.C., that the Committee would require considerable assistance from him in this respect. Mr. Freeman replied that it was impossible to say what financial support would be given to the scheme until the form in which the Bill was passed was known. (Page 572.)

The Highways Committee of the London County

Digitized by Google

Council recommend the purchase of the Highgate Hill Cable Tramways, at an expenditure not exceeding £13,500. The price asked by the Tramways Company for their undertaking is £13,000. In a report by the Finance Committee on the matter, estimates are given for the reconstruction of the tramways upon either the conduit system or the overhead trolley system. (Page 574.)

Some recently introduced electrical appliances, including a time element cut-out, an electric kettle, and a new lamp-holder, are described on pages 575 and 576.

It is always interesting to hear descriptions of pioneering work in connection with an important branch of engineering, and it is often that a consideration of difficulties which have occurred and been surmounted in earlier days is of great assistance in solving the problems of the present. It was thus particularly fitting that the meeting last Thursday at the Institution of Electrical Engineers, which resolved itself into a debate upon details of design of present-day turbo generators should have been commenced with a historical sketch by the representatives of the firm of Messrs. C. A. Parsons & Co., for this firm was the pioneer of high-speed electrical machines as well as of the turbines by which they are driven. We have spoken of the Paper as historical, although it contains details of recently constructed machines; the designers who took part in the discussion were practically unanimous in the opinion that even the newer generators described in the Paper could hardly be regarded as representative of the tendencies that we may expect to see followed in the future. We do not for a moment suggest that the machines as at present designed by the authors of the Paper are in any way unsuitable for their work, and indeed they are probably in many respects far better than the work of firms of less experience in this direction; yet we cannot help inclining towards the opinion of the majority of speakers in the discussion that history will repeat itself, and that, in spite of the greater difficulties, slotted cores, carbon brushes, and multipolar designs will become as universal in the case of continuous-current machines for steam turbine drive as they have for dynamos of lower speed. The smooth core bipolar pattern, with metal brushes, has been the pioneer in both cases, and we do not blame Messrs. Parsons, after having laboriously conquered the difficulties attendant upon its construction for high speeds, for hesitating before they abandon their well-tried friend. Similar hesitation was shown by another well-known maker a few years ago in the case of lower speeds, but the change was inevitable. The relative advantages of compensating winding and separate commutating poles do not seem to be quite so clearly defined, although some designers are emphatic in their pronouncements in favour of a combination of the two. The case of the turbo-alternator is simpler, and, as Mr. Hobart pointed out, perhaps more hopeful, although on some points—especially as regards the construction of the rotor—there is still some divergence of opinion.

Professor Haldane Gee's Paper on "Electrolytic Corrosion" is an attempt to classify a rather wide range of phenomena, utilising results drawn from an extensive bibliography, and from his own experiments carefully directed to obscure points—some of which are, however, hardly cleared up by Prof. Gee's work. One useful fact which is brought out prominently is the large extent to which "passivity" affects electrolytic action. This seems to explain some cases of apparent immunity from the action of stray currents, and is not confined to metals of the iron group, as is generally supposed. The effect of different salts in the electrolyte formed by the moisture of the soil as favourable or otherwise to passivity seems to be more important than their chemical composition. The nature of the solid constituents of the soil is also an important element in modifying corrosion of buried metal exposed to stray currents. There is a good deal of reason to suppose that some soils act as depolarisers, and give rise to the apparent "metallic resistance" of earths noted by Claude. There is much else in the Paper throwing light upon corrosion, and suggesting further research. The discussion dealt mainly with electrolysis due to stray currents, but without disclosing any serious cases of damage in the United Kingdom. The South Staffordshire example alluded to by Mr. Watts was rather worse than he stated as to potential difference over the system, but it lasted for about twelve years with no claim for damage, and it may be stated on very good authority that the rails at the worst points showed no more corrosion than the rails on steam tramways of equal age in the same district. As they were anodes for all the stray current they ought to have suffered more severely than any pipe which could take but a fraction of the current. It is likely that concrete is as good a protection against electrolytic as against ordinary chemical corrosion. Mr. Cunliffe went into some speculations on the conditions of safety and danger which seem well founded. To his remarks on earth conductivity may be added that experiment shows that no decrease in resistance between earth plates twenty yards apart (as per the B.O.T. regulations) results from increasing the plate area beyond four feet square. Damage to cable sheaths seems more common than damage to pipes. The high combining weight of lead makes corrosion show sooner, but the root of the troubles is half-hearted earthing. Lead sheaths should be thoroughly and continuously earthed, or thoroughly and continuously insulated, and the latter is hardly practicable.

The rejection of the Dublin and Central Ireland Electric Power Bill last week by a Committee of the House of Commons draws attention to one aspect of private Bill legislation which may well create alarm in the minds of promoters. The plain inference to be drawn from the decision of the Committee which dealt with the Bill is that the financial position was considered too weak. One of the first points of attack made by an opponent to any scheme before a Parliamentary Committee is as to the sufficiency of the financial backing, but formerly this method of opposition did not have the same effect with a Private Bill Committee as it does now. In those days it was not a regular custom to insert a "cessor of powers" clause in Bills, so it was inevitable that some Acts of Parliament should be passed authorising works the erection of which was greatly delayed, or in some cases indefinitely postponed. So far as the electrical industry is concerned, a case in point was a

group of London tube railways, the original promoters of which were unable to proceed with their schemes until the advent of American capital in connection with the conversion of the Metropolitan District Railway from steam to electric traction; in the case of the North-West London Railway, a scheme which was not taken over by the London Underground Electric Railways Co., of London, nothing of a definite character has yet been accomplished, although the line was authorised by Parliament in 1899. Four or five years ago a new policy was initiated in Parliamentary Committee rooms, which, in effect, laid it down that no Bill should be passed unless the promoters gave some sort of guarantee at the outset that the capital would be subscribed. Obviously if this policy is pursued relentlessly, it must tend to discourage private Bill legislation to a very large extent. Promoters of any scheme should arm themselves with the very best evidence of a financial character that they can secure; but there is always the one difficulty to be surmounted, namely, that very few people can be induced to guarantee capital before they are aware in what form the Bill will leave the Committee rooms, for it is quite possible that clauses may be inserted by the Committee of one of the two Houses of Parliament which, from the point of view of the investing public, may make the scheme a hopeless one. If there were an unwritten law that a Committee must reject a Bill if a substantial portion of the capital is not guaranteed beforehand, however promising its engineering and commercial prospects, serious injustice might be done, but it rests with the Committee itself to exercise discretion in each case. In this connection attention may be drawn to the North-East London Railway Act of 1906, in which a provision was inserted that half the capital was to be subscribed within twelve months, failing which the powers under the Act would cease. Without passing any opinion on the technical merits of the Dublin and Central Ireland Power Bill, which embodied a novel scheme for the utilisation of Irish peat bogs for the production of power gas to be employed in an electric power scheme, we cannot but think that, in a case like this, in which no alternative or competing scheme was proposed, the Bill should not have been thrown out merely because no definite guarantees could be given as regards the capital available for putting the powers into effect after they had been granted.

LONDON ELECTRIC POWER BILLS

FOLLOWING on the rejection by the House of Commons of a recommendation by the House of Lords that the London Electric Power Bills should be sent to a Joint Committee of both Houses, comes the appointment of a Select Committee of the Upper House to deal with the Bills in question. The committee is as follows:—Lord Cromer (Chairman), Lord Welby, Lord Lytton, Lord Cobham, and Lord Lamington. Lord Welby was Chairman of the Finance Committee of the London County Council when, in 1905, it entered a strong protest against the Council embarking upon a scheme for electric supply. Lord Lytton was a member of the House of Lords Committee of 1905 which passed the Bill of the Administrative County of London and District Electric Power Co., subsequently blocked at the third reading stage in the House of Commons. Lord Cobham was a member of the Royal Commission on London Traffic.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, APRIL 9TH.

Institution of Electrical Engineers: Leeds Local Section.

7.15 p.m. Annual General Meeting at the University for the election of officers for the ensuing session. The following Paper will also be read:—"Heating of Enclosed and Ventilated Motors," by Wilson Hartnell.

Institution of Electrical Engineers.

8 p.m. Ordinary meeting at 25 Great George Street, Westminster. Paper to be read:—"Electric Supply Prospects and Charges as affected by Metallic Filament Lamps and Electric Heating," by H. W. Handcock and A. H. Dykes.

L.C.C. School of Photo-Engraving.

8 p.m. Lecture by Sherard Cowper-Coles, on "Some Notes on Electrotyping."

FRIDAY, APRIL 10TH.

Institution of Mechanical Engineers.

8 p.m. Meeting at Storey's Gate, St. James's Park, London. Papers to be read:—(1) "The Governing and Regularity of Gas Engines," by James Atkinson; (2) "The Effect of Mixture Strength and Scavenging upon Thermal Efficiency," by Prof. Bertram Hopkinson.

Physical Society.

8 p.m. Meeting at the Royal College of Science, South Kensington. Agenda:—(1) "An Experimental Investigation of the Nature of X-rays," by Prof. W. H. Bragg, F.R.S., and Mr. Madsen. (2) "Short Spark Phenomena," by W. Duddell, F.R.S.

Royal Institution.

9 p.m. Evening discourse on "The Carriers of Positive Electricity," by Prof. J. J. Thomson, F.R.S.

SATURDAY, APRIL 11TH.

Royal Institution.

3 p.m. Afternoon Lecture VI., on "Electric Discharge through Gases," by Prof. J. J. Thomson, F.R.S.

Birmingham and District Electric Club.

7 p.m. Meeting at the Colonnade Hotel, New Street. Paper to be read, "Electrical Train Lighting," by S. H. Bridcut.

Institution of Electrical Engineers, Students' Section.

Visit to the Electric Lighting Station of L.N. & W. Railway, at Chalk Farm.

TUESDAY, APRIL 14TH.

Institution of Electrical Engineers: Manchester Local Section.

7.30 p.m. Meeting at the University. Paper to be read:—"The Management of Engineering Workshops," by Eustace Thomas.

CORRESPONDENCE

THE FUTURE OF THE TELEPHONE SERVICE.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In a footnote to my letter of 16th inst., you state that I am mistaken as to Mr. Webb's relations with the National Telephone Company. The error, however, does not lie with me. The *Newcastle Chronicle* of March 10th states definitely that he is chief of that company's contract department, and this accords well with what has been generally known for a long time, although his official designation may be different. Under cross-examination at the last Brighton inquiry, where he had given evidence as an independent witness, he admitted that he was in the employ of the company. It is, therefore, too late in the day to pose otherwise than as a paid advocate. As such, and in that guise, he is, no doubt, entitled to a hearing and to have his views considered. But he comes forward as an unbiassed commentator, and I decline to discuss telephone matters with him on that basis, or to meet his statements about Glasgow or the other municipal telephone systems otherwise than by a direct denial of their truth. The municipal telephone authorities have long pressed for a Select Committee to enquire into their affairs. This Mr. Webb—*i.e.*, the National Telephone Company—and the Post Office are, above all things, anxious to avoid, because they know that the increased tariffs are artificial and incapable of justification. The position is that the Municipal Telephone Systems court inquiry, while their traducers shirk it. Let the telephone community adjust their views accordingly.

I am, Sir, &c.,

A. R. BENNETT.

Westminster,
March 31st, 1908.

HIGH-SPEED ELECTRICAL MACHINERY

A PAPER by Mr. Gerald G. Stoney and Mr. A. H. Law was read at last Thursday's meeting of the Institution of Electrical Engineers, in which the development and present state of the designs of high-speed generators of Messrs. C. A. Parsons & Co. were described.

Continuous-current Machines.

The first high-speed dynamo made for direct coupling to a steam turbine was designed and constructed in 1884 by the Hon. C. A. Parsons. The armature was 2⅝ in. in external diameter, and the core, built of very thin iron plate, was 2¼ in. diameter and 8 in. long. There were 50 conductors, and at 18,000 revs. per minute (the normal speed) the output was 75 amperes at 100 volts, or 10 E.H.P. The surface speed of the armature was about 206 ft. per second.

In this early armature the spindle was of high carbon steel to give the greatest possible strength, the diameter at the centre being 1¼ in., and the bearing ½ in. diameter by 3½ in. long. The core was smooth, 2¼ in. diameter, with notched driving discs of red fibre at each end, and on it was wound a drum-winding with barrel ends, the whole being held together by binding wire to withstand the centrifugal force. The commutator was made up of sections held by dovetailed rings with asbestos insulation.

These armatures gradually increased in size until in 1889 they reached the size of 60 kw. at 6,000 revs. per minute, the cores being 7 in. diameter and 18 in. long, the output being 600 amperes at 100 volts. These early types of dynamos were all bipolar with shunt-wound horseshoe magnets. The number of commutator segments were usually 12 for 50 or 65 volts, and 18 for from 80 to 100 volts, and in all but the smallest sizes there was only one complete armature-turn per segment. In these plants the sparking was not at that time considered excessive at full-load, though it would be considered so according to present practice, but even as early as 1885 it was recognised that it ought to be possible to avoid both sparking and shifting of the brushes by a compensating winding, and such a winding through holes in the cast-iron pole-faces (see Fig. 1) was tried, but the benefit was found to be very small, and it was not gone on with. It is now known that the reason of its want of success was that the ampere-turns of the compensating winding were only about three-quarters of those on the armature and that, had these ampere-turns been trebled, the great improvement effected by the adoption of compensating winding in 1903 would have been accomplished some eighteen years sooner.

In 1889, on account of the temporary loss of the 1884 patent for spiral drum end connections, an armature was constructed with a series of insulated discs at each end of the core, each connected to opposite conductors, an arrangement identical electrically with the ordinary drum-winding, but although it worked very well the cost and difficulty of manufacture were found to be excessive, and it was decided to adopt a gramme armature. Besides this, it was early seen that for a given voltage a certain number of commutator segments were necessary, and that the sparking to a large degree depended on the ampere-turns in the armature, and since the gramme armature had twice as many segments as the drum for the same number of conductors, it appeared that the result should be better. Several turbo-dynamos were made with armatures of this type. At this time also was introduced the construction of commutator with steel rings shrunk on over mica holding the segments in place against the centrifugal force, a construction which has been universally adopted by all makers of high-speed dynamos. Also, in some cases, fan blades were fitted to these commutator rings for the purpose of both cooling the armature and also the commutator.

The chief defects of these armatures were that sparking was not reduced, owing to the large self-induction of a gramme winding, and that the heating was excessive both on account of the difficulties of effective ventilation and also through the heating of the spindle due to its revolving in the stationary internal field of the armature.

For these and other reasons on the recovery of the patents in 1894 the drum armature was reverted to with considerable improvements in detail, ventilating ducts being provided along the cores to give internal cooling, and the conductors being much more efficiently laminated. And here it may be said that in all these high-speed armatures the cores are smooth, or nearly so, and the windings extensively subdivided to prevent eddy currents. Slotted cores for high-speed armatures have been used with some success, but on account of the much higher self-induction of the windings it is, in the authors' opinion, impossible to obtain as good results as with the smooth core type. Slotted core armatures have been built by Messrs. C. A. Parsons & Co. on several occasions, but results were never obtained which could in any way compare with those given by smooth, or nearly smooth, cores.

In some of the most recently built armatures of large size the conductors have been laid in slight grooves in the core. These grooves provide a means of preventing the conductors from moving, and the iron between the conductors reduces the reluctance of the air-gap to some extent. The conductors are held to the core by binding wire made of steel piano wire, which experiments have proved to be better adapted to the purpose than bronze wire.

In all these earlier dynamos the magnets were of the ordinary type, generally horseshoe; but even when the size was limited to 200 kw. at 3,000 revs per minute, although the commutation was good when the brushes were properly set for the load, heavy sparking was experienced on large variations of load, such as are met with in the case of traction plants.

The first method of meeting the difficulty was to automatically shift the brushes according to the load, this being effected (see Parsons and Stoney's patent 9203/00) by moving the brush rocker by a piston controlled by a spring and actuated by the steam pressure at the inlet to the turbine. The angular movement required by the brush rocker is approximately proportional to the load, and the pressure at the inlet to a turbine is also proportional to the load, so that it is easy to arrange for the brushes to be shifted the right amount. This arrangement, however, was not rapid enough to meet sudden and large changes of load, and under such circumstances some sparking occurred during the interval of lag.

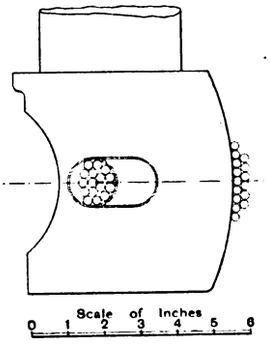

Fig. 1.—Compensating Winding, made 1885.

In 1903, after a series of experiments, Messrs. C. A. Parsons & Co. constructed a 300-kw. 2-pole compensated dynamo working at 3,000 revs. per minute at a voltage of 500, in which the ratio of compensating ampere-turns to armature ampere-turns were as high as 2·4. The armature dimensions (with the exception of the commutator, which was, of course, larger) were similar to the standard 200-kw. plant of that date, and at once remarkable results were obtained, since it could be loaded up to 800 kw., and when that, and even greater loads, were thrown on and off with a circuit breaker, there was no need to alter the position of the brushes nor any excessive sparking.

This compensating winding is chiefly concentrated on the pole-pieces, is made with from 2 to 2½ times the number of ampere-turns that are on the armature, and there is a very large excess sufficient both to neutralise the distorting effect of the armature windings on the field and at the same time to provide a commutating field for reversing, without sparking, the current in the coil undergoing commutation. Owing to the width of this field the brushes need not be so accurately set, and there is considerable range of sparkless commutation at all loads. Since this method of compensating has no iron commutating pole, it has the advantage that there is no self-induction to cause time lag at sudden changes of load; as the field in the gap between the poles is entirely in air it instantly responds to changes of current in the compensating winding, and thus the sparking often seen when there is a sudden change of load with commutating poles is avoided and the risk of a flash-over largely reduced. Also, since there is no iron to become saturated, the commutating field is always strictly proportional to the load, and thus the trouble due to saturation causing sparking at some loads and not at others is avoided.

The advantages of a compensating winding will easily be

Digitized by Google

seen to be much more than those due to fixed brushes and better commutation, since it has enabled not only the number of segments for any given voltage to be reduced, but also the ampere-turns on a given diameter of armature to be increased. This enables a larger output to be obtained for a given speed, or, what is the same thing a higher speed to be used for a given output. It may here be mentioned that no difficulty has been experienced in running these compensated dynamos in parallel with one another or with other types, although in all cases they are self-exciting, no separate exciter being used.

Fig. 2 shows a 1,000-kw. dynamo for 500 volts running at 1,200 revs. per minute, two of these being coupled to a 2,000-kw. turbine. These dynamos are for 500 to 600 volts, and carry an overload of 25 per cent. for two hours without sparking or undue heating. They are 4-pole, the armature core being 36 in. in diameter and 23 in. long, with 192 conductors. The commutators have 96 segments and are 18 in. in diameter with an effective length of 24 in.

Fig. 3 is a 750-kw. at 1,800 revs. per minute for 480 to 560 volts. It is a 2-pole, the core being 27 in. in diameter and 25½ in. long, the commutator having 42 segments, the diameter being 14 in. and the effective length 33 in., the number of conductors being 84. This machine has very good commutation, an overload of 33 per cent. or 1,000 kw. being able to be suddenly thrown on or off without any sparking whatever being visible at the brushes.

The authors have found brass-wire brushes running on a grooved commutator to give the best results. The grooving has the advantage of increasing the surface of contact, and of allowing the brush to better follow the irregularities of the commutator. The formation of commutator before referred to, and at present used by all manufacturers of high-speed continuous-current dynamos, was first designed in 1890 by Mr. Parsons, and has since been used with very few modifications. The bars are held in place against centrifugal force by massive steel rings shrunk on over mica bushes, and the commutator as a whole is supported on cones at each end. One of these cones is so arranged that it has a small amount of liberty to slide along the shaft longitudinally, and thus allow for the expansion and contraction of the copper. In building the commutator, the bars with mica insulating strips attached are first assembled and held in place by massive clamps, or by one or two layers of steel binding wire put on temporarily. The mica for one of the rings is then built up by slipping pieces of leaf mica under large rubber bands, and when a sufficient thickness has been obtained the mica is tied in place with string and the rubber bands removed. A steel ring is then slipped on at a red heat, stops being arranged to make it take up its proper position. As it goes on it burns away the string and grips the mica so tightly that the latter can readily be turned and trimmed back close to the ring, and presents a smooth black surface like a solid mica sleeve. In a commutator with only one section there are two of these steel rings, one at each end, but in long commutators several are required to counteract the centrifugal force tending to bend the commutator bars.

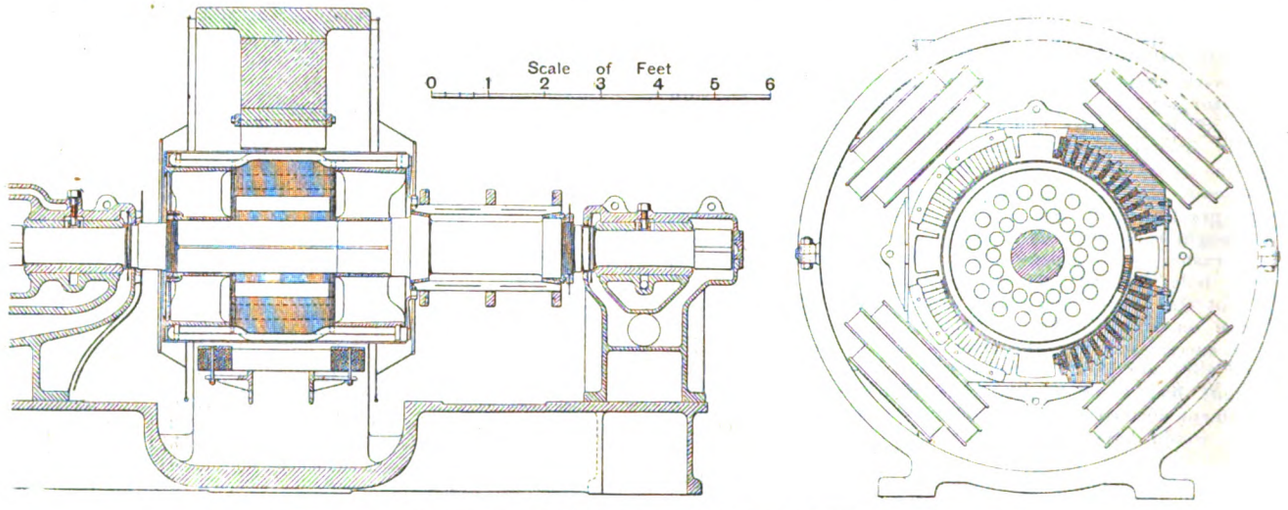

Fig. 2.—1,000-kw. Turbo-Generator, 500 volts, 1,200 revs. per min.

Alternators.

The first turbo-alternators made were for the Newcastle and District Electric Lighting Company, Ltd., four 75-kw. sets being installed in 1889 in their Forth Banks station. They generated single-phase current at 1,000 volts, and being 2-pole on a supply at 80 ~ ran at 4,800 revs. per minute. They were of the revolving armature type, and had a smooth core 7½ in. diameter by 30 in. long with a single shuttle winding held on by binding wire, the ends being brought to slip rings. External or surface ventilation was solely relied upon for the dissipation of heat. A considerable number of turbo-alternators of 150 kw. at 4,800 revolutions were made for the electric supply stations in Newcastle, Cambridge, Scarborough, and other places, having cores 8¼ in. diameter and 32 in. long. A square 4-in. spindle was employed with radial ducts and holes through the winding to pass air for cooling. In 1894 the first of a series of 350-kw. turbo-alternators were made for the Manchester Square Station of the Metropolitan Electric Supply Company. These supplied single-phase current at 1,000 volts, and had 4-pole revolving armatures running at 3,000 revs. per minute, giving 100 ~ Their cores were 17½ in. diameter by 57 in. long, and were provided with twelve 1¼ in. holes passing the whole length of the armature, air being drawn through by a fan though no radial cooling was provided. The first few were surface-wound, but owing chiefly to the eddy currents developed in the conductors, which were large and insufficiently laminated, there was considerable trouble from heating, and they were subsequently altered to a tunnel winding with sixty holes ¾ in. diameter, forty of which were filled each with one conductor, the remaining twenty holes being empty since the alternator was single-phase. Two- and three-phase alternators were also made on the same lines, the most noticeable of this type being the two 1,500-kw. 2-phase 2,000-volt plants, which were installed in 1904 at the Neepsend Station of the Sheffield Corporation. The crossing of the windings at the ends, however, makes the problem of a revolving polyphase armature much more difficult, especially at high voltages, though, on the other hand, the iron loss, especially in 2-pole plants, is only about one-third of what it is with a revolving field. The real trouble came when it was attempted to make a 1,500-kw. 40-periodicity 4-pole 3-phase alternator, with a revolving armature running at 1,200 revs. per minute, and a voltage of 6,000. It was found impossible to insulate the end winding sufficiently, and at the same time to get rid of the heat generated, and as a result the modern type of revolving field was adopted.

The design of the stationary or high-tension element follows low-speed practice fairly closely. It has, however, been found necessary to introduce a special system of brackets or clamping rings to hold the end windings against the enormous forces developed in case of a short or other serious disturbance on a system.

Fig. 4 shows a longitudinal and cross-section of one of the 4,000-kw. 3-phase alternators at 6,000 volts installed at Carville power station. The stators are split long the horizontal diameter and so arranged that the top half can be lifted by breaking only four electrical joints. This construction has the advantage for plants of large size that the rotor can be lifted out direct, but it rather complicates the end windings. The plant illustrated is capable of carrying 6,000 kw. for two hours, and on its official trial was loaded for half an hour up to 7,000 kw.

It is, however, in the rotors of high-speed alternators that the greatest diversities of design are to be found. A great deal has been said as to the relative merits of salient pole

Digitized by Google

as compared with cylindrical-type rotors, especially as regards the voltage regulation of the alternators, but it appears that a much more important question is whether one design shows marked advantages mechanically over the other. Any difference there may be in the two types as regards voltage regulation is certainly small, and can easily be compensated for at small expense by other features in the design.

Newcastle-upon-Tyne Electric Supply Company, Ltd.. has a ventilation scheme with separately driven fans which were installed to enable the alternators to carry heavier overloads, although in the first instance the machines were run for some years with natural ventilation, and were well inside the figures guaranteed for temperature rise.

Messrs. C. A. Parsons & Co. have constructed 2-, 4-, and

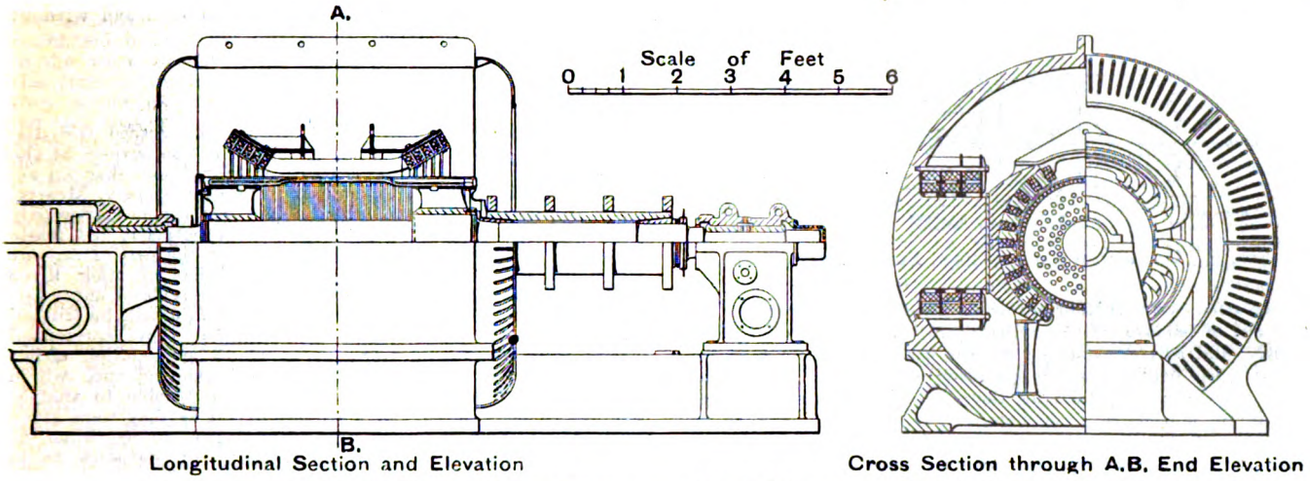

Fig. 3.—750-kw. Turbo-Generator, 480 to 560 volts, 1,800 revs. per min.

The question of ventilation is of very great importance in modern high-speed plant owing to the compact nature of the machines, which is a result of the limit placed on the diameter of the revolving portions by the high speeds of revolution, and in consequence it becomes necessary to make the maximum possible use of the space in the rotor which is at the designer's disposal.

The output of a given design may be regarded as directly proportional to the iron required to carry the flux, and nearly proportional to the copper to carry the required magnetising current, with the necessary insulation, so that if these can be increased at the expense of area to carry air ventilation and materials included for mechanical purposes only a valuable saving may result. This has been effected in many cases by providing artificial ventilation for cooling the iron and copper of the stationary element. The ventilation scheme which some makers have adopted is to provide a centrifugal fan at each end of the rotating element, or to make the rotor itself create the draught. Thus air is driven both round the end windings of the stator and also through the ducts in the iron core, and out through a chimney at the top of the stator casing. In other cases a separately driven fan is provided, forcing air

6-pole rotors of the salient-pole type. In the smaller 2-pole and 4-pole designs a solid construction with the coils wound in place is adopted. The 2-pole rotor is thus very similar in appearance to the old Siemens shuttle or H-type armature, with which many of us must have been familiar in the early days of electric lighting. The formation is excellent mechanically, since there are few loose parts, and the solidity of the construction enables great mechanical strength to be secured. The rotor body is bored at each end and shaft ends of special high tensile steel forced in, and then the whole turned up and accurately balanced. The balancing is done in three stages before winding the coils :—(1) By ensuring static balance on a pair of carefully levelled knife edges; (2) by careful measurement; (3) by running up to about one-third above normal speed in a specially constructed balancing machine. The combination of these three methods is essential, since while the balance may be perfect on the knife edges, this may be the result of one end of the rotor being heavy at one side while the other end is heavy on the other. In this case, though in perfect balance on the knife edges, there will be present when running a powerful couple travelling round at the same speed as the rotor and causing vibration. Careful measurement will generally

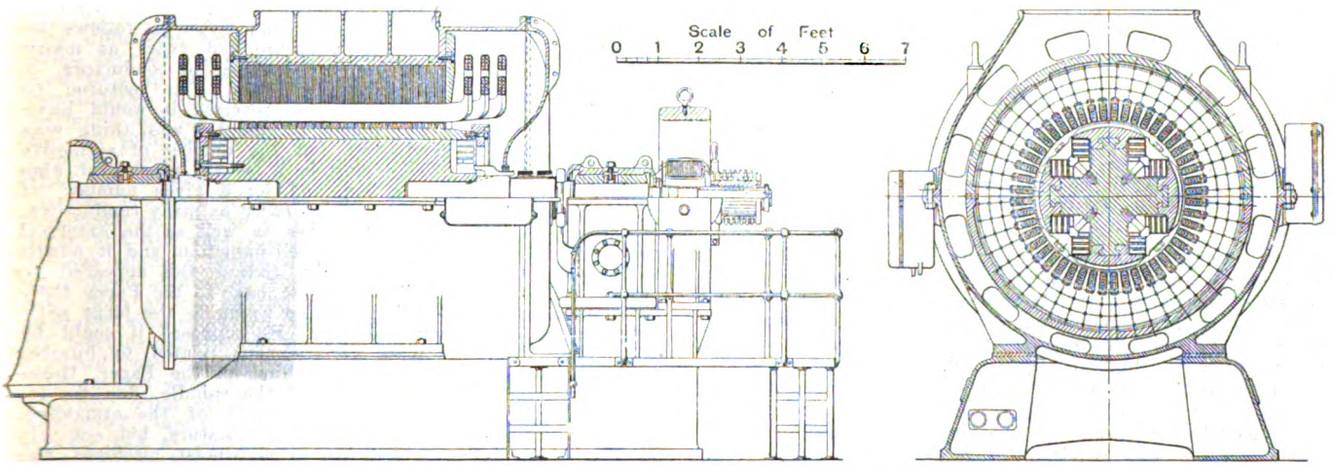

Fig. 4.—4,000-kw. 6,000-volt 3-phase Alternator with Exciter.

through both the stator and rotor of the alternator. In both these methods, or a combination of them, the exra pressure obtained results in the passing through the generators of large quantities of air, which is often arranged to be drawn from outside the building, so as to be as cold as possible, thus largely reducing the final temperature of the windings.

Among other stations, the Carville power station of the

show where weight should be removed or added to give both good static and dynamic balance, which is corrected and improved by actually running and fitting weights as required.

The rotor, after being thus balanced, is put into a horizontal winding machine, and the coils wound into coil cases, which are made of tinned steel and completely soldered up after the winding is completed. The ends of the coil are brought out

Digitized by Google

through a brass lip, soldered into the case, and fitting tightly round the connection to the next coil or to the slip rings, thus making a hermetically sealed coil.

A further advantage of coils thus wound and protected is the permanence of the balance of such rotors. Formerly with unprotected coils the windings had to find their own place as they were squeezed up by the centrifugal force, by the sliding of the insulation along metal surfaces more or less smooth. Thus the insulation was sometimes damaged and perhaps one

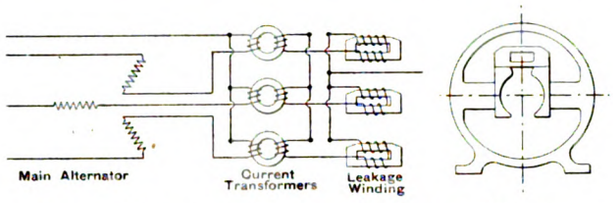

Fig. 5.—Diagram of Connections, Leakage Winding.

or two coils went further up than others, thus throwing the rotor out of balance. On running again other coils would move slightly, and so the balancing process had often to be repeated several times before a stable condition was reached. With the metal cases the coils take up their final position at once and stay there, and it is a common occurrence for a rotor to go straight up to 25 per cent. over speed the first time it is turned round without requiring any further balancing. In the case of large rotors the pole-tips are made to slide over a tee-shaped projection on the rotor body, and the coils are wound separately in coil cases and slipped over the poles before the pole-tips are put on.

As in the case of continuous-current machinery, one object is to get the maximum output at the highest speed possible. The strengths of the materials limit the diameter and length of the rotor and therefore both the available flux and ampere-turns This again limits in the stator the output for a certain inherent regulation. If, however, any method of compounding

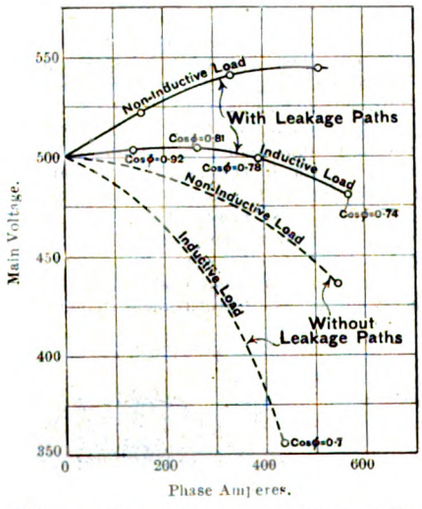

Fig. 6.—450-kw. Turbo-Alternator Voltage Regulation Putting on Load. Rheostats Unaltered.

the alternator to improve the regulation is adopted, much larger outputs can be obtained from a given carcase. Many methods of doing this have been proposed, but most of them depend on either commutating a portion of the alternating current or causing certain parts to become saturated as the load increases, or by varying the effective resistance of the winding on the exciter magnets. The first is objectionable on account of the trouble given by commutators, the second since the compounding will vary with varying voltage, and the third is generally too slow to allow for rapid changes of load. A method of compounding has recently been brought out (see Parsons' and Law's patents 24141/05 and 13712/07) which avoids these difficulties.

The exciter is provided with an alternative path for the magnetism in parallel with the armature which we call a "leakage path." This "leakage path" is provided with a winding, which is in series with the stator winding, and as the alternating current in this rises it chokes back the magnetism, or, in other words, increases the magnetic resistance of the leakage path. Thus more flux goes through the armature, and therefore the voltage of the exciter rises and compensates for the tendency of the main voltage to drop. In a 3-phase alternator there is generally one leakage path in each phase, and if the primary current is at high voltage, a current transformer is generally used. These leakage paths are easily adjusted for any desired amount of compounding; or for any power factor. Fig. 5 shows diagrammatically this arrangement fitted to the exciter of a turbo-alternator, and Fig. 6 gives the comparative regulation on varying load with and without the leakage path in action.

DISCUSSION.

Prof. Silvanus P. Thompson, F.R.S., who opened the discussion, said that in looking at the Paper it was obvious at the outset that it did not pretend to be anything more than an account of the highly successful doings of one firm, namely, Messrs. C. A. Parsons & Co., and as the object was confined avowedly to the manufactures of that firm and the progress it had made from the beginning, it would be invidious on the part of anyone discussing the Paper to drag in the products of other firms by way of instituting comparisons either favourable or unfavourable. If, therefore, he criticised the Paper in detail, he trusted that neither the authors nor the firm that they represented would think he did so from any want of appreciation either of the Paper or of the years of patience and advance which the Paper represented. He had taken the trouble to analyse the figures of a number of machines so far as they were given from the earliest types to the latest types, to see what he could get from these figures in the way of statistics as to the utilisation of materials. The result showed a very remarkable progress in the utilisation of copper and iron, giving a machine of larger and larger output in proportion to the quantity of material used, or, in other words, giving two machines which, in proportion to their output, were smaller and smaller. He had multiplied together the diameter and length of the armature core and divided that by the kilowatts of output, giving the "Steinmetz" coefficient. Beginning in 1884 with a small 8-kw. machine, the coefficient of size in proportion to output was 2·4 for a continuous-current machine. In 1889 the relative size had gone down to 2·1 for a 60-kw. machine, and in two recent examples of continuous-current machines of 750 kw. and 1,000 kw. respectively, this had further gone down to 0·917 and 0·8928; nearly almost exactly one-third, or three times as much output in proportion to the size of the armature as measured by the product of diameter and length. Turning to alternators, the result was even more striking. The earliest mentioned machine was 1889, namely, a 75-kw. single-phase machine, and the ratio was 3. A little later, with a machine of 150 kw., the ratio had gone down to 1·76. In 1894, with a 350 kw., the ratio was 2·8, but in 1894 to 1896 for a 1,000-k.v.a. machine the ratio had gone down to 1·73, and with the most modern machine described in the Paper, which was a 4,000-kw. 3-phase machine made for the Carville power station, this figure had gone down to 0·64. Thus the ratio had gone down from 3 to 0·64, a little more than one-fifth, or five times as much output in proportion to the size measured as a product of diameter and length. The firm that could do this in the years between 1889 and 1903 had certainly made a very remarkable advance. Early in the Paper there was a comparison between the winding of the Gramme armature and the drum type as follows:—"... and since the Gramme armature had twice as many segments as the drum for the same number of conductors, it appeared that the result should be better." He ventured to think that if the argument had been reversed it would have been argued the other way round, because the vital thing was not the number of conductors, but the number of segments for the commutator. There must be a certain number or else the commutation would be bad, and for a given number of segments the Gramme armature had twice as many conductors, because it had all the internal ones as well as the external ones, and that would increase the self-induction, and it ought to be worse and not better, and so, indeed, this appeared to be recognised by the authors, because later in the Paper they stated that sparking was not reduced owing to the large self-induction of the Gramme winding. He supposed it could be taken that this little piece of argument related to bipolar machines, because, in the next few lines of the Paper, there was a reference to the heating of the spindle, due to its revolving in the stationary internal field of the armature. That would be true for a bipolar ring armature, but scarcely so for a four-pole machine, as in multipolar machines the internal field through the shaft was negligible. The authors made an extremely interesting statement about the use of smooth core armatures in continuous-current machines, which appeared to be still preferred in these high-speed machines to slotted armatures, and the reason given was that better commutation could be obtained. But was this the only reason? It seemed to him that there must be another reason, namely, that with these very high surface speeds, if slotted armatures were used with slots of usual size, the frequency of change of the magnetism where the teeth go in and out of the polar edges would be deleterious, and that there would be set up in the

Digitized by Google

pole pieces eddy currents of a rather severe kind, resulting in a severe iron loss as a result of having a very high frequency of change. Surely that was one reason why teeth should be avoided in machines of this type. The authors stated that since the method of compensating used by Messrs. Parsons had no iron commutating pole, it had the advantage that there was no self-induction to cause time lag at sudden changes of load. He thought this statement was somewhat difficult to understand, because it seemed to him that if there were sudden changes of load, this would equally affect the current through the armature and the current round the series winding; it could not increase or decrease at a greater rate in one than in the other, and either or both might have self-induction, and the increase or decrease as a whole might be retarded, but they would both be affected equally, and, therefore, he could not see that the self-induction had anything to do with the want of compensation between the two. Another interesting detail was the arrangement of the commutator segments, first designed by Mr. Parsons in 1890, in which longitudinal expansion took place, which allowed for the expansion and contraction of the copper, the commutator as a whole being supported on cones at each end. He supposed that there was some kind of spring arrangement to take up the expansion—(Mr. Stoney: Yes)—otherwise the end of the ring would be liable to part company on contraction. In the Paper there was a brief discussion of the relative advantages of having the poles of the field magnet wound solidly as a whole, or having, on the other hand, the winding distributed in several slots. The authors stated that any difference there might be in the two types as regards voltage regulation was certainly small. Was that all that was wanted to be known? In those cases where the winding was divided over several slots, the middle region of the pole had more ampere turns round it than outlying parts, and the result would be that even if the air-gap was practically of a uniform width over the pole face, the flux would be concentrated more at the middle of the pole than towards the edge, because it was desired to have a distribution nearly approaching, in space, a sine function. That could be obtained in other ways, such as by the shape of the pole and overhanging tips; but was it not true that if the pole phase were entirely solid, they were more liable to have distortion of the magnetism laterally when there was an inductive load by the cross magnetisation? Thus, if the winding were concentrated in the way suggested by the authors, and making deliberately a stronger piece of pole in the middle, if the initial distribution of magnetism at no load was approximately a sine function without any cross magnetisation, that would be sheared over, and the E.M.F. curve would no longer be a true sine curve, and the heating would no longer be a minimum in the armature iron. There might be some advantage in that form of pole, because there would be less liability to such distortion and therefore less heating at full load. This might not be important; but he mentioned it to ask whether it had been found from the heat point of view that the iron loss at full load was really different between these two types. For the method of compounding through the excitor of the alternator mentioned in the Paper, he had nothing but the utmost admiration.

Mr. E. J. Fox (Messrs. Willans and Robinson) said that those who had been engaged in working up the turbine side of the business know well enough the difficulties to be faced quite apart from the electrical side. Mr. Parsons and his associates had had to work at the two together, and he was quite sure the difficulties would have disheartened most other people. Some four or five years ago, when Messrs. Willans & Robinson first took up the manufacturing of steam turbines, they found considerable difficulty in getting generators for coupling to turbines, and the few remarks in criticism of the Paper which he was going to make were based on experience with different types of generator made by different makers. He was sorry that the authors had confined their Paper as regards direct-current machines to those with smooth cores and corrugated commutators. He knew that machines of this type had, in the past, and still were, doing very excellent work, but he thought it was setting a comparatively low limit if they were to put this down as finality, which was practically what it amounted to. Both as far as the smooth core armature and the commutator were concerned, he was perfectly certain that the type of machine described in the Paper had got to give way to the toothed core machine and carbon brushes if direct-current turbine sets were going to seriously compete with reciprocating engines. First of all, as far as the smooth-core machine was concerned, surely nobody could call it mechanical. The conductor had to be laminated in order to avoid eddy currents, and had to be driven in the same way as the smooth-core machines were driven ten or fifteen years ago, by means of driving pegs. Then the conductors on the outside of the surface had to be bound down with steel binding wire, and it seemed to him that they were very liable to shift. Mr. Fox then referred to the success of the slotted core machines of Messrs. Brown, Boveri & Co. The authors stated that the objection was that they did not get such good commutation; but he did not think this was the case. With some dynamos with slotted cores, which Messrs. Willans & Robinson had put down, and others which he had seen on the Continent, the commutation was as good as was wanted. In principle these machines seemed to differ from the authors' designs in that, in addition to compensating winding there was a commutating pole, but it would seem as if this latter was the natural consequence of events. The commutating pole would certainly save a good deal of copper on the compensating winding, in so far as the air-gap was considerably reduced, and in addition to that it gave the commutating field just where it was wanted, instead of an indefinite field not concentrated so closely as it was possible to concentrate it with a commutating pole. Dealing with the commutator, he thought that the corrugated commutator with wire brushes was bound to die a natural death very soon. The only reason that he could see why wire brushes were used was that if the commutator got out of balance it did not matter to the same extent as with carbon brushes. He had been looking at some drawings of a new type of commutator which Messrs. Brown, Boveri were experimenting with at the present time, designed for working entirely with carbon brushes. The idea was to support the commutator in such a way that as the bars heated up expansion took place end-ways, and prevented bulging on the periphery. With regard to alternators, the authors had touched on the question of the salient pole *versus* the cylindrical type. He was entirely in agreement with them here. Messrs. Parsons had adopted the salient pole type of machine, and he thought from his experience that there was, at all events, very little to choose between the two. The salient type had perhaps these two advantages: (1) that better regulations could be obtained; and (2) bigger overloads could be maintained, due to the greater amount of copper. One final remark on the subject of alternators, dealt with the author's advocacy of compound alternators. There had been a good many of these brought out from time to time and discarded, and he thought the best machine was an ordinary alternator without any of the complications of compounding, and if closer regulation or voltage regulation were required, the use of a Tirrill regulator would enable them to do the thing as simply and cheaply as possible.

Mr. W. PARKER (Messrs. Siemens Brothers' Dynamo Works, Ltd.) said that the authors had dealt with the history of the direct-current turbo; he would like to add a few remarks upon the history and development of the direct-current machine in general. The authors had advocated metal brushes and smooth armature cores. Looking back to the early stages of the electrical industry, and more particularly to that period when the bipolar machine was at the height of its popularity, it was found that metal brushes and smooth cores were used exclusively, and in spite of the fact that these machines had to run on lighting circuits with very steady loads and at low speeds, it was found that these brushes required a fair amount of attention in order to get them to run sparklessly. With the advent of traction and fluctuating loads and large overloads, the fixed position of metal brushes was found to be entirely unsuitable. Carbon tips were tried, and while they effected some improvement they were found to be insufficient. Something new was required, and this was found in the exclusive use of the carbon brush. In this way carbon brushes were established, and smooth cores were abandoned, as the introduction of carbon brushes rendered possible the use of slotted armatures. He was therefore very much surprised to find that the authors still advocated that antiquated construction, the smooth-core armature and metal brushes, and a type of machine in which the commutation difficulties were exceedingly severe, and in which it was extremely desirable to get an armature wound in such a way that the winding could not shift, otherwise the machine would rapidly get out of balance. Moreover, he was convinced that in the very near future users would insist on carbon brushes and slotted armatures. When his firm first took in hand seriously the designing of direct-current turbos suitable for operating with carbon brushes, they soon found difficulties. The real difficulty was not vibration, as had been anticipated, but excessive heat from the commutator. Vibration could be got over by a suitable brush holder, but excessive heating did not lend itself to any very easy solution. They found it absolutely necessary, if carbon brushes were to be used on high-speed commutators, that artificial cooling should be employed. The particular form used by his firm was to have holes arranged axially in the segments of the commutator, with a fan attached to the shaft for introducing a powerful draught of air through these channels. There were other methods of cooling a commutator, such as diverting a stream of air on the surface of the commutator by means of a motor-driven fan, situated in the basement along with the other auxiliary machinery. He had found that the method of artificial cooling by means of axial holes, that the temperature of the rest of the commutator with carbon brushes, could be kept down to less than 40° F., and with a density under brushes of 45 amperes per square inch, the brushes used being those of Le Carbone manufacture, X and Z qualities. In connection with this question, he mentioned that one of the largest firms on the Continent, who had built upwards of one hundred direct-current turbos, had given up metal brushes entirely, and had gone over to carbon brushes, and they had always used slotted armatures. On the question of commutating poles and compensating windings, he said he

Digitized by Google

noticed the authors advocated the latter only. According to the Paper, their reasons were that when commutating poles were employed (1) there was sparking with sudden variations of load; (2) a tendency to flash over on the commutator; (3) that machines so fitted sparked at some loads and not at others; (4) that the sparking was bad at varying voltages. These statements were certainly incorrect. He had himself seen several machines fitted with commutation poles giving absolutely sparkless running under all these conditions, with the circuit-breaker tripped, and the full load current on the machine. With regard to sparking at varying voltages, he had seen machines fitted with commutation poles running absolutely sparklessly when the voltage had been varied from zero up to the maximum normal value. His firm, when testing these machines for commutation, in order to make the final adjustment in the test house before the machine left the works, always tested on short circuit. The brushes were short-circuited, and the machine gave its full current at 10 to 12 volts. On the question of machines with commutating poles tending to flash over, his opinion was that the flashing over problem was independent of whether there were commutating poles or not. He had seen machines run sparklessly and then flash over, the reason being that the volts between the adjacent segments were too high. This brought him to the disadvantage which the use of compensating windings alone possessed. According to the Paper, it appeared that the practice of Messrs. Parsons was to employ about 2 to 2·2 times the ampere turns on the compensating winding to that of the armature. It appeared quite clear that with such an excessive amount of compensating winding on the pole shoes, not only would they get the commutation flux reversing, but there would also be a very large distortion in the main pole, because if the compensating ampere turns per inch of circumference in the pole shoe were less than the ampere turns per inch of periphery on the armature, then clearly the distortion was not entirely neutralised. If, on the other hand, the ampere turns per inch on the pole piece were greater than the ampere turns per inch on the periphery of the armature, then they got flux distortion in the other direction, and he thought that with the large number of ampere turns utilised by Messrs. Parsons, the distortion would be actually greater than if no compensating winding was used at all. He thought there was very little doubt that the best construction for large units for direct-current turbos was a combination of commutating poles and compensating windings, as these were becoming now practically universal not only in England but also on the Continent.

Dr. R. Pohl (Phœnix Dynamo Manufacturing Co.) said that the main and critical features of Parsons' latest machines agreed very well with those factors which he had the honour of putting before the Institution a few months ago, the only difference being that the voltage per segment was about 50, as against 40 which he recommended. The main features of Parsons' direct-current machines were the compensating winding, the bipolar construction up to very large construction; the smooth core and the metal brush and corrugated commutator construction. Three of these points had already been dealt with by previous speakers, and he was quite in agreement with the opinions expressed as being in accordance with best modern practice. He was of the opinion that the smooth-core armature would have to give way in a very short time, and also the metal brush and the corrugated commutator. As regards over-compensating windings, he agreed with the previous speaker, who said that the field distortion was by no means eliminated. As a matter of fact, if they worked out the design of the 750-kw. generator, and calculated the field distortion, it would be found that the negative field distortion was about twice as much as it would be if there were no compensating winding at all. He did not mean to suggest that in Parsons' machines there was any great field distortion. It was kept down quantitatively by employing smooth core and a very big air-gap, and he believed the reason Mr. Storey advocated smooth core was that he employed his over-compensating winding. If he would concentrate the over-compensating winding in the neutral zone only, leaving so much ampere turns on the field as to prevent field distortion, he would find that the slotted core with the very much smaller air-gap would give better results. The second portion of the Paper, dealing with alternate-current machines, was very interesting reading, and contained one or two points which were distinctly novel. The first was the winding of the coils in hermetical sealed coil cases. He would like very much to have a more detailed description of how this winding was carried out. He did not see how the slipping of the coils in the cases was prevented, and he did not understand how the coil cases were secured. Another point of particular interest in the alternating-current dynamo was the leakage path method of compounding described in the Paper. The idea was very ingenious, and he congratulated Mr. Law; but at the same time he had some doubt as to whether it would work out in practice as a commercial success. The curves in the Paper showed that in order to maintain approximately constant voltage, an increased pressure of about 60 per cent. was necessary with a negative load of 0·8 power factor. That would mean that the total flux must be increased in the ratio of 1 to 1·6, or an enormous flux must pass through the leakage path. There was another consideration. As soon as that leakage path was completely saturated, say, 24,000 C.G.S. units, even then the permeability of the material was somewhere between 30 and 40. Assuming that the leakage between the pole tips, without any such leakage path, was 5 per cent., then the leakage which was left, even at the highest density, would be between 150 and 200 per cent. In other words, it seemed to him that the exciter fitted with such a leakage path would be about three times as large as an ordinary exciter. He did not know whether he had made a mistake, but it seemed to him that that was about the case. There was, further, the additional expense of the choking coil and of the current transformer, and he had some doubt as to whether that expense would be compensated for by the saving in the construction of the alternator.

Mr. F. H. Clough (British Thomson-Houston Co.) criticised the opinion expressed by the authors that the salient pole was preferable, more particularly for high speeds, which it was now the tendency to use. The salient pole machine could be regarded as, say, a four-pole machine, having four large slots, and necessarily, to get the same excitation, the conductors in each slot, and consequently the size of the slots, must be very much increased, *i.e.*, there were large size conductors and considerable difficulty in getting rid of the heat. Another feature, of course, was that in the overhanging portion of the slots, viz., the pole tips, there might be very heavy bending stresses, and the limit in the peripheral speed of the machine generally ceased there. Dr. Thompson had spoken of the distribution of flux round the periphery. With a definite pole machine this could be made practically anything that might be desired. With a cylindrical rotor, if advantage were to be taken of most of the periphery, then there was only a small portion in the centre of each pole which was not wound; consequently, there was a very increased density in this portion. With a well-distributed stator winding the effects of the higher harmonics could be very nearly eliminated by the coils in different slots being connected in series. The winding was then so distributed that the higher harmonics were eliminated, and consequently there was at disposal the use of any distribution of flux that they might care to use, and therefore, in order to keep down the density in the centre, it was desirable to make this a flat tip, *i.e.*, an even distribution of density across the pole tips. His company had made some machines with a modified cylindrical type of rotor. In these, the diameter over the poles was rather larger than between the poles, and the conductors were carried in slots. Consequently, they had the advantage of the exciting winding distributed in comparatively small slots, no bending stresses, and also, by the use of the increased diameter, the flux distribution could be spread over a considerably larger portion than if a purely cylindrical rotor had been adopted. The reluctance of this machine was variable, and was bigger between the poles than over the pole faces. Another advantage was that this increased diameter allowed a double depth of ring for retaining the winding. Some machines were running at 300 feet per second, and this ring, being sufficiently thick, required no internal support. The rotor was therefore made with a large hole in the middle, and adequate ventilation without any auxiliary fans was obtained.

Mr. Miles Walker (British Westinghouse Electric & Manufacturing Co.) said the question of salient poles *v.* cylindrical windings was a very important matter for the designer, and time would show which machine would survive. In his own opinion the cylindrical machine was the type which would survive, for the reason that from such machines it was possible to get the largest output from a given amount of material. The first striking difference in the two types was that in the cylindrical type there was a very short pole with a winding distributed over a great width, whilst with the salient type there was a comparatively long and narrow pole, from which there was a leakage across, whereas in the former there was very little leakage indeed. In the case of the cylindrical type the winding was supported mechanically in small sections, allowing the use of very much higher peripheral speeds. In the other type, the winding was more or less huddled together, and therefore the cooling of the copper was very much worse. In the Paper the authors had stated that the output of the machine was proportional to the sectional area of the pole into the sectional area of the copper, but he wished to point out that there were two other factors of very great importance which must also be considered. One was the current density at which it was possible to work in the copper, and the other the flux density at which it was possible to work in the steel. With the cylindrical type of winding it was possible to work the copper at least 50 per cent. higher than in the other case. Considering the saturation curves of the two machines, he pointed out that in the case of the salient pole type the limit of working must be fixed lower down on the saturation curve than if the cylindrical core were adopted. The reason was that as the flux increased the leakage increased, and a point was reached where the ampere turns in the pole were increased, and consequently the leakage, to such an extent as even to make the characteristic curve bend downwards, without increasing the flux at all. In the other case, a point was ultimately reached when the iron was saturated over a larger area than was the case originally, so that the curve was

Digitized by Google

always rising, and they could work at a higher point and still keep up the voltage on heavy loads. Why was it, he asked, that the cylindrical type had not been more used by many designers who really were very competent to judge of these things? One of the main reasons, he thought, lay in the construction of the end connections. It was easy enough to have a cylinder with a number of slots in it; and it was easy enough to hold the winding inside the slots, but difficulties arose in the portions which protruded at the ends. This was the trouble which had stopped the cylindrical type from being used, but he believed that if this difficulty were got over, and the end connections supported, then the cylindrical type was bound to supersede the other. The difficulty was that there was only a limited space, and bands or a ring were required to hold the wire down. In a type of construction which he had seen a good deal employed recently, and which had been successful in a very great number of cases, the copper bar was cut down to about half its width where it left the slot, and end connectors were then built up with copper straps, which went from one bar to the other. These were grooved with V grooves at the side, assembled and covered with mica, and held by means of end rings after the manner of a commutator. A steel ring, insulated with mica, is placed over the whole, where the bars are cut away. This form of construction enabled the use of enormous peripheral speeds without danger. He could give figures of the enormous outputs to be obtained from very small sizes. It was possible with a rotor of about 20 in. diameter to get 60,000 ampere turns. If they tried to put this in connection with a salient pole, and yet preserve a fair amount of the iron—because they must consider how much iron they would have—they would not be able to get within 50 per rent. of that figure, because they had to work at a lower current density, and there must be some kind of mechanical support, which always took up a lot of room, whereas with the other winding they mixed up the iron and copper electrically and mechanically. This enabled the building of a 2,000-kw. machine with a rotor of 20 in. diameter, and the active iron only 20 in. long; *i.e.*, a 2,000-kw. rotor about the size of an old-fashioned garden roller. This was the reason why the distributed winding looked promising in the future. Another reason was that it made the construction of the compounded alternator, which he described some years ago, more simple indeed. These alternators were used in a great number of places, in sizes varying from 500 kw. to 3,000 kw. capacity. They would hold their voltage on the ordinary power factors met with in practice from no load to full load. These compounded alternators had two features which were not to be found in an ordinary compounded alternator. Any arrangement in which the exciter was made to increase its voltage at the time when the load came on always had the drawback that there was a second or two seconds' lag, due to the self-induction of the field; so that if the load was jerked on, there was flickering in the lamps before the compounding could work; but with the arrangement mentioned above, the armature reaction was made to strengthen the field, and incidentally as the load came on the volts corrected themselves. It was possible to throw the whole load on from no load to full load with a switch, and with a lamp in parallel with the load there was not the slightest flicker or increase in brightness when the load came on.

Mr. H. M. Hobart thought they were very far from finality in this question. There were reasons for this, he thought. It was possible to overcome reactance voltage and armature reaction with compensating windings and interpoles, and both were fairly satisfactory, but they did not, of course, affect the peripheral speed, which was one of the chief troubles. The trouble of finding a brush to work smoothly with peripheral speeds of 30 to 40 metres per second was a mechanical trouble. It seemed to him that the reason why no very great success had yet been obtained with turbo-dynamos was that they were going contrary to fundamental laws, whereas in connection with alternators they were working in accordance with them. All designers knew that the properties of the alternating-current machine came out better the higher the speed, although he felt that this was being rather overdone; in fact, he thought the speed might be dropped a little, even if there was not so much economy. But the reverse was the case with continuous-current dynamos. The slower the speed the better would the direct-current dynamo come out, and they ought to be satisfied with a continuous-current dynamo running at slow, or, at any rate, medium speeds. There was another reason. The turbine did not show up favourably in comparison with reciprocating engines for steam consumption below 1,000 kw.; they did not want them to, and the thing worked out nicely in this respect. It was only in the larger sizes of turbines and alternators that the great economy over piston engines was shown.

Mr. A. H. Law, replying briefly to the discussion, dealt with a few of the points raised, and reserved a full reply for the journal. Dealing with Prof. Thompson's constants for different sizes of machines, he said that it must be borne in mind that these old machines were a good deal smaller than the later ones, and if they were to build a 20-kw. plant now at 18,000 revolutions, he did not think they could do any better than Mr. Parsons had done in 1885 as regards smallness for a given output. Mr. Stoney had himself gone into the design of the 1885 machines, and it was wonderful how near Mr. Parsons had been to good modern practice of to-day. A good deal had been said about the relative advantages of smooth core and slotted armatures. The fact was that Messrs. Parsons were simply relying on experience of both types. As was stated in the Paper, slotted cores had been built, and they would be the last to say that no good result had been obtained with them. Mr. Stoney and himself had both seen them running, but at the same time such exceptionally good results had been obtained recently with large two-pole smooth core machines with distributed compensating winding, that having that experience they were extremely loth for the moment to alter their design and go in for slotted cores and carbon brushes. The question of carbon brushes had been raised by nearly every speaker, and he was pleased that it had been raised, because anybody who said that carbon brushes were not going to be used in the future would be taking a very bold step. Neither Mr. Stoney nor himself had made any such statement. There was the possibility, or even a probability, that some form of carbon brush would eventually be used, and all commutators constructed by Messrs. Parsons were so designed that if the carbon brush became a thoroughly practicable proposition, the change could be made at very small expense, *i.e.*, sufficient surface was provided to enable carbon brushes to be used. No doubt it was a more difficult thing to design a continuous-current generator which would commutate satisfactorily with metal brushes than a machine using carbon brushes, and he could not help wondering whether the anxiety of some people to see carbon brushes used by everybody else might not be due to experiencing difficulties in designing dynamos which would commutate satisfactorily with brass-wire brushes, and he submitted that if a dynamo could be made which would commutate successfully with brass-wire brushes—and at present there was not the slightest doubt that it could be done—let them construct the machines for the moment with brass-wire brushes, and as soon as the ideal carbon brushes and holder came along then adopt the improved method of commutation. He would like to mention that they had in their works at present a large number of motors driving various machines, and the best commutating motors in the place were some comparatively old bipolar smooth core motors, built by Messrs. Crompton, and running with gauze brushes. They looked old-fashioned, and probably they were rather big for their output according to modern machines, and could not be built as cheaply as the modern motor, but, at the same time, for reliable running there was no motor in the works to equal them. He would like to correct one statement of Dr. Pohl's, who stated that the volts per segment were 50 in the only machines of which the figures were given. As a matter of fact, the value was 42 to 43 volts per segment, which was practically the same as Dr. Pohl had mentioned as being suitable. Dr. Pohl had raised the question of the size of exciter when using leakage paths and compounding. As a matter of fact, it was true that exciter magnets had to be somewhat larger, but the only thing this affected was the iron in the exciter magnets, and the iron of the exciter magnets was only a small proportion of the total cost of a large alternator. Copper was slightly increased by the amount necessary for the somewhat larger pole and the increased iron, so far as he could remember, did not exceed 50 per cent. at the outside. One point had been mentioned by Mr. Miles Walker and Mr. Clough in connection with the salient pole and barrel windings. One difficulty of the barrel windings was the end windings, which had to be supported by some form of gap unless the extremely ingenious arrangement shown by Mr. Walker was adopted. (Mr. Law here mentioned that the Chairman had reminded him that a similar arrangement had been invented by Brown years ago.) If this were done it was necessary to cool the windings under the cap, and that took away the possibility of cooling them along the barrel of the rotor. They could not have the same high density along the barrel and in the cap unless there were ventilation facilities. With regard to the time lag referred to in the exciter compounding, as a matter of fact there was no time lag in the exciter magnets with the leakage path compounding, for this reason, that the flux in the exciter magnets was almost the same, only in one case it passed through the leakage path, and when the load came on it was diverted and sent through the armature; therefore there was very little change in the flux in the magnets of the exciter, and consequently there was no time lag in the exciter. There was a time lag in the main motor magnets which would slightly delay the compounding action, but almost the same test mentioned by Mr. Walker had been applied to this winding. A lamp was put in a dark room and full load thrown on, but there was no flicker in the light whatever, so that, as far as that went, the time lag might be neglected.

Royal Institution.—Among the lecture arrangements after Easter are the following:—"The Development of the Modern Turbine and Its Application," by Mr. Gerald Stoney (two lectures); "The Scientific Work of Lord Kelvin" (with experiments and typical apparatus illustrative of his discoveries and inventions), by Prof. J. J. Larmor, F.R.S. (Friday evening discourse). Among succeeding Friday evening discourses will be one by Prof. Sir James Dewar, F.R.S.

A NEW METALLIC MIRROR FOR SEARCH-LIGHTS

EVER since the introduction of searchlights for battleships, attempts have been made from time to time to substitute metallic mirrors in place of glass ones, which are unsatisfactory, due to the fact of their being so readily broken by concussion when firing the guns, and that the silvering at the back of the mirrors is very liable to blister and leave the surface of the glass. The difficulty of making true parabolic mirrors has been overcome by the Cowper-Coles Electrolytic Process, which briefly consists of depositing by chemical means on the convex side of a glass former or mould a thin silver film and then spinning the former in an electrolytic cell charged with copper anodes and a copper electrolyte so as to deposit the copper on the silver surface, the process being continued until the silver film has received a sufficient thickness of copper to give the desired rigidity to the parabolic mirror. The glass mould and the electro-deposit are then removed from the depositing cell and placed in a vessel containing cold water, the temperature of which is gradually raised until the expansion of the copper is sufficient to cause the metallic mirror to leave the glass former. The silver-faced mirror thus produced has as highly polished a surface as the glass, and is finally subjected to an after-treatment to prevent the silver from tarnishing and then mounted in a metallic ring (which fits in the projector case) provided with knife edges, which firmly grip the edge of the mirror without distorting it. A large number of mirrors made by this process have been supplied to the British Government, some of which were sent out to the South African War.

Mr. Cowper-Coles is now introducing a new metallic mirror, which is only partially made by electro-deposition. The mirror has a surface composed of alternate bands or rings of gold and white reflecting surfaces which, it is claimed, give a more penetrating beam of light both at night and in foggy weather. Objects on which such a beam of light is thrown stand out in greater relief than in a light thrown from a silver white metal mirror, and the intensity of the light is so great that it is impossible to aim accurately at the projector. Another great advantage claimed for the new mirrors is that they are not fractured by concussion, and even when penetrated by bullets the area of distortion is very small.

Action against Marconi Co.—Before Mr. Justice Bigham, in the King's Bench Division on Wednesday and Thursday last week, an action by the Buitenlandsche Bank of Amsterdam against Marconi's Wireless Telegraph Co. to recover damages for an alleged breach of contract in connection with the erection of a number of wireless telegraph stations in the Dutch East Indies and the formation of a company to own and work the stations was heard. For the plaintiffs, it was stated that a year ago it occurred to some gentlemen acquainted with the Dutch East Indies that the islands afforded a good field for the operations of a wireless telegraph system, and they applied to the Dutch Government for a concession, and put themselves into communication with the defendants. The result was that in November, 1906, it was agreed between the plaintiffs and the defendants that the former should form a company under Dutch law with a share capital of about £200,000. It was also agreed that the defendants should arrange for the creation of 38 stations, and provide the necessary working capital of the new company up to £50,000. The concession was granted on June 5th, 1907, and according to Dutch law £1,000 had to be deposited, and 10 per cent. of the amount of the subscribed capital of the new company had to be paid. In the previous January the defendants had registered the Sanfil Co., and assigned to them any benefits they were entitled to under the agreement. The £1,000 required as a deposit was provided by the Sanfil Co., but the defendant company lent them the money with which to send the cheque. In the result the concession was cancelled, and the company came to nothing. Defendants said that they were not under any obligation to the plaintiffs until the Dutch East India Co. was formed and in a position to commence business, and that, as they had transferred their benfits and obligations to the Sanfil Co., they were under no liability to the plaintiffs. Mr. Justice Bigham, in giving judgment, said the defendants contended that under the contract they were to be released from liability if they formed a company and assigned to that company all their benefits and obligations under the contract. It was clear that the defendants formed a company called Sanfil, Ltd., and assigned to it all their benefits and obligations under the contract with the plaintiffs, and in his opinion the defendants were under no liability to the plaintiffs in respect of the failure to erect the telegraph stations and to provide the working capital for a company to be formed to take over and work the stations. Therefore, he entered judgment for the defendants, with costs. If the case should be taken further, and his decision was reversed, he assessed the amount of damages to which the plaintiffs would be entitled at £1,000.

CARS FOR UNDERGROUND ELECTRIC RAILWAYS

A LONG report on the design of car bodies for electric underground railways has been submitted to the New York Public Service Commission by Mr. Bion. J. Arnold, and is published in abstract in the *Street Railway Journal* (New York). The following analysis is given of the average time required under present conditions of working on the New York subway with cars of the type shown in Fig. 1:—(1) To open doors of cars after train has stopped—average, 2 seconds: (2) to unload an average of 163 passengers through 14 doors (15 to 20 seconds)

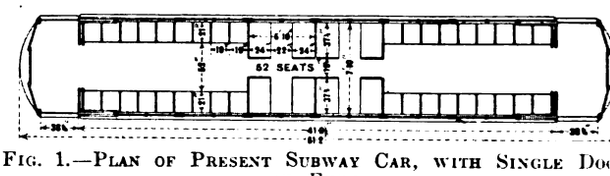

FIG. 1.—PLAN OF PRESENT SUBWAY CAR, WITH SINGLE DOORS AT ENDS.

—average 20 seconds; (3) to load an average of 206 passengers through 14 doors (15 to 30 seconds)—average, 20 seconds; (4) to close the car doors and give the signal by means of bell rope to motorman—average, 13 seconds; (5) total average time of express trains at station platforms between stopping and starting during the height of the rush hours—average, 55 seconds.

By means of the changes in car design recommended in the report, however, it is expected that the following schedule can be obtained without altering the conditions in other respects:—(1) To open doors after train is stopped, 2 seconds; (2) to

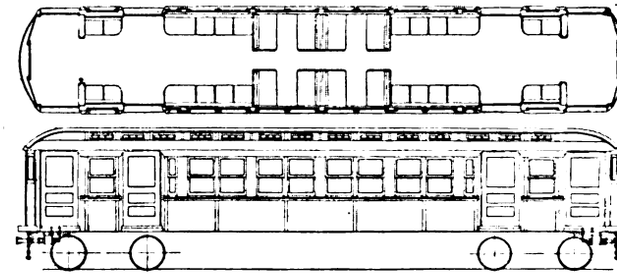

FIG. 2.—SUGGESTED ALTERATION TO EXISTING CAR BY THE ADDITION OF EXTRA DOORS NEAR ENDS.

unload 163 passengers through 14 doors and to load 206 passengers through separate doors, both processes being carried on at the same time, 20 seconds; (3) to close doors and give signal to motorman, 8 seconds; (4) total average time of trains at express stations during rush hours should not exceed 30 seconds.

In a general consideration of the question, the following requirements are laid down for successful working:—(1) Separate entrances and exits; (2) a space which can be cleared so as to be ready to quickly receive the passengers boarding a car; (3) convenient means of circulation inside the car; (4) standing room space contiguous to the exits; (5) as many cross seats as

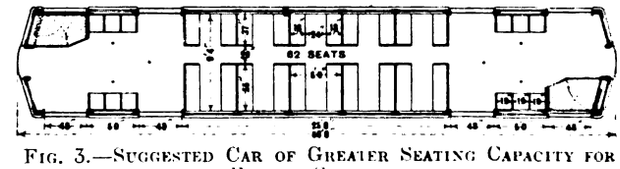

FIG. 3.—SUGGESTED CAR OF GREATER SEATING CAPACITY FOR FUTURE SUBWAYS.

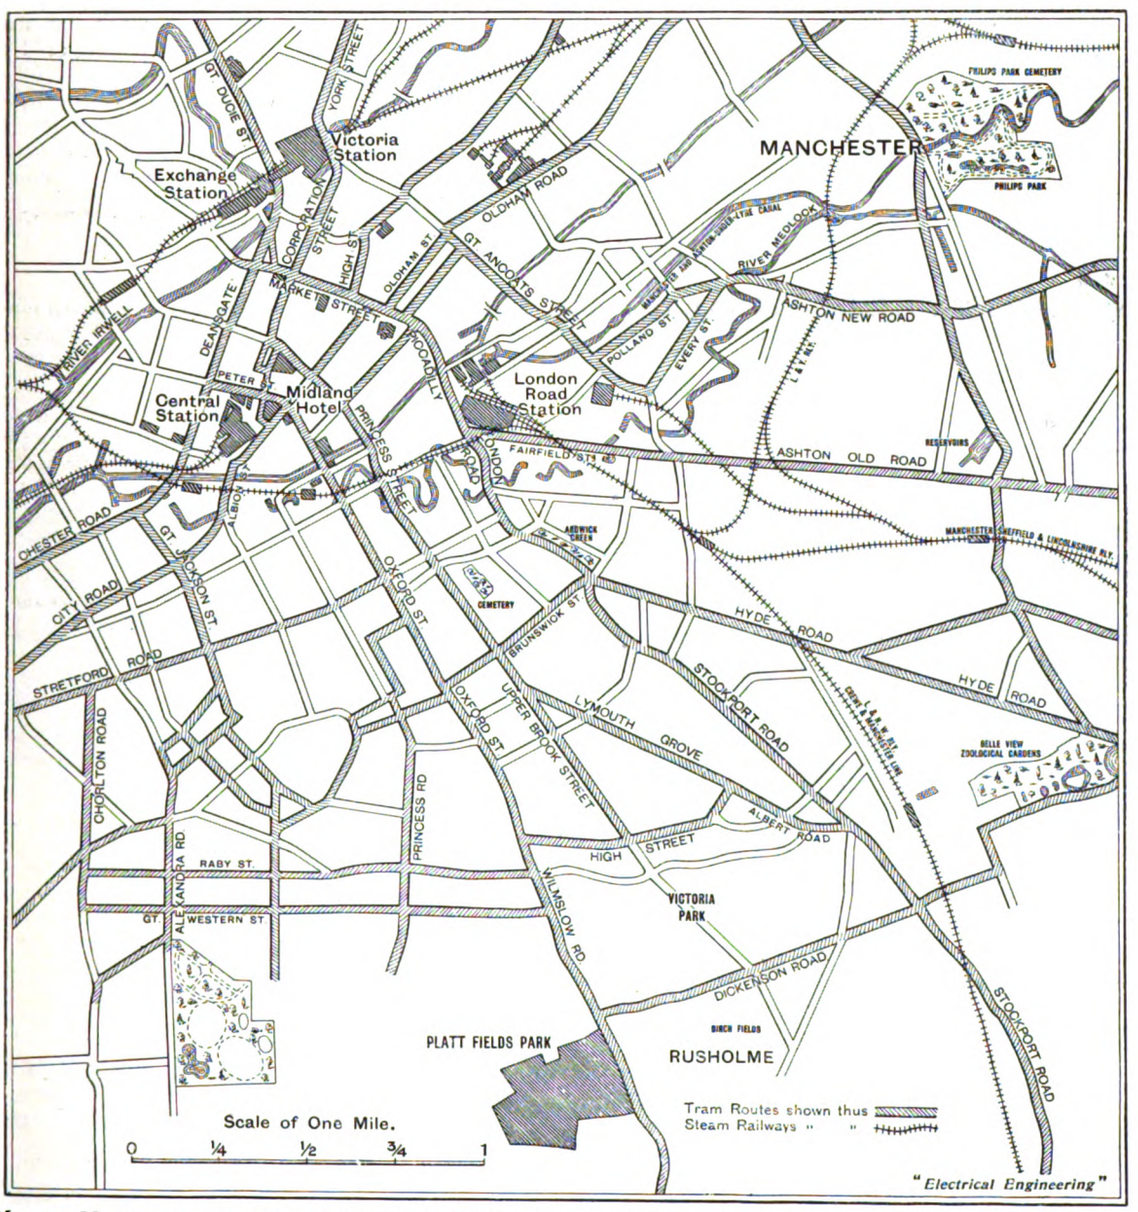
practicable; (6) exit and entrance doors sufficiently removed from each other to allow for the car stopping convenient to guiding rails on the platforms; (7) doors located so as to minimise the danger from open spaces at curve platforms.

A number of types of car in use in America are then considered in some detail and compared, including cars with central side door and end doors, cars with two quarter side doors, cars with three doors near centre, cars with multi-side doors, and cars with double doors near ends.

The final course recommended is the alteration of the existing cars in the manner shown in Fig. 2, by introducing additional side doors, one near each end of each side of the car, and as near as practicable to the present end doors, the distance between the doors being at least sufficient to furnish a pocket for the sliding doors. These additional doors can be added without

Digitized by Google

disturbing the present seating arrangement of the car to any great extent. It is true that the introduction of these doors will make it necessary to remove eight seats from each car, but the operation of the cars in actual service will make it possible to pass so many more cars through the subway that the loss of eight seats in the added cars, and the extra standing room, so convenient to the separate exit, is a feature which will decrease the station waits and thereby increase the schedule speed.



The new doors can be used for exits, and the present end doors for entrances, thus providing at once the means of carrying on the process of unloading and loading simultaneously and without the present conflict which during rush hours has become so objectionable. This car provides a separate space for leaving passengers to collect around the exit doors without blocking the space which should be provided for the passengers entering the car. The result will be that passengers will move in and out much more quickly than at present, and the movement of passengers into the car will facilitate the movement of passengers out of the car.

An advantage over cars with central doors is that the exit and entrance doors are both directly under the eye of the gateman, who can accentuate the circulation by opening the exit door slightly in advance of the entrance door, which can be done by mechanical or pneumatic means.

The seating capacity in future cars of the same overall dimensions, and with the arrangement of doors described, could be increased from 44 to 48 by the provision of more longitudinal seats. But for future subways, the wider type of car, shown in Fig. 3, is recommended.

THE MANCHESTER ELECTRICAL EXHIBITION

In our last issue we announced that final arrangements had been made as to the place and date of the Manchester Electrical Exhibition, which is to be held from October 3rd to October 31st, in special buildings to be erected at Platt Fields Park, Fallowfield, and we are able this week to reproduce a map of Manchester, showing the position of the site in relation to the principal railway stations and tramway routes. This site, which is in the important residential district of Fallowfield, has been offered rent free by the Manchester Corporation, and is easily accessible by tramcar from the centre of the city. The special building which is to be erected is to cover a space of somewhat over one hundred thousand square feet.

Sketch Map of Manchester, showing Position of Exhibition Site at Platt Fields Park, and Principal Tramway Routes.

E

Digitized by Google

As already announced, arrangements have been made with the Electricity Committee of the Manchester Corporation for a full supply of the necessary electrical energy. We now understand that the charge to exhibitors for lighting (at 200 volts continuous current) will be 2d. per unit, and that the rate for power (at 400 volts either continuous or three-phase, or for motors of less than 3½ h.p., 200 volts continuous) will be 1d. per unit. The rent for meter and necessary fuses will vary from one to two guineas, according to the size demanded.

Having regard to the fact that the exhibition is to be held in Manchester, it is proposed to invite manufacturers of textile and mining machinery to be represented, and to arrange for various exhibitors to have working exhibits of such machinery, and owners of works, mills, factories, and mines (of which there are a vast number in the north) will be able for themselves to see exactly how electricity can be applied to the business in which they are interested.

Intending exhibitors are asked to write to this effect at the earliest possible moment, giving some idea as to the amount of floor space that they would desire to occupy, and the class of goods they would show. This will assist in securing a favourable position, and will also assist the committee in arranging the final details of the building, a plan of which, together with rules, regulations, and application form attached, will be circulated.

The profits of the exhibition will be distributed by the committee as follows:—(1) In a percentage return to exhibitors; (2) in a percentage return to contributors and donors; (3) contributions to charities connected with the electrical industry, and the surplus, if any, to be specially dealt with by the committee as they think fit.

NEW TRAMWAY TRACK WORK IN NEWCASTLE-UPON-TYNE

THE vigorous expansion of Newcastle does not appear to be affected by such temporary considerations as engineers' strikes, if one may judge by the remarkable progress which is being made in city improvements. At the present time a new thoroughfare is being opened up in the heart of the city, which will in course of time become one of the main arteries of the commercial portion of the metropolis of the north.

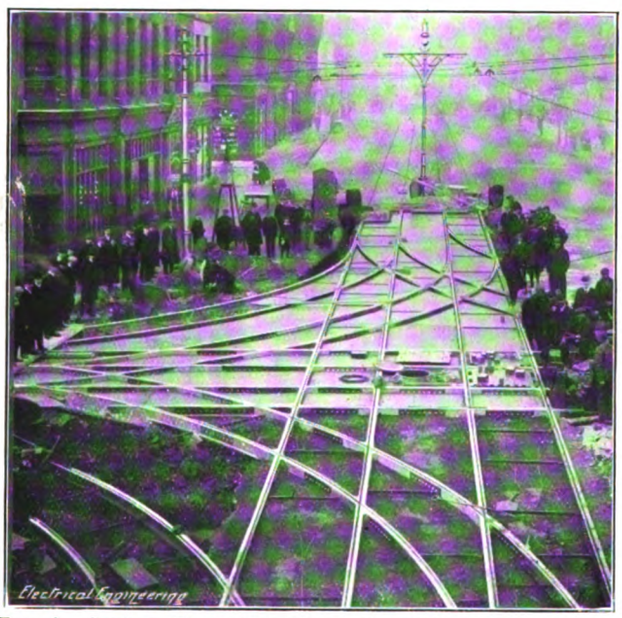


Fig. 1.—Special Tramways Junction at Market Street and Pilgrim Street, Newcastle.

Along this extension, which will possibly be called New Market Street, the tramway authority has already decided to make provision for tramway service, and as a result of this decision it has become necessary to materially alter the permanent way in one of the busiest streets of the city.

A large tramway junction measuring 148 ft. by 143 ft. is being placed at the intersection of Pilgrim Street and Market Street, containing curved tracks on three sides of the main diamond crossing, which is almost at right angles. The total number of crossings is 30. Messrs. Edgar Allen & Co., Ltd., of the Imperial Steel Works, Sheffield, provided all the work for this lay out, executing it in manganese steel throughout. So far as it is known it is the first time that cast manganese steel rails have been used throughout in such a large junction of this nature.

It was decided to place the work down in position, and for this purpose it was necessary to divert four lines of tram routes. Gangs of workmen were placed in continuous night and day operation on the change-over work, the day gang numbering about 50, the night gang 20. In order to facilitate the operations of the latter a series of five enclosed arc lamps were connected by means of a bamboo pole and hook arrangement to the existing trolley wires and to earth, giving an excellent general illumination, and materially assisting operations. As a result, the whole work, involving

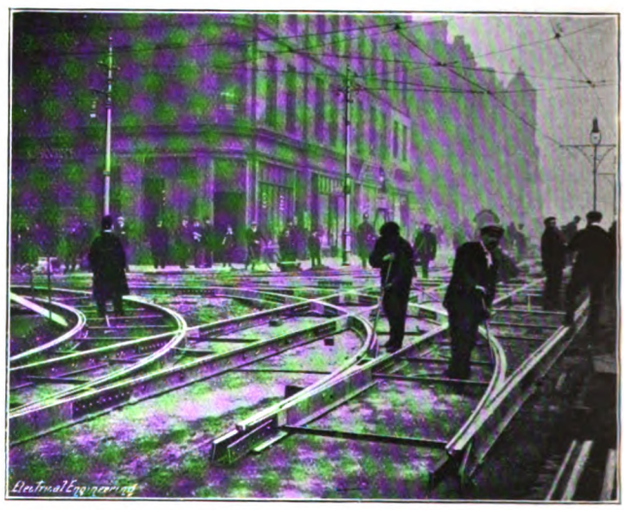

Fig. 2.—Special Junction in Process of Construction.

the diversion of traffic, including the laying of between 400 and 500 square yards of concrete, the steel work, and the filling in of wood pavement, has been accomplished in the exceptionally short time of one week. The credit of this performance is due to the excellent organisation of the City Engineering Department, under Mr. Kirkpatrick, who carried out the work of laying the junction, and the smartness of this achievement is emphasised by the fact that it was necessary to allow certain work connected both with the electric lighting and other companies' mains to be carried out before the completion of the undertaking. As a result, Newcastle will be equipped with one of the finest examples of junction work in the United Kingdom, and the efficiency of manganese cast steel for permanent way construction will be admirably demonstrated. The first illustration which we produce by courtesy of the City Engineering Department conveys an idea of the extent of the work undertaken. The second shows some of the work in course of construction.

THE ALDWYCH EMBANKMENT L.C.C. TRAMWAY SUBWAY

THE extension of the Kingsway tramway subway from Aldwych to the Embankment, which forms the connecting link between the northern and southern systems of the London County Council tramways, is now complete, and will be formally opened to-morrow, when a special inspection of the subway will be made.

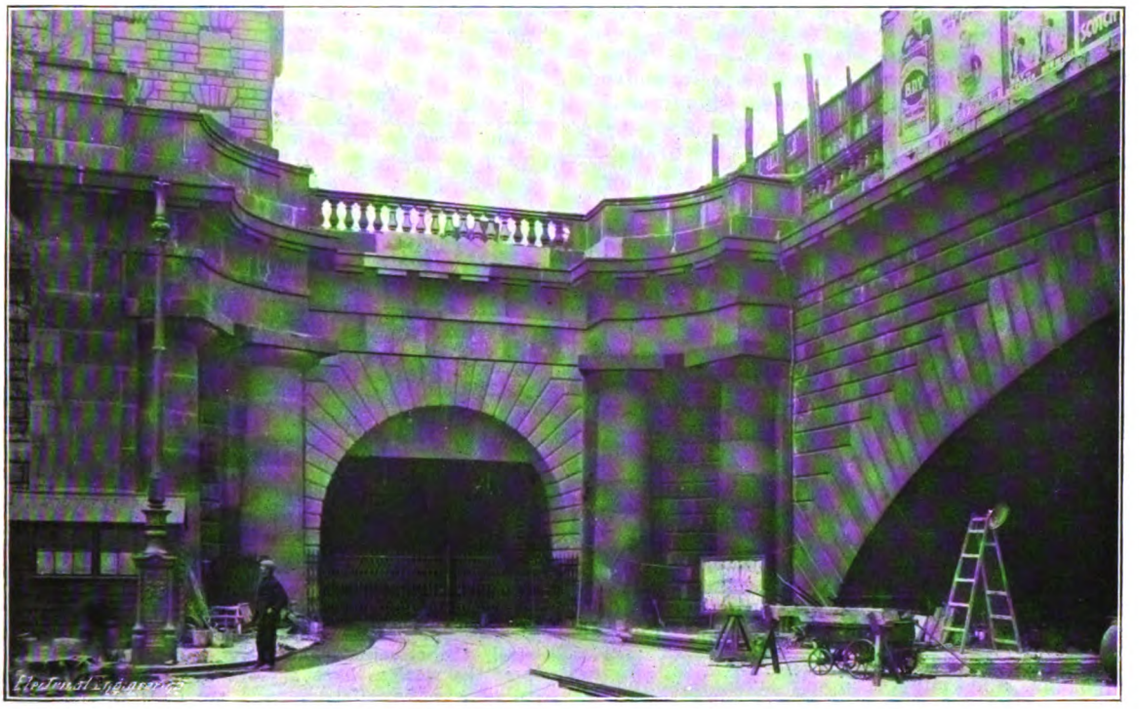

Fig. 1.—Entrance to Subway from Embankment.

Visitors will assemble at the London Day Training College, Southampton Row, at 3 p.m., and will proceed to the Holborn subway station, whence they will proceed by special car through the subway, along the Victoria Embankment, and over Westminster Bridge on an inspection of a portion of the southern system, travelling thence through the subway to the "Angel," Islington, and returning to the Holborn subway station at about 4.30 p.m.

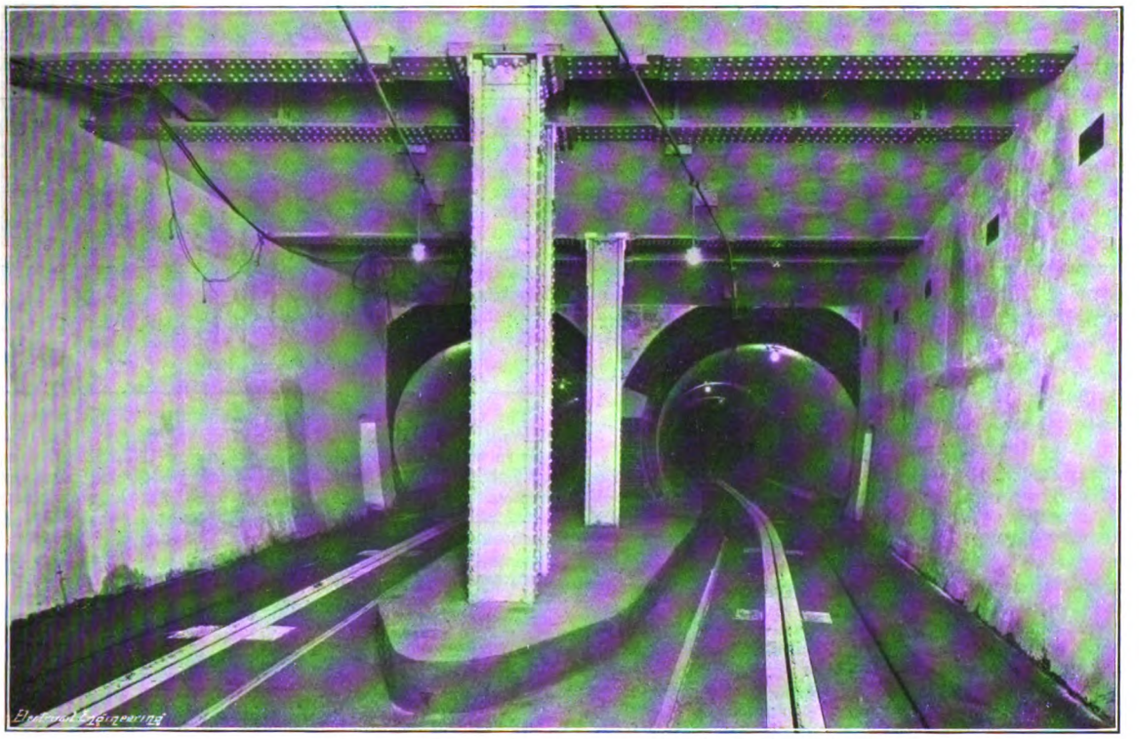

Fig. 2.—Interior of Subway at Entrance of Twin Tube Tunnels.

The main features of the subway and the special form of conduit tramway construction were dealt with pretty fully in an illustrated description in Electrical

Digitized by Google

Engineering, March 5th, page 343, when the work was in progress, and we are now able to reproduce a couple of special photographs showing the appearance of the completed subway. Fig. 1 is a view looking across the Victoria Embankment, and showing the entrance to the subway by the side of Waterloo Bridge. Part of the special work of the junction with the Embankment line is seen in the foreground, and the rearrangement of the old stone pillars, &c., in forming the new arch is clearly shown. Fig. 2 is from a photograph taken inside the subway at a point under Wellington Street, about halfway between the Strand and the beginning of Waterloo Bridge, looking in a northerly direction. This shows the point of transition from the double-track form of subway with girder construction to the twin cast-iron tubes through which the lines pass under the Strand to join the double-track section lined with concrete under Aldwych. These tubes are 14 ft. 11 in. in diameter, and this is sufficient to allow even on the curved portion a clearance of 2 ft. all around to cars.

The special form of conduit construction used in the subway was fully described by the aid of detailed drawings in the article already referred to, and the photographs now given serve to illustrate the different arrangement of the slot. The arrangement at the entrance to the subway and across the road seen in Fig. 1 is the standard road construction as used elsewhere in the L.C.C. tramway system, while in Fig. 2 the special construction employed within the subway, where the weight of ordinary wheeled traffic has not to be borne, is shown. In this latter arrangement the standard fixed slot rails are replaced with iron covers 5½ in. in width, of a special bulb angle section laid in short lengths, and supported by special shaped castings at the ends. These can be easily taken up at any time, and uncover practically the whole width of the conduit. Another important difference is the absence of the heavy cast-iron yokes used in the standard construction. Detailed sectional drawings of the two arrangements will be found in Electrical Engineering, Vol. I., page 9, in connection with the Embankment line, and the article on the subway extension in the issue of March 5th, page 343. The double-truck single-deck all-steel cars that will be used on the through routes passing through the subway have already been in use in the older part of the subway and other parts of the system. Their overall length is about 33 ft., and they accommodate 36 passengers. The whole of the track and conduit equipment, and also the construction of the subway, was carried out by the Works Department of the London County Council to the design and under the direction of Mr. Maurice Fitzmaurice, C.M.G., Chief Engineer to the Council, to whom we desire to express our thanks for permission to take photographs in the interior of the subway. The laying of the cables and other electrical details have been under the supervision of Mr. A. L. C. Fell, Chief Officer of Tramways.

Light Railway Order.—The Board of Trade has confirmed the London United Tramways Light Railways (extension of time) Order, 1908, amending the London United Tramways (Light Railway Extension) Order, 1904.

Institution of Electrical Engineers. The following is the result of the ballot for new members at the Institution on Thursday:—Associate Members: L. C. Bose, A. R. Gundry, H. F. Haworth, F. A. King, G. Lloyd-Jones, W. T. MacCall. Associates: F. Berry, A. E. Kiralfy. Students: J. R. Abbott, A. N. Aikman, A. J. Airston, C. G. Barker, R. F. Blackmore, S. H. Bridcut, H. Brittan, W. A. A. Burgess, G. W. Burley, H. Ching, J. Claughton, J. Davies, A. E. H. Dinham-Peren, S. Dudman, K. N. Eckhard, A. C. Evans, W. A. Fletcher, W. B. Garrett, B. C. Gupta, L. G. Harris, C. D. Hayhurst, C. H. Hayward, H. C. Heath, L. R. Hickman, A. R. Hinde, D. W. J. Janes, W. G. Johnson, G. H. Landon, F. C. Lunnon, G. M. Meyer, P. Nutter, D. A. Pearson, G. F. H. Satow, E. S. White, A. M. Willis.

GERMAN ELECTRICITY SUPPLY STATISTICS

A recent issue of the *Elektrotechnische Zeitschrift* contains the statistics of the electricity works in Germany, which are published annually in that journal. According to these statistics, there were in April, 1907, 1,526 generating stations in operation as against 1,334 in the previous year (see Electrical Engineering, Vol. I., p. 733), an increase of 192 as against an increase of 163 between 1905 and 1906. The following tables summarise the information contained in the statistics, and give a good idea of the extent to which the various systems of generation and distribution are in use in Germany:—

Table I.—*Systems of Supply.*

System.	Number of Stations.	Plant capacity, kw. Generators.	Plant capacity, kw. Accumulators.
Continuous current	1,217	178,169	64,853
Single and two-phase...	41	26,201	115
Three-phase	129	151,123	1,536
Combined three-phase and single or two phase	2	975	14
Combined continuous current and single or two-phase...	19	13,828	2,838
Combined continuous current and three phase	116	334,492	58,146
Combined continuous current and alternating (single and polyphase).	2	25,963	588
Totals	1,526	730,751	128,090

Of these 1,526 stations, 1,025 are under State or municipal control, the remaining 501 only being under private control. 634 of the stations have a plant capacity (including accumulators) of less than 100 kw., 625 are between 100 and 500 kw. capacity, and 165 are between 500 and 2,000 kw. Of the 64 stations of over 2,000 kw. capacity, 12 have a capacity of over 10,000 kw. The Berliner Elektricitäts-Werke heads the list with a total capacity of 138,700 kw., which is the combined plant capacity of the six generating stations in Berlin, exclusive of the new 12,000 kw. station at Rummelsburg.

Table II.—*Motive Power.*

Motive power.	Number of stations.	Plant capacity, kw.
Steam engines	669	544,581
Water power	161	16,352
Gas and oil engines	210	25,089
Water power and steam engines ...	288	116,088
Water power and gas or oil engines ...	86	6,681
Steam and gas or oil engines	53	15,952
Steam, gas or oil engines, and water power	27	5,263
Electric power (from another station)	32	745
Totals	1,526	730,751

The total lamp connections amount to 486,828 kw. for incandescent lamps, and 89,456 kw. for arc lamps. The total horse-power of motors connected amounts to 582,862 h.p., equivalent to 524,577 on the assumption of 900 watts per horse-power connected. This gives a total of 1,100,861 kw. connected. The total plant capacity for the 1,526 generating stations, including accumulators, is 858,841 kw.; or 0·78 kw. of plant per kw. connected. It is interesting to note that of the 1,526 generating stations in operation in 1907, over 1,100 were less than ten years old. At the end of the year 1888 only 14 stations were in existence, but the number rapidly increased from that date. In the year 1900 alone no less than 144 new stations were set in operation, this being the maximum number for one year.

Electrification of the Swedish State Railways.—The sum of £210,000, which was granted for the purchase of water-power rights, has already been expended, and the Railway Administration have asked for a further grant of £270,000. The generating stations which will be erected at the waterfalls will give a supply for industrial purposes as well as for the State Railways.

THE ELECTRICAL EQUIPMENT OF THE "MAURETANIA"

MR. W. C. MARTIN read a paper last Friday before the Institution of Engineers and Shipbuilders in Scotland in which he described the electrical equipment of the Cunard steamer *Mauretania*. Before proceeding to details, he outlined the general history of electric lighting on board ship from the first vessel to be fitted, the American steamer *Columbia*, the lighting of which, by 115 10-c.p. lamps, was carried out under the direction of Mr. Edison in 1880. In order to give some idea of the great progress this branch of electrical engineering has made within the last 26 years, he mentioned that the total cost of the installation on each of the latest Cunarders was £65,000.

Generators.—In the *Mauretania* the total output of the four electric generators is about 2,200 E.H.P., while the actual power required for all the lights and motors running at one time is 2,773 h.p. It is found in general practice that, the power being very intermittent, two generators are capable of doing the work, thus leaving a large margin in hand for emergencies. To find space for such powerful plant and to fit the installation on the safest and most reliable system, presented some interesting problems. The first of these was to determine the most suitable type of steam generator. After due consideration, the Cunard Co. and the builders of the vessel decided to adopt the steam turbine, by the use of which the space required was reduced to a minimum, with less weight and more freedom from noise or vibration as compared with ordinary high-speed engines. There are four sets of Parsons' turbo continuous-current generators. Each dynamo is shunt wound and is capable of giving an output of 3,750 amperes at 110 volts and 1,200 revolutions per minute. These generators are placed on an elevated platform abaft the engine-room, in two separate compartments divided by a water-tight bulkhead and arranged so that, in the event of either dynamo room being flooded with water, the ship could still be lighted from the unflooded side. A better arrangement for the generators would have been to place them nearer the centre of the ship, but being a vulnerable part, the Admiralty required them to be placed below the water line, hence the reason for placing them so far aft.

Main Switchboard.—To control this great power with safety and efficiency in a confined space exposed to a high temperature and possible trouble from vibration, required controlling switchgear of a substantial design, yet sensitive in action. The main switchboard, Fig 1, is divided into two parts, one section being erected in the port generating room and the other in the starboard generating room. Each board has two generator panels, 12 feeder panels, and one disconnecting panel. Normally the two switchboards are connected together as one board through the disconnecting switches, but may be separated in a moment from *either* room, and each side of the ship operated as a separate installation. The use of fuses for the control of the large currents dealt with would have been inconvenient and unsafe, and instead automatic circuit-breakers (performing the function of both switch and fuse) were fitted. These circuit-breakers are of massive construction, the contact surfaces being pressed firmly together by levers. The make and break contacts are massive carbon blocks, at the extremity of the switch arms, and the main circuit-breakers are so arranged that the flash at breaking takes place in fire-proof compartments well clear of the attendant. To accomplish this object and to make the operation of the switches easy, the handles are placed below and connected to the switches by insulating links behind the board. These switches are held in the closed position by engaging with a trigger which may be released either by hand or by a trip coil. In order to prevent the opening of the circuit breakers during a momentary overload, a relay is introduced which closes the trip-coil circuit when an overload occurs, after a period adjustable up to 15 seconds. Should, however, a reversal of current through the generator take place, the relay promptly closes the trip-coil circuit and thus cuts the machine out of circuit. The opening of the circuit-breaker in turn breaks the trip-coil circuit, and prevents damage to the coil or waste of energy. The feeder switches are operated in a similar way, but without the reverse current arrangement. They have, however, in addition, a trip coil in series with the main current, adjusted to open the circuit with a greater current than the relay is set to operate at, but instantaneous in action. Thus, should a short circuit or heavy overload occur, and the relay fail to operate, damage to the cables and machinery is effectively prevented. The relay is simple and reliable in operation. It consists of a small motor, similar to that used in meters, through which part of the current is shunted. This motor tends to wind a strong silk cord on to a drum against the pull of a weight fastened to the other end of the cord. The cord passes round a drum to which the contact arms are fitted. When the current exceeds the overload limit, the torque of the motor is sufficient to wind up the cord, and thus close the trip-coil circuits. The adjustments are affected by altering the weights and varying the distance between the contacts.

All the ammeters and voltmeters are of the moving coil type, the former being operated from shunts in the main circuits. By this means it is possible to have the reading instruments in any convenient place, and in the *Mauretania* two instruments are fitted for each machine, one being in the port and one in the

starboard room. On each board, one additional ammeter is fitted, connected to bars behind the feeder panels, and so arranged that it may be connected by a plug to any one circuit at a time. By this means the current in any feeder may be ascertained without the expense of separate instruments for each circuit. Two station voltmeters and two paralleling voltmeters are provided, and the shunt regulators, which are placed behind the boards, are operated by a hand wheel on the front.

Main Cables.—The Cunard Company, with their usual precautions for the comfort and safety of their passengers, decided that a high voltage would not be advisable, which accounts for the current being generated at only 110 volts. This necessitated cables of a great carrying capacity, and also very heavy switch gear. The Admiralty further required all main cables to be run under the water line, and to accomplish this it was necessary to utilise the only available spaces in the coal bunkers or through the boiler rooms. Those who have had experience in the lighting of ships will know that these spaces generally are most objectionable for electric wires, especially the coal bunkers. The high temperature of the boiler-room, and the very large cables necessitated special precautions being taken to prevent the heat softening the insulation and allowing the cable to sink through the rubber, causing a short circuit. With

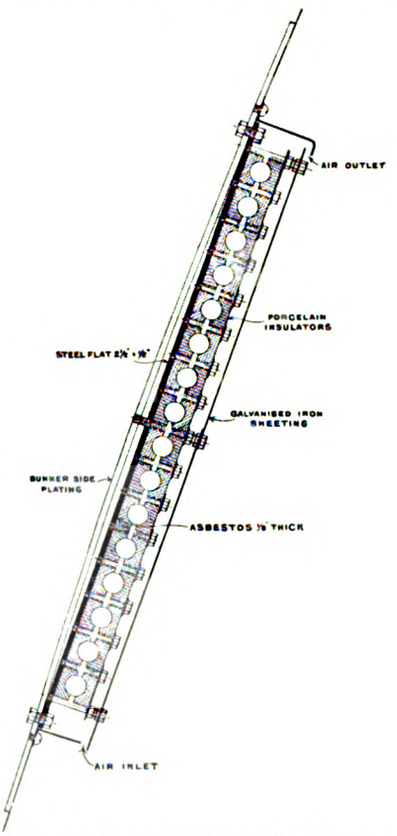

Fig. 2.—Rack for Main Cables on Bunker Side Plating.

ordinary armoured and lead-sheathed cables, the heat would readily affect the insulating materials. It was, therefore, necessary to adopt fire-resisting covering as well as the usual vulcanised rubber, so that in addition there is a heat-resisting compound and an outer covering of two coats of asbestos braid fitted on the cables. Fig. 2 shows the method of fixing and protection of cables. The double wire system is used throughout, and there are 48 main cables of about 2 in. external diameter running from the generating station to the various sections of the ship, Fig. 3. The power is divided into 24 sub-stations of approximately 100 h.p. each, 12 of these being on the port side of the ship, and 12 on the starboard side. Eight of these stations provide power for forced draught fans, two to supply the engine-room machinery, and two for engine-room lighting, the remaining 12 being connected to auxiliary switchboards at convenient distributing centres throughout the ship.

Auxiliary Switchboards.—These 12 auxiliary switchboards are placed directly opposite each other, port and starboard, and cross-connecting cables are fitted so that, in the event of one section failing, the supply can be maintained from the other side. It should be mentioned here that, as the motors are only used intermittently, there is always sufficient surplus carrying capacity in the cables to provide for emergencies of this nature, thus guarding against any total extinction of the light. The auxiliary switchboards are fitted in fireproof chambers, prin-

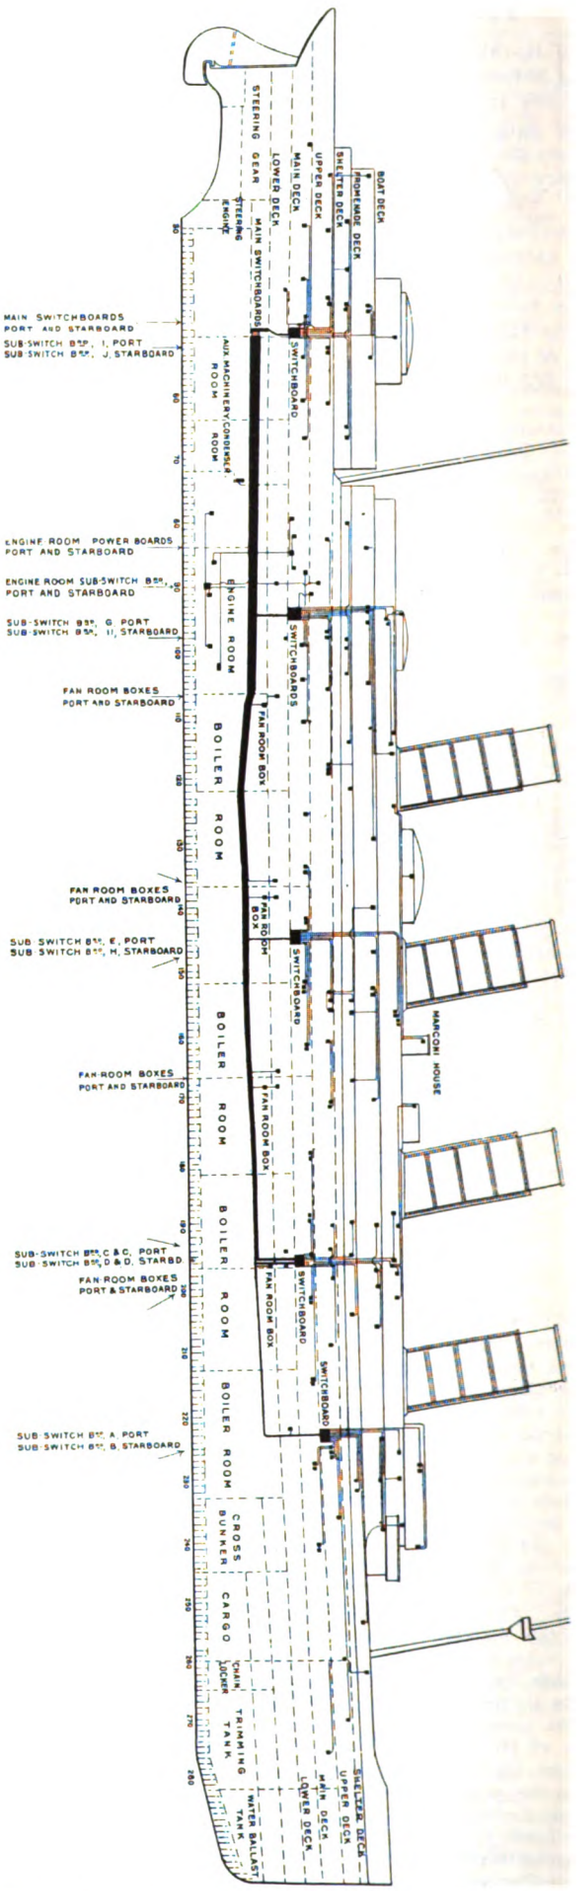

Fig. 3.—Elevation of R.M.S. "Mauretania," showing Position of Main Cables, Switchboards, &c.

Digitized by Google

cipally on the main deck. The switches are single pole, and the fuses double pole—Mr. Lackie's patent zinc fuse—which breaks circuit with a minimum flash. Each board is provided with a spare panel containing spare fuses ready at a moment's notice.

Branch Cables and Wires.—From these auxiliary switchboards vulcanised rubber cables are carried in wood casings to section fuse boxes, which again provide distributing boxes at convenient positions for supplying the lights, the wires being run without joints. It will be noticed that these cables running from the main deck to the different sections above are like the trunk of a tree, with branches spreading out to the different decks. Special precautions were taken to keep all positive and negative wires in separate grooves. In the corridors the casings are arranged so that all wires are accessible at all times. In all the rooms of the ship the frieze forms a covering to the electric casings. No fuse boxes have been fitted, but all fuse panels are built in specially arranged recesses in the panelling, the panel itself forming the door; a door is also fitted behind for access to the wires. Inside the door, a tablet or card is fitted, giving information of what each branch supplies, with size of fuse.

In the wiring of engine and boiler spaces, and other parts of the ship exposed to rough work, the protection of the branch wires calls for special treatment. Some engineers think screwed iron conduit or galvanised iron tubes are most suitable, but experience has proved that tubes sweat and retain condensed moisture, which very soon destroys the best insulation. The best results are obtained with parallel twin conductors, each conductor being separately insulated with pure rubber and vulcanised rubber, braided and bound together, then sheathed with an outer armour of galvanised iron wire. This system of armoured twin conductors has special advantages for engine rooms and other exposed parts. It is compact, requires less space, and has as strong a mechanical protection as an iron tube, but does not harbour moisture about the insulation as in the case of tubes. When well coated with paint the armouring is further protected from corrosion. It is water-tight and fireproof, has no soldered joints, and is always accessible. In addition to the lighting and power circuits, there are single core and multiple core cables for electric bells, telephones, fire alarms, electric clocks, and the Stone Lloyd system of indicating the position of water-tight doors. These cables are too numerous to give in detail. There are over 200 miles of wire fitted, the copper in which weighs over 100 tons.

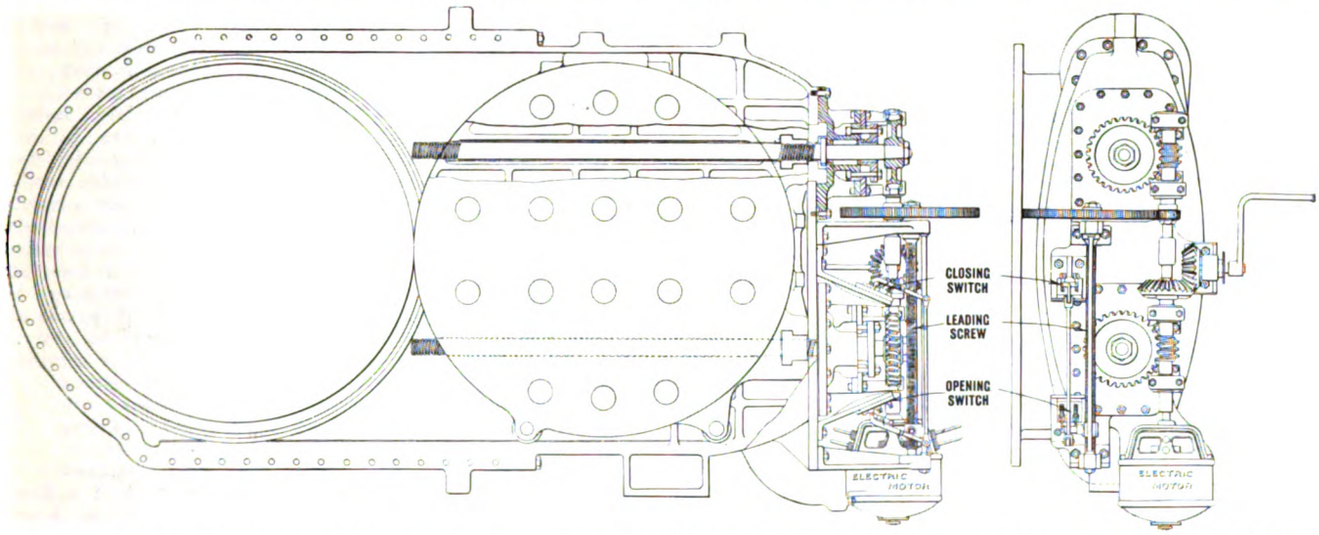

Fig. 4.—Electrically-operated 75-in. Sluice-valve. Closed by Motor Running at 1,150 r.p.m. in 2 minutes. Closed by Hand in about 146 Minutes.

Electric Lighting.—There are over 6,300 lamps distributed over the ship, fitted to pendants, electroliers, and brackets of various designs to suit the furnishings of the respective rooms. In the public rooms and state rooms the fittings are of a most handsome design, and the arrangement of concealed lamps for lighting the dining saloon dome gives a beautiful sunlight effect, while other compartments are brilliantly illuminated with beautiful crystal fittings. A special feature throughout has been to design the fittings so as to obtain reflected lighting from the ceilings as well as from the lamp itself.

Electric Power and Heating.—The Cunard Company and their engineers realised that if steam were used for auxiliary work the loss through condensation in the enormous lengths of steam pipes would be very great, and also that the annoyance to passengers would be unbearable. They therefore took full advantage of the simple and more economical method of distributing the power electrically throughout the ship.

In this installation there are :—16 motors aggregating 800 h.p. for forced draught; 28 motors aggregating 276 h.p. for ventilating of machinery space; 18 motors aggregating 400 h.p. for auxiliary machinery in engine-room; 16 motors aggregating 52 h.p. for ventilating the ship; 53 motors aggregating 156 h.p. for the thermotanks supplying heated air; 4 motors aggregating 64 h.p. for refrigerating machinery; 2 motors aggregating 16 h.p. for two passenger elevators; 4 motors aggregating 108 h.p. for lifeboat winches; 8 motors aggregating 48 h.p. for electric jib cranes; 6 motors aggregating 78 h.p. for mails and baggage hoists; 6 motors aggregating 20 h.p. for hoists and stores; 2 motors aggregating 10 h.p. for printing machinery; 1 motor aggregating 5 h.p. for wireless telegraphy; 20 h.p. for pantry and kitchen service machinery and hot plates; 80 h.p. for 106 electric radiators for special state rooms, bath rooms, and hospital. This makes a total of 2,133 h.p. independent of the supply for lighting.

The forced draught for the main boilers is supplied by 32 fans arranged in pairs, and driven by 16 electric motors of 50 h.p. each; the motors are of the enclosed type, developing the power at 450 revolutions per minute, with the current at 110 volts. The fan impellers are of the single inlet type, being 66 in. in diameter, and each capable of delivering 33,000 cubic ft. of air per minute, against a water pressure of 3¼ in. on the discharge side when running at 450 revolutions per minute. Owing to the high temperature in which these motors have to work, a very ingenious arrangement is provided whereby they may be cooled. Situated between the motor at the commutator end and one of the 66-in. fans, is an auxiliary fan with separate casing, the disc being 48 in. in diameter, and made of sheet brass. The discharge is connected to the under side of the motor and plate, the air being circulated round the commutator and armature, and leaving at the opposite end. Each fan is provided with a water-gauge and tachometer. Each motor is also fitted with a controller or switch capable of regulating the speed in equal increments by field variation from 225 to 450 revolutions per minute. Low voltage and overload automatic releases are fitted to these controllers, giving complete protection to the motors under all conditions. When running at the lowest speed the approximate output of air from each fan is 17,000 cubic ft. per minute, against a water pressure of 1 in. Each fan room is also ventilated by eight single inlet fans 21 in. in diameter, each being driven by a motor of the totally enclosed type, capable of delivering 1,000 cubic ft. of air per minute against a water pressure of 1 in., when running at a speed of 900 revolutions per minute. The motors are of the four-pole series wound type, and are each capable of developing normally an output of 5 h.p. when supplied with current at a pressure of 110 volts, and running at a speed of 900 revolutions per minute. Each motor is supplied with a controlling panel consisting of a one double-pole quick-break switch, tubular fuses, and starting and regulating resistances, the whole being self-contained and mounted upon a panel suitable for erection on the bulkhead.

In the engine-room the electric motor performs a most important part in the manipulation of the main turbines and other gear. For dismantling the turbines there are six sets of lifting gear, each consisting of a 30 h.p. motor, driving a horizontal shaft above the turbine, coupled to two seven-inch diameter

Digitized by Google

vertical lifting screws and worm gear, by which means the turbine casing or rotor can be lifted in turn. The weight of the L.P. rotor is about 125 tons and the H.P. rotor 72 tons, and these can be lifted in 30 minutes.

One of the best illustrations of the adaptability and usefulness of electric motors on board ship is to be found in the case of the electrically-controlled sluice valves. There are two 75-in. and two 60-in sluice valves in connection with the high-pressure turbine exhaust steam, and in each of these is fitted a 12 h.p. motor operating a worm gear, as shown in Fig. 4. Each is controlled from switches, Fig. 5, on the starting platform, where an index shows the action of the valve. The fact that the valves can be closed in a minute or two by the electric motor, and that it would take four men 2½ hours to close it by hand, shows a remarkable saving in time and labour in favour of the electric motor. Other useful applications of the electric motor in the engine-room is the 30 h.p. motors installed for the turning gear, and 25 h.p. motors which drive centrifugal pumps drawing off surplus water from the condensers. For ventilating

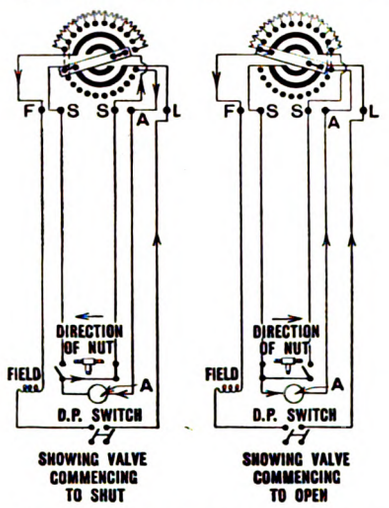

Fig. 5.—Diagram of Connections for Sluice-valves.

the engine-room there are 10 Sirocco fans of 25 in. diameter, each driven by a 5 h.p. motor; six fans of 30 in. diameter, each driven by a 30 h.p. motor; and four fans of 15 in. diameter coupled to 1½ h.p. motors.

The general heating and ventilating of the ship is maintained by 53 thermotanks, each fitted with a motor-driven fan, the motors varying from 2½ to 4 h.p., making a total of 156 h.p. Each motor fan supplies a section of the ship with warm or cold air, or, by arrangement of valves on the tanks, the fans can be made to extract the air from various compartments.

Deck Winches and Other Appliances.—Electric power driving is also extensively used for deck winches, passenger hoists, and other appliances to the extent of 270 h.p. For the passenger lift two motors of 8 h.p. supply the power to the winding gear, while other two motors of 15 h.p. supply the power for two 40-cwt. baggage hoists, and two 5 h.p. motors operate two 10-cwt. store hoists, while two more of 1½ h.p. control the two 2-cwt. pantry hoists for conveying food from the kitchen. There are also two mail hoists fitted with 12 h.p. motors (see Electrical Engineering, Vol. II., p. 885). In addition to these there are four electric jib cranes, each made to lift 12 cwt. The lifting motions are operated by a 12-h.p. motor through worm gear, and the slewing motion through worm and spur gearing by a 2½-h.p. motor, the motors being series wound of the enclosed type. These cranes do their work absolutely without noise of any kind and are conveniently placed on the boat deck for lifting stores, or luggage and mails, from tenders that come alongside. Another important part performed by electric power is the hoisting and lowering of the lifeboats. This work is done by four electric winches placed alongside the lifeboats. The motors attached to these winches are each of 27 h.p., connected to worm gear running in an oil bath. The rapidity with which the lifeboats can be manipulated, as compared by hand, must be apparent to all.

An interesting application of electric driving is in connection with the refrigerating machinery. The two gas compressors are each coupled direct to a 12-pole shunt-wound motor of 35 h.p., giving a constant torque between 40 and 110 revolutions per minute. The armature is provided with two windings, which are in series at starting, and, by turning the hand-wheel on the switchgear, the starting resistance is cut out and a variable resistance inserted in the shunt circuit to regulate the speed between 35 and 75 revolutions per minute. By transposing the armature windings from series to parallel connections without resistance, and by inserting the shunt resistance again, the speed can be increased to 110 revolutions per minute. The two brine pumps are operated by shunt-wound motors of 3½ h.p. each.

In addition to the large number of motors already enumerated, there are still a great number of other applications, but time will only permit me to refer to them briefly. Among these are the motors for driving the printing machine and the Marconi apparatus, of 5 and 3 h.p. respectively, and provision is made by having connections on deck for driving winches of 112 h.p. on the quay or in barges. In the galleys and cooking department an electric motor drives a machine capable of making bread for 3,000 people; and in the cooking ovens there are four vertical spits, driven electrically, capable of dealing with a half-ton of meat at a time; other motors are fitted to knife-cleaning machines, dish-washing machines, circular knives for cutting bacon, potato peelers, whisking machine, freezing machines for making ice-cream, and numerous electric hot plates for keeping food warm during service.

Telephone and Electric Bell System.—Telephone instruments are fitted throughout the first-class state-rooms. Having an exchange on board, passengers can converse with one another without leaving their rooms. On arrival in port the exchange is connected to the Liverpool or New York Exchange, so that passengers may be in communication with their homes or offices up till the hour of sailing or immediately on arrival. Another telephone system connects the captain and officers on watch on the bridge with the engine-rooms and crow's nest on the foremast. These consist of Graham's navy pattern loud-speaking telephones, and are used for docking and steering as well, connections being fitted on the forecastle, in the wheel-house aft, and in the steering-gear room at the stern of the ship. For the officers' use there is an intercommunication telephone service fitted, consisting of the Parsons-Sloper secret instruments, each officer being able to call up another from his own room.

In addition to the telephone system there is a large installation of electric bells with Gents' patent indicators. In every first-class state-room there is a combination fitting of electric bell push, electric light switch, connection for portable reading lamp, or curling tongs heater, and electric fans, while a number of special rooms are fitted with electric radiators. A complete installation of electric clocks is fitted on the magnetic system. In the public rooms and principal entrances and corridors there are fitted in all 48 clocks, controlled from the master clock, situated in the chart-room adjoining the bridge. There is also a complete electric fire-alarm system. A brass plate and red lamp indicate the position of the alarm push in the corridors, these being connected to indicators in the engine-room and the navigating house on the bridge deck. There is also a subsidiary fire alarm apparatus fitted near the bridge, consisting of a small cabinet into which a number of tubes are led from the various holds, a small electrically-driven fan continually exhausts the air from the tubes, and in the event of a fire it would be easily detected from which hold the smoke issued. A mercury-contact type fire alarm indicator is also fitted in the case, which, with the rising temperature, rings an alarm bell. In addition to the ordinary life buoys, there are two special buoys fitted on the bridge deck operated by Martin's electric release gear, which can be operated from various positions.

In connection with the Stone-Lloyd system of water-tight doors, an electric indicator is fitted in the navigating house which shows the position of every water-tight door in the ship. The doors are closed or opened by hydraulic power simultaneously by the officer in charge moving a handle which operates the control valve. The function of the electric indicator is to show the officer exactly what doors are open or closed. The indicator has a small lamp for each door with wires led to a contact switch at the door which, when the door is closed, completes the lamp circuit and lights the lamp.

Another important fitting on the bridge is Martin's automatic indicator for the navigating lamps. The indicator controls five lights, each light consisting of a duplicate filament lamp, one filament being lighted normally. In the event of this filament failing, the armature of a small electro-magnet which is in circuit is released, and falls against an auxiliary contact, which completes a circuit through the remaining lamp filament and through the indicator lamp corresponding to the light affected. Attention is also drawn to the occurrence by an electric horn attached to the indicator. On the officer in charge pulling a handle the horn ceases to sound, and the electro-magnet is inserted in circuit with the second filament; should this latter fail the horn again sounds, and cannot be stopped until the lamp is replaced or switched off. The several lamp circuits are controlled by the slipper switches under the indicator, and the latter is connected through a change-over switch from either the port or starboard feeder systems, thus guarding against a failure in the navigating lights.

ELECTROLYTIC CORROSION

THE Paper which Prof. W. W. Haldane Gee read before the Manchester Local Section of the Institution of Electrical Engineers last week formed a very complete study of the subject of Electrolytic Corrosion. The author reviewed several aspects of the subject in a general way, and gave the results of numerous laboratory experiments. The influence of the phenomena discussed upon engineering matters was also dealt with. The ordinary phenomena of the corrosion of an anode were first treated, and experiments tracing the anode efficiency for different current densities were described. The remarkable behaviour of some metals in becoming "passive" as anodes under certain conditions was also referred to. Anodic corrosion furnishes convenient methods for the preparation of plating solutions and insoluble oxides and compounds. The anodic stripping of tinned iron is now an established industry. Electrolysis may also be employed for the drilling of holes in hard steel plates, and efforts are being made for the application of anodic etching in photo-engraving processes. Kathode effects are also applied for certain practical purposes. When solutions of alkalies and their salts are used as electrolytes with iron kathodes, the effect of the liberated hydrogen will be to reduce any oxide films and leave the surface clean; beyond this there will be no further attack, for the alkaline solutions have no power of rusting iron. These facts may be utilised for the cleaning of iron and steel articles and for the prevention of corrosion. An electrolytic cleaning process is now coming in favour, and is to some extent replacing the use of acid pickles. Kathodic protection is the method most frequently recommended to protect underground ironwork against stray currents. It may be also used in chemical works and in manufacturing processes where metal is brought in contact with corrosive liquids. H. S. Anderson and J. W. Bennie protect the metallic screens used in mining planta against the action of acids and salts by making them kathodes against a carbon or other suitable anode. They are then able to use steel wire or punched steel screens, which are much less expensive than those made of brass or copper. To prevent the surface condenser tubes from corrosion at the Long Island power station of the Pennsylvania Railroad Company a small booster is used, the negative pole of which is connected to seven points in each condenser. J. H. Schoenberger and G. W. Frazier have designed a method for protecting the metal sheathing of ships by making it a kathode.

The action of the single galvanic couple was then dealt with, and the effect of the potential of the hydrogen at the kathode surface was discussed, and experiments made to test the actual relative rate of corrosion in the case of such couples were described. The effect of oxide coatings in accelerating corrosion was emphasised. Many examples of the disastrous effects of disregarding the principle that the more positive metal is attacked are brought under notice from time to time. Copper-bottomed ships have been the cause of legal action, as at Leghorn, where the ships and vessels lying in the harbour were found to be materially damaged by the galvanic currents set up from the copper bottoms of the yachts, electrical connections being made with the steel vessels through the ropes and hawsers which were used to make them fast to the different buoys. Damage to the ships being proved, the copper-bottomed vessels had to be removed from the harbour. The *Bancroft*, a steel practice cruiser of the U.S. Naval Academy, was abnormally corroded owing to the presence of the *Santee*, a coppered wooden vessel, some 90 ft. away—both being moored by chains to a single anchor. The commission of engineers appointed to investigate the cause of the failure of the Tay Bridge, reported that when cast iron and wrought iron were connected by rivets in many parts of the same structure, the rivets and connecting wrought-iron work had corroded by local galvanic currents. Examples of the use of couples to prevent corrosion are found in suggestions made from time to time for protecting copper surfaces from the corroding action of sea-water by providing the surface with iron strips or rods placed at intervals along it, and in electrical contact with the copper, and the mitigation of boiler corrosion by suspending in the water zinc plates in metallic connection with the boiler. Notes then follow on multiple galvanic couples, and the question whether all corrosion is not really electrolytic is entered into.

The corrosion of iron and steel in air is discussed at some length, and it is pointed out that the crusting of iron, the presence of oxygen, water, and carbon dioxide all together appears to be essential. The author considers that there can be little doubt that the carbon dioxide of the air is an important factor in causing rust. Its solution in water will provide the necessary electrolyte to give a current with the aid of the anodic and kathodic particles in the iron.

The effect of the presence of sulphur dioxide in changing the chemical nature of the corrosion is described, and the importance of the effect of structure, as revealed by the microscope, in determining the extent of corrosion is mentioned.

In speaking of lead, the Paper continues:—Lead is a very durable metal as far as atmospheric corrosion is concerned, but its liability to corrode by the action of the salts in soil, plaster, ashes, and refuse, &c., presents problems to the electrical engineer which cannot be lightly regarded. It is chiefly with the smaller sizes of lead-covered cables that the trouble is noticeable. Many examples can be given of the destructive action of the moisture of walls and the action of organic acids produced by decaying matter. Lead-covered cables are, of course, especially liable to mechanical injury, and probably this is the chief cause of faults. The whole subject has already been brought under the notice of the Institution by Atkinson and Beaver, and they conclude that "extreme care is necessary to avoid conditions which tend to produce lead faults," and they think "that the use of lead-covered cables on large networks carrying heavy currents will probably be limited in the future." Lead being electro-positive to copper and brass the contact of the two must be avoided. The same applies when the copper is tinned. The use of solder always introduces risks if a suitable electrolyte is present, hence the wisdom of the electrical instrument maker in forbidding the use of soldering fluids which contain metallic salts. On the other hand, lead is electro-negative to iron, and should not be used for fixing iron in stonework. These facts are well known, but they are disregarded only too frequently. Galvanic action has been set up between lead and tinned copper wires in the presence of moisture, causing the lead coverings to be corroded through in about two years. In this case the lead had been applied externally directly over the outer conductor.

Aluminium is largely immune from corrosive attack by the atmosphere, owing to the remarkable film of oxide which is always present on its surface. In spite of this, however, aluminium remains electro-positive to iron and copper, hence its contact with these metals must be avoided. Since it is difficult to solder aluminium, if a mechanical joint is made, it is necessary that it should be also of aluminium, otherwise a detrimental electrolytic action may be expected. There is not as yet much evidence as to the durability of aluminium transmission lines, but such experience as there is appears to indicate that it is not suitable for use near the sea coast. The oxide film being of an insulating character, aluminium wire without any other covering may be used for winding coils. The film action gives us the rectifier, the condenser, the controller, and the lightning protector.

In speaking of electrolysis produced by stray currents, the author remarked that the matter was far less serious in this country than either in the United States or Germany, owing chiefly to the limitation of drop of potential imposed by the Board of Trade. Reports of electrolytic injury to pipes come from all parts of the United States. S. Sheldon has given before the American Institute of Electrical Engineers some interesting information regarding Brooklyn, where the P.D. between the rails and hydrants, and the rails and gas mains, may be as high as 25 volts. Between the ends of Brooklyn Bridge a difference of 20 volts has been recorded. Gas services and water-service pipes have been extensively corroded. Cast-iron mains, on the other hand, have been to a large extent immune owing to their siliceous coating. It is mainly at the joints that trouble is found. Measurements made by L. T. Blake upon a line of 6 in. cast-iron water mains, which had been in service for thirteen years, in the case of a length of 339 ft. having nineteen joints gave a resistance of the joints as 88·2 per cent. of the total resistance of the pipe. Electrolytic pittings were found on many sections near the joints, but only on the positive where the stray current was shunted round the joint. The asphaltum coating of the pipe is not a sufficient protection, for under the coating—although apparently intact—pittings are found. C. E. Phelps records that 20 per cent. of the whole faults in underground cables at Baltimore during seven years were due to electrolytic action.

Very complete information as to the magnitude of the effect in Germany is contained in a report of the Deutscher Verein von Gas und Wasserfachmännern, a table from which is reproduced in the Paper, showing in the worst case (at Strassburg) a P.D. of 11·5 volts between pipe and rail. Taking H. F. Parshall's statement that, owing to the great surface of the

Digitized by Google

track and the good conductivity of the earth, about one-third of the return current passes through the earth, the question must be asked what proportion of this do neighbouring pipes carry. The experimental answer is that, as a rule, such conductors carry little or no current when the line is worked under Board of Trade conditions. The smallness of this current through cast-iron pipes has been verified by Claude. The current through the pipe is not only small, but only a small proportion of it causes electrolytic effect. Herrick shows that the corrosion of iron only reached 3·5 per cent. of the theoretical loss. The researches of the German investigators have thrown light on the reason of these small losses. The details will be found in two important papers by Haber, first in conjunction with Goldschmidt and then with Liese. Great importance is attached to whether the iron is active or passive. The change from the active to the passive state depends on the current density and the nature of the salts in the soil, the most important being the nitrates. Iron in an alkaline carbonate becomes passive, but in the presence of free carbonic acid it is attacked; on the other hand, the chlorides are always likely to produce corrosion. Generally it is found that the earth conducts electrolytically and not metallically, and its specific conductivity can be calculated from the concentration of the salt solution present in the soil. When the iron is active electrolysis is produced with just sufficient voltage to overcome the hydrogen at the kathode, but since the air of soils acts as a depolariser, this voltage will be small. Finally it is decided that a P.D. of 1 volt will not, as a rule, be harmful.

A serious aspect of electrolysis due to stray currents is the possibility of causing the solution of lead in drinking water. A case of "Plumbism due to Electrolysis" is said to have taken place in the district of the South Hants Waterworks Company. There is, however, some doubt as to whether the cause of the trouble was in reality electrolytic. Fortunately such cases are very rare, and a little consideration will show that the conditions for electrolysis to produce corrosion *within* a pipe must be altogether exceptional. If this arises it must be at the joints. If these are made in a lead pipe the resistance should be low.

Some alarmist statements have been made by Tweedy and Dudgeon on the destruction that is taking place in the overhead equipment of tramways. Through the combined effects of chemical corrosion, local action, and direct electrolysis, a very short life is predicted for overhead work. The author is unable to verify that these troubles are so bad as is represented. Of course, all exposed metal work in a town atmosphere is liable to decay, and constant inspection followed by renewals is necessary, especially in the parts of the town where chemical works are situated. Much may be done in the way of preservation by the use of protective coatings. Eternal vigilance is essential with all town metal work. As to the alleged electrolysis, if we take the leakage current across a span wire as one-thousandth of an ampere, which may be considered a limiting estimate for Manchester, with its triple insulation, then the corrosion of iron or copper will be per month less than 1 gramme, which nevertheless should cause noticeable pitting. This supposes that the whole of the current passes from bare metal to an insulating surface covered with moisture, due to very frequent rain, and that the leakage is continuous. As a rule, the leakage current will be about 1-10,000th of an ampere.

Mr. A. Watts undertook about five years ago a series of tests for the National Telephone Company at Liverpool, Dundee, Sheffield, Leeds, Bradford, and Hull, but found no evidence of sufficient potential differences due to stray currents likely to cause electrolytic trouble. The engineers of the Postal Telegraphs in London are experiencing trouble with small distribution cables, but they find that it can be guarded against by the use of petroleum jelly liberally supplied when drawing in lead-covered cables. Although the Board of Trade conditions have been fulfilled, when the cable sheaths have been cut and an ammeter inserted, readings as high as ¼ of an ampere have been noticed. Currents have also been found on the sheathing of cables on the routes of conduit system tramways with an insulated return. In a recent case, when a cable was damaged, a current of about 30 milliamperes was leaving the cable in the damaged section of the pipe. The local electric supply was alternating, and the nearest tramway (on the conduit system) was two miles distant. There were no works in the neighbourhood to account for the *direct* current which was measured. Stray currents are found circulating in the pipes and cables in every part of the Metropolis.

The question of electrical endosmose is then discussed. The effect is a common cause of faults in buried conductors, which are usually found at the negative main. On the negative side there is a constant strain on the insulation tending to drive water through the insulation to the copper. When the water gets in, electrolysis of the alkaline salts that are in solution takes place, and alkalies or alkaline metals are produced. The free metals in contact with water liberate hydrogen which, when mixed with air, forms an explosive mixture that may have caused some of the mysterious detonations that have taken place in mains. The endosmose trouble will be aggravated at high voltages and may prove an obstacle in high-pressure D.C. systems. C. H. Wordingham has noted that certain makes of rubber are porous, and water may enter and eventually destroy the whole of the rubber on the negative conductors. Some experiments are described in the Paper, showing the variation in resistance of a concrete cable duct due to this cause, and also with concrete blocks and other materials.

The rapidly increasing use of concrete for structural purposes, &c., makes the study of its electrical properties of some importance. Its specific resistance, according to the measurements that have been given in the case of pure cement, vary from 20 ohms per yard cube when wet to 1,900 when fairly dry. The addition of sand does not make much difference when the concrete is wet, but its effect when very dry is to greatly increase the specific resistance. The specific resistance thus depends on the presence of water to a very important extent. The experiments on electrical endosmose show that water may be electrically conveyed and accumulate at kathodes. The corrosion of structural steel embedded in concrete by the action of stray currents is a matter of concern in the United States. Toch has shown that steel embedded in steel can be electrolytically corroded at the anode, but if a good insulating paint be applied to the steel corrosion can be prevented. Some drastic experiments showing the effect of relative large currents on iron in concrete have been described by A. A. Knudson (Electrical Engineering, vol. I., page 564). In the absence of vagabond currents iron in properly made concrete is perfectly preserved without loss of weight, and even if used in a rusty state it will recover after some time the tint which it originally possessed. This almost incredible fact is thought to be due to the action of the cement in forming a protective coating of silicate of iron. Efforts are being made to apply electrical endosmose for the drying of peat, the extraction of sap, and in the processes of tanning.

The Metropolitan Water Board having been successful in forcing the North Metropolitan Electric Supply Company to include in their 1907 Bill a clause by which the company is liable for any electrolytic action from their alternating system has brought under debate the question whether or not alternating currents can produce corrosion. The question is one of considerable scientific interest, and is settled as far as laboratory methods are concerned. Even with a periodicity as high as 600 per second copper can be rapidly corroded in a solution of potassium cyanide. This may be due to the great rapidity of the reaction between the copper liberated during half a period, and the cyanide leading to the formation of complex substances which cannot be decomposed by the reversed current. The periodicity of commercial alternating currents being more of the order of 50, the conditions for corrosion are more favourable, but, fortunately, the salts in the earth have not so far been found to give rise to complexes. On the other hand, it is found that the efficiency of corrosion is very small, and that passivity may be produced and prevent corrosion altogether.

J. L. R. Hayden (Electrical Engineering, vol. I., page 585) has made a long series of experiments with lead and iron electrodes, using solutions of salts contained in the soil, and with the soils themselves, and he finds that the amount of corrosion rarely exceeds ½ per cent. of the amount that would be produced by the equivalent direct current.

The result of some experiments made under the author's direction may be quoted here:—Plates of commercial lead, copper, and soft iron about 5 in. × 1¾ in. × 1·12 in. thick were immersed for 144 hours in either 1 per cent. or 7 per cent. solutions of sodium sulphate, and the value of the chemical corrosion obtained. Pairs of plates, which had been each weighed, were placed in breakers containing one or other of the above solutions. The cells were arranged in series, and an alternating current of 80 ~ and 2·5 (R.M.S.) amperes was passed for 6½ hours. The plates were then withdrawn, washed, dried, and re-weighed. The results are given below:—

Metal.	Solution. Per cent.	Total corrosion in 6½ hours. Grammes.	Chemical corrosion in 6½ hours. Grammes.	Equivalent direct-current corrosion. Grammes.	Percentage of A.C. corrosion to D.C. corrosion.
Lead ...	7	0·038	0·002080	56·50	0·060
Lead ...	1	0·032	0·002030	56·50	0·053
Copper ...	7	0·030	0·000902	17·24	0·150
Iron ...	1	0·061	0·003740	10·70	0·500

Digitized by Google

In a second series of experiments a normal solution of sodium chloride was used, and the electrodes were of soft commercial lead and transformer iron. The area of each plate was 100 sq. cms. They were first allowed to corrode for 613 hours, and after being cleaned, dried, and weighed, were submitted in pairs of the same metals to alternating-current electrolysis with a virtual current of 1·5 amperes at 60 ~, the voltage across each cell being 1·5. Gas was observed on all the plates, and in the case of iron a considerable amount of rust was produced whenever a bubble adhered to the surface. The alternating current hence seemed to promote rusting. The lead plates were dipped in very dilute acetic acid before cleaning and drying. The average results are shown below :—

	Hours.	Combined corrosion.	Chemical corrosion.	Current corrosion.	A.C. Equivalent D.C. corrosion.	A.C. corrosion. D.C. corrosion.
		Grammes.	Grammes.	Grammes.		Per cent.
Lead...	15	0·127	0·00510	0·122	81·9	0·015
Iron ...	15	0·075	0·00147	0·073	22·2	0·330

One aspect of the leakage of alternating currents is whether they are capable of rectification by the valve action of certain metals such as iron, lead, and copper. This requires investigation.

An appendix by Mr. S. Butterworth contains a calculation of conductance capacity of an electrolyte due to the presence of galvanic couples of simple geometrical form, and a further appendix describes the following experiments, illustrating what takes place when the anode or the kathode are submitted to electrolysis with a small area and correspondingly high current density. A copper wire was used as an anode in a normal solution of sodium chloride, the kathode being a copper plate enclosed in a porous pot. With a current density of 0·15 amperes per sq. cm. gas commenced to be evolved, and when the current density was increased to 4·48 a loud hissing sound was produced and the anode was rapidly disintegrated. In another experiment a piece of trolley wire No. 0000 was bent in the form of a hook, so that the end could be seen on looking from above. Indiarubber tubing was slipped over the wire to insulate all but the end. The electrolyte was as before, and the kathode was of copper placed in a porous pot. With 114 volts a current density of 9·53 amperes per sq. cm. produced boiling round the electrode, and small sparks appeared at the edges. With 144 volts the current density increased to 10·6, and then a passive stage was reached. On raising the voltage to 150 the current density was only 0·42, but a bubble of gas escaped every half-minute and allowed rushes of current. A brilliant light was produced, which was still more marked at 233 volts. These experiments were made with a battery of storage cells without any external resistance, excepting that of the electrolytic cell. On changing over to the dynamo circuit a lower voltage of 200 gave a current density of 11·6. On changing back to the battery and inserting a choking coil a current density of 11·6 was obtained with 200 volts, when the amount of self-induction was adjusted above a critical point. Continuing the experiments with the dynamo, 300 volts gave current density 27·5, 500 volts of 32·8, and 600 volts of 42·4. At these higher voltages the luminous effects were brilliant, and a loud sound was produced. At 600 volts the current was 40 amperes, so that the electrolytic cell was absorbing 32 h.p. As the containing vessel was only about 1 ft. in diameter and the same deep, the experiment suggests an easy way of absorbing power, but it must be remembered that the current that is produced is a pulsating one. The electrodes were then changed to arc-lamp carbons with the high-current density at the anode; a passive state was reached at 117 volts, when light appeared. From 150 to 500 volts from the dynamo there was a Wehnelt effect. At the last pressure the current was 30 amperes, and the effect very brilliant and the noise violent. On increasing the voltage to 600 the current fell to about 1 ampere, and a slow boiling took place with the production of a yellow light. A second passive stage was thus produced. On reversing the current, the luminous effect resembled a flame arc, and 75 amperes at 400 volts was absorbed.

The final appendix is a bibliography of electrolysis due to stray currents.

DISCUSSION.

Mr. A. Watts (National Telephone Co.), referring to electrolysis due to stray currents, alluded to the experiments mentioned in the Paper which he had carried out some five to eight years ago in Liverpool, Dundee, Sheffield, Leeds, Bradford, and Hull. It would be remembered that when electric traction was first seriously thought about in this country there was somewhat of a scare as to what was going to happen to the different gas and water pipes, &c., owing mainly to alarming stories as to damage from the other side of the water. Amongst other things, the National Telephone Co. have a considerable interest in ducts, and cables underground, and it was determined to make some tests to see what was happening, and also whether the Board of Trade regulations were being carried out with any reasonable amount of care, and the speaker took a series of tests on some of the first systems opened to find out what voltages were present at different parts of the cable system. This was easily done by joining up one of the spare circuits in the cable, so that a connection from almost any point in the town could be obtained in the test-room at the exchange. The case of Sheffield was about the worst. The most important test was from a point 5·6 miles from the centre of the town, where there was a drop on the cable of 1·5 volts when practically the maximum load was on. Readings were taken between the rails and adjacent cables, and the highest readings on the outskirts of the town were about 1·25 volts with the rails positive to the cable, and in the centre of the town within a small area of about a quarter of a mile square there were readings varying from zero to 1·25 volts with the cable positive to the rail. The tests were all repeated when the tramway power station shut down to make quite sure that the readings obtained were due to the tramway currents. They had been told that there were practically no stray currents in the United Kingdom, and that they must go abroad for examples, but he had come across one case some years ago where he had found a considerable amount, viz., on the South Staffordshire tramways system, which was brought into use before the Board of Trade issued their regulations. Between the power station and Darlaston there was a drop of 13·4 volts, and from the power station to the far end of Walsall there was a drop of 16·7 volts. They had only a part of the telephone system underground in Walsall, and as they had no differences of potential in that particular case of more than 3 volts, they left it alone, but he was afraid the water people were likely to suffer before very long. There were two questions he should like to ask :—(1) The author mentioned that the Post Office engineers have obtained some readings of a quarter of an ampere by cutting a lead-covered cable. He would like some further particulars as to how the test was made and the instruments used, and the conditions. (2) With reference to the concrete tests, it struck him that some of the tests made in this case were not quite commercial tests. They were apparently made with standard sand or granite of various kinds, presumably quite clean and free from clay, &c. The ordinary man who was using concrete did not always use such good material, and it might be interesting to compare some commercial concrete with the standard material.

Mr. J. S. Cunliffe also confined his remarks to corrosion due to stray currents. Parshall in England and Claude in France have shown that although comparatively large currents flow in the earth, yet only very small currents (in the neighbourhood of one ampere) are to be found flowing in the pipes alongside the track. He had endeavoured to find the reason for this, and although his experiments were by no means complete, he could suggest a theory. He had made experiments with a view to determining the factors affecting the electrical resistance between two metallic bodies buried in the earth. The general shape of the curves obtained was about the same under all conditions within the range of the experiments. At small distances the resistance was high, whilst at larger distances it was relatively small. With the plates close together the length of the extended stream lines was disproportionately great, so that the effective area of the path was not much greater than the area of the plates themselves. With the plates far apart the percentage increase in length of the extended stream lines was not so great and the effective area of the path was enormous compared with the area of the plates. It thus appeared in the case of tramways that the resistance between the rail and the pipe which is laid beneath the surface of the same roadway was high, whilst the resistance to flow through the earth direct was small. Thus the majority of the leakage current flowed in the earth itself, only a very small percentage flowing in the pipe. Again, between adjacent lengths of a pipe system the resistance to shunting of the current round the joint must be high, and he had himself found this to be as high as 30 ohms with only $\frac{1}{4}$ in. space between the pipes. Thus, even if there is a current flowing in a pipe the resistance of the joint must be very high in order to compel that current to take the earth path. He claimed that no definite information could be obtained from electrolytic surveys. As a matter of fact, the potential difference between a pipe and the rail at any point was greater the smaller the leakage current flowing in the pipe, so that if the latter was zero, the potential difference was equal to the potential difference between that point on the rail and the point where the rail was at the potential of normal earth, *i.e.*, the potential difference between the pipe and the rail had the maximum possible value under conditions of maximum safety, whereas generally this high potential difference was accepted as a sure sign of danger. In speaking of overhead lines he referred to the ordinary insulator bolt. Under the influence of capillary attraction and to a far greater extent of electrical endosmose, water charged with atmospheric impurities was drawn between the iron bolt and the insulating material, and was forced through from the positive metal of the bolt to the negative metal of the hanger. This

Digitized by Google

impure water was a very powerful electrolyte, and electrolytic corrosion immediately commenced, and rust was formed in the practically capillary spaces, with the inevitable result that as the rust film increased in thickness the insulation was burst asunder. This applied to practically every form of traction line insulator, and could be remedied by inversion of the insulator bolt, or by reversal of the polarity of the line. This reversal of polarity had the effect also of reducing the current density where leakage currents left an underground pipe, as was shown by every possible method of computation of leakage current density, and since there was far more chance of the pipe metal becoming automatically passive at low current densities, he thought that the suggestion was worthy of consideration.

Professor A. SCHWARTZ showed a sample of an earthing clip, which was very unsuitable from the point of view of electrical corrosion, as there was tinned copper in contact with lead in contact with zinc which was on iron, again in contact with brass. With regard to the life of steel embedded in concrete, a good deal depended upon the nature of the concrete. He had made some experiments some time ago on steel embedded in coke breeze concrete, and had found that after exposure to steam and to air and water with the various strengths of cement and sand and coke breeze which are usually employed, severe corrosion followed in every case. But if the steel were coated with neat cement, then this seemed to exert a considerable protective influence upon it, and he thought in the early days of steel ships it was not an uncommon practice to coat the interior with a rendering of cement. There is one point with regard to the rusting he would like to ask the author. The presence of carbon dioxide seemed to be necessary, and they knew iron and steel had the power of occluding a considerable amount of gas. They could occlude as much as 10 or 12 times their volume of gas. On heating such a piece of iron or steel they found that carbon dioxide was given off at the lower temperatures, and he would like to ask the author whether in his opinion the CO_2 thus given off on heating, even if the surface of the material were protected by paint or some other protective medium, would be sufficient to cause corrosion. In conclusion, he referred to the action of endosmose and the production of metallic sodium and potassium, and consequent explosions in culverts; he thought, however, that this was more due to leakage of gas than liberated hydrogen, as suggested in the Paper. Cases had occurred at St. Pancras and Liverpool.

Dr. C. C. GARRARD (Messrs. Ferranti, Ltd.) criticised the method adopted by Professor Gee in some of his investigations. The true criterion in all electrolytic reactions was not the current density at the electrode, but the potential difference there. Looked at in this light, many curious electrolytic reactions became quite easy to explain. As regards the cleaning of iron articles by means of cathodic action, he had worked out a process for doing this some years ago with the object of removing the rolling scale from rolled steel sections. The steel was used for steam turbine blades, and the rolling process covered it with a hard blue scale, which had to be removed before the machining was done. He used dilute sulphuric acid with carbon anodes, and the process worked very well, the sections coming out of the bath beautifully clean and bright.

Mr. W. CRAMP called attention to the hard coating of apparently black oxide of iron produced on tramway rails, due probably to the constant sparking and rolling occurring under the car wheels. This coating was the very thing that had been sought for so long by gunmakers and others to protect the surfaces of rifles, &c. In the Birmingham Royal Small Arms factory the process used for putting on an oxide coating is kept absolutely secret, and even then the result was poor compared to that to which he referred. He should like to ask if it were not possible to make use of a similar effect to that produced by the tram wheels to design a process for putting a coating upon other articles for general commercial purposes.

Mr. REGINALD PORTER thought the author was somewhat optimistic when he said that one had to go to America to search for electrolytic troubles due to stray currents. He had, in only the last few weeks, come across three separate places in England where trouble from networks of trams was beginning to show. In two of these cases, the damaged cables were the property of municipalities only supplying alternating current, which made it all the more aggravating to the borough engineers concerned. The higher the current density, the greater the electrolytic trouble effects. In the solid system, where the lead was well insulated except at the bridges, water was apt to creep between the bridges and the bitumen, with the result that here and there the insulation at these points broke down, and if there were stray currents, owing to the insulation of the rest of the system, high current densities were produced at these points. For this reason, solid systems must be frequently and carefully earthed. The same, of course, applied to a conduit system, in which one could not rely on the joints being watertight. An engineer had told him the other day that the first time he employed metal bridges he experienced great trouble. The reason was that he had neglected to provide other earths, as he had considered the metal bridges good enough. The earthing provided by the bridges was very poor, and he had to put matters right by carefully earthing as usual. Alternating current electrolysis might be only about 1 per cent. of the electrolysis caused by an equivalent direct current. This appeared at first sight to be negligible, but with alternating currents by no amount of careful earthing can the lead sheath be made negative. So that this form of protection was useless. Alternating current effects with lighting and supply stations only were probably not worth considering, but it would be interesting to see the effect of the increase of single-phase railway systems. Conditions were aggravated in this case by the lower frequency. Mr. Hayden had proved that by superimposing a direct current 3 per cent. to 4 per cent. of the alternating current, electrolysis could be prevented, though he was under the impression that this had not yet been tried in practice.

Dr. E. ROSENBERG (British Westinghouse Co.) said that in alternating current traction, high voltages, such as 6,000 volts, were used, and therefore the current flowing through the rails was comparatively small, so that no great electrolytic action could be expected. He was very glad to find in the Paper actual figures as to the electrolytic action of alternating current. Once he had occasion to see the effect of electrolytic corrosion in the bearing of a three-phase slip-ring crane motor with a two-phase armature, the neutral point of which was connected to the shaft. When in the metallic starter, by a chance, a point of the resistance was earthed, the current flowing through the body of the crane, and through the bearing to the shaft, wore out shaft and bearing rather quickly. He was surprised that the lubricating oil did not insulate, but found that some qualities of oil on the market had so much acid that electrolysis took place to a rather unexpected degree. He saw that Professor Gee accepted the theory that the passivity of an aluminium cell was due to a film of aluminium oxide; but he had heard also of a theory that the effect was due to the accumulation of oxygen gas. With regard to the question of stray currents in Germany, the rules of the German Institution of Electrical Engineers had not been accepted by the Societies of Gas and Water Experts, but both societies had now formed a committee to investigate the matter by experiments and researches before new rules were issued.

Professor GEE in reply said that with respect to the remarks about commercial concrete, he had started with commercial concrete, and obtained such inconsistent results that he thought it would be wiser to use standard materials. The subject in course of investigation really was the resistances of porous materials, especially in connection with electrical endosmose. One point where he found difficulty was the surface drying. This might be very rapid, causing the resistance of the whole block to appear to be extremely high, whereas the inside was wet and of low resistance. He would like to consider further about the rusting of iron due to the occluded carbon dioxide. One must remember that the carbon dioxide was probably in a dry condition. Moisture must be present to form an electrolyte. With regard to current density, Haber and Goldschmidt stated definitely that the production of passivity was a matter of current density rather than of voltage. The oxide film that Mr. Cramp has noticed seemed to be well worthy of investigation, and the action of electric heating and pressure in producing oxides may be important. One speaker said that we were perhaps too optimistic about corrosion in this country. Certainly the rapidly increasing use of electricity in lighting and traction systems in which both direct and alternating currents were used might give us trouble in the immediate future, and it might be necessary to make some modifications in the Board of Trade Regulations. With reference to alternating currents, experiments showed that it was very probable that alternating current might become rectified in the earth.

Indian Telegraph Service.—About six months ago Mr. John Newlands, Deputy Controller of the Central Telegraph Office, London, was sent out to India for the purpose of reorganising the Indian telegraph system. The employees contend that the reforms which Mr. Newlands has introduced are utterly unsuitable to Far Eastern conditions, and the attitude taken up by the telegraph operators has resulted in a complete disorganisation of the telegraph service. It is stated that 2,000 telegrams are held up at Rangoon, and cables from Europe *via* Teheran are seriously delayed from Karachi onwards.

Water Power in Japan.—A report on the possibilities of development of electrical power in Japan appears in a recent American Consular Report. Several sites in the Fiyiyama district have been surveyed, and other sources of power are near Nikko, where Lake Chuzens would form a large reservoir. In the Lake Inœwashiro district some four miles of tunnel would render upward of 50,000 h.p. available. In all, some 300,000 h.p. would be available. All these power sites are located within reasonable distances of Tokyo, the minimum distance being 80 miles, and the maximum 150 miles. It is estimated that the present requirements of Tokyo represent 48,000 h.p., and that plants needing an additional 20,000 h.p. are in process of construction. These figures do not include the electric railway from Tokyo to Yokohama, or the elevated railway which is being constructed by the Government in Tokyo.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

THAT platinum is more or less attacked by hydrochloric acid when it is made the anode in a solution of the acid is well known, but one would hardly have expected the solubility to be sufficient for the preparation of chloroplatinic acid from platinum scrap. H. C. P. Weber has, however, employed this method for obtaining the fine chloroplatinic acid (*Bulletin Bureau of Standards*, U.S.A., 1908, **4**, 365). The platinum scrap is first dissolved in aqua regia in the ordinary way, and the platinum solution so obtained reduced by means of an alkali formate or with zinc, but preferably with the former. The precipitated platinum, which is in a state of very fine division, is then washed with dilute hydrochloric acid to remove any iron. After this it is placed in the electrolysing cell, which consists of a glass tube 35 cm. long and 4 cm. in diameter. The bottom of the tube has a narrow siphon, 4 mm. in bore, sealed into it. The wide tube forms the anode compartment, and in this platinum is placed, sinking, of course, to the bottom; near to the bottom of the tube a piece of platinum wire is sealed through and comes in contact with the platinum black, and is connected with the positive side of the electric supply. The electrolyte is concentrated hydrochloric acid, as also is the cathode solution.

The cathode is of platinum, and is enclosed in a porous cell placed in the anode solution. The whole apparatus is placed in a beaker, through which cold water is circulated in order to keep it cool. A current of from 8 to 10 amperes is employed. In one experiment, which was run for 4½ hours, 64 grams of platinum were dissolved. If the height of the hydrochloric acid in the cell is properly adjusted, the heavy chloroplatinic acid siphons over as it is formed, and falls out drop by drop into a receptacle placed to catch it. The solution can then be concentrated to any desired strength, chlorine gas at the same time being passed through it to oxidise any platinous compounds which may have been formed.

The manufacture of carbon disulphide in the electric furnace has been carried out for some years now by the Pittsburg Reduction Company, who use the process of E. R. Taylor. In the *Journal* of the Franklin Institute, 1908, **165**, 141, Mr. Taylor contributes an interesting paper upon the subject. The original furnace used had a diameter of 1·2 metres, and was 7 metres high; this was found not to be sufficiently large, as it became very much overheated. It has now been found that by considerably increasing the diameter of the furnace very much better results can be obtained. The present plant had a capacity production of 14,000 lb. of carbon disulphide per 24 hours, but it is now capable of producing another 25,000 lb. in the same time. The electro-thermic process for the manufacture of carbon disulphide appears the most economical and satisfactory, but very large installations are not likely to be fitted up, because of the limited use of the finished product.

Volume XII. of the *Transactions of the American Electrochemical Society* is just to hand, and well maintains the traditions of the Society for interesting publications. The volume consists of 474 pages, which, considering that the *Transactions* are published twice in the year, says a good deal for the vitality of the Society. There is a half-tone frontispiece to the volume, which is printed with "monox ink." Monox or silicon monoxide, it will be remembered, has been recently described in these notes, and is one of the most recent triumphs of electro-chemistry (Electrical Engineering, Vol. II., 382, 878). The majority of the papers in the volume have already been noticed, but we might draw attention to the paper by O. W. Brown and R. R. Sayers on "The Treatment of Storage Battery Elements before putting them out of Commission." Before transport, storage battery plates of stationary cells are usually dried, but drying the elements, unless carefully carried out, may lead to considerable loss of efficiency and decrease in the life of the battery. The authors have made a series of investigations, in which different methods have been employed for drying the plates. The capacity of the plates was first carefully tested, they were then dried, and again set up and the capacity re-tested. In some cases formalin was added to the water in which the plates were washed; this, however, is not to be recommended, as it makes the plates difficult to dry, and the formalin adheres in a very tenacious manner to the material of the plates. Negative plates should always be freed from acid before being dried, otherwise they are apt to crack and sulphate, but it does not seem to do so much harm to positives. It seems best always to thoroughly wash for 12 to 24 hours in distilled water, and then to air dry. The addition of other substances to the wash water would appear to be always disadvantageous.

There is also an interesting paper by G. Gin upon "The Electro-metallurgy of the Rare Metals." This is a long paper of 63 pages, and deals with the metals molybdenum, tungsten, uranium, and vanadium; but the principal part of the paper is devoted to the first-named. The paper is divided into three parts: (1) the concentration and purification of the ores; (2) treatment of the concentrates for the extraction of the metals; (3) the refining of the metals. In this paper is found a very useful description of the various ores of molybdenum, with their properties and distribution. The methods of separating these ores from various other minerals and gangue with which they are mixed are then described. First there is the sieving, then the electrostatic process, the apparatus of Prof. Blake, of Kansas, being described, the principle of which is as follows.

If a solid particle is close to a body which possesses an electric charge, it tends by induction or contact to acquire the potential of this body. During charging the particle is attracted to the electrified body, and when it has attained the same potential it is repelled. The phenomenon is that of the pith ball of Coulomb. This repulsion, however, is exerted at the end of a variable time, which depends upon the capacity of the particle. A powdered mixture brought into contact with an electrified body will possess a particular time factor for each of its particles, which will determine the length of its adherence to the charged surface. For good conductors this time factor is practically zero, but for dielectrics may even reach several days. This being so, one sees that if a fine layer of the powder glides down an inclined metallic surface which has an electrostatic charge, the particles will fall off in certain zones, characteristic of each of the minerals of the ore, owing to their being electrified and repelled in the order of their electrical conductivity and capacity.

Practically the process is worked as follows:—The pulverised mineral is fed in a thin layer by the shakers on to two metallic cylinders, which form the repelling poles and are continually rotated. They are charged by a 350,000-volt current, generated by Wagner's system. By means of a brush the cylinders are continually cleared from the adhering particles. The conducting particles are by this means thrown into a central receiver from which they are removed by a screw conveyor, while the non-conducting particles fall into lateral funnels. With this Blake electro-static separator separation up to 60 per cent. of molybdenite may be made from ores containing only 3 per cent. in the first place. The separator will treat from 10 to 15 tons of ore per day, and requires 3 h.p. The concentration by oil flotation (Elmores process) is also mentioned. Chemical methods of purification are then described, and the processes for manufacturing various molybdenum compounds. Finally, a description of the electric furnace for producing molybdenum is given. The furnace, as he states, differs very little from those at present used for the manufacture of aluminium. Cast molybdenum is made in a furnace similar to a carbide furnace. Finally, the induction furnace method is described. This contribution by Gin is of great interest, and for it he was awarded the Frenzel Prize by the Council of the American Electro-chemical Society.

By a happy arrangement, the members of the Faraday Society receive the *Transactions* of the American Electro-chemical Society, and their American confrères receive the Faraday *Transactions*.

The bi-annual meeting of the American Electro-chemical Society takes place at Albany, N.Y., on April 30th. The titles of the following papers have already been announced:—"Corrosion of Iron from the Electro-chemical Standpoint," C. F. Burgess; "The Electro-chemistry of Light," W. T. Bancroft; "Conduction in Electrolytes," L. Kahlen; "Copper Anodes in Chloride Solutions," P. Dushman; "The Potential of the Nickel Electrode," E. P. Schoch; "Power for Electro-chemical Industries," J. Meyer; and "Industrial Applications of Aluminium," J. Meyer.

British and American

The Helmholtz and Nernst Formulæ for the E.M.F. of a Voltaic Cell.—The well-known Helmholtz equation for the electromotive force of a cell is

$$E = \frac{H}{nF} + T\frac{dE}{dT}$$

where H is the heat of reaction or of dilution, expressed in joules, n is the valence of the cation, and F is the number of coulombs transported by a gram-equivalent of the cation. It is now fully established that the second term arises from the electromotive forces existing at the several thermo-junctions in the cell. Nernst's equation for the E.M.F. of a concentration cell, that is, a cell in which the two electrolytes are solutions of different concentration of the same salt, is

$$E = \frac{R}{nF} T \log \frac{c_2}{c_1}$$

where c_1 and c_2 are the concentrations. In the *Physical Review* of March, H. S. Carhart shows that the Nernst equation is deducible by the integration of the second term of the Helm-

Digitized by Google

holtz equation applied to a concentration cell. The Nernst equation is therefore an expression for only that part of the E.M.F. of a concentration cell which is due to electrolytic thermo-electric force. It gives the correct value for the E.M.F. of such a cell only for infinite dilution, or when the heat of dilution is negligible. The author and F. J. Mellencamp have made a series of measurements on concentration cells, made with electrolytes where heats of dilution are known. These measurements constitute an excellent proof of the Helmholtz equation. The agreement between the calculated and observed E.M.F.'s is very close. The mode of calculation can be briefly indicated here. Suppose a cell made up with two solutions, one $ZnSO_4 \cdot 50H_2O$, and the other $ZnSO_4 \cdot 400H_2O$. The act of dilution of the former to the concentration of the latter generates 82 calories. Of course, in the cell, what actually happens is that for every gram-equivalent of metal which passes from the zinc anode into the more dilute electrolyte solution, a gram-equivalent is deposited on the kathode from the more concentrated electrolyte. As the latter operation absorbs less energy than is derived from the former, the surplus energy appears in the electrical form. In the case of the sulphates of zinc and of cadmium, the experiments showed that the E.M.F. due to heat of dilution ranges from 7 to 78 per cent. of the whole E.M.F. of the cell.

A New Magneto-Mechanical Effect.—In the same journal (*Physical Review*, March), O. W. Richardson explains his view that the angular momentum of the atoms of a para-magnetic material ought to be perceptible experimentally. It is widely believed that the resultant magnetic fields which the atoms of magnetic substances possess arises from the motion of their constituent electrons in closed orbits. In a mass of matter which is distant from any magnetic field and unmagnetised, the planes of the electronic orbits may be assumed to be facing all ways, and their summed angular momentum about any axis is zero. If a magnetic field be imposed on the specimen, some of these orbits turn, in a greater or less degree, so as to face along the field. Thus the component of angular momentum of the electrons in their orbit, along the axis of the magnetic field, changes from zero to a finite magnitude. Consider a long, thin cylindrical bar of iron suspended by a fibre passing through its axis of figure so that it is capable of vibrating about a vertical axis. When the bar is not magnetised its constituent electrons will not possess any resultant angular momentum about any axis. Now apply suddenly a vertical magnetic field. The movable orbits will set so as to leave a balance in favour of the plane perpendicular to the direction of the field. This angular momentum acquired by the revolving electrons must be balanced by an equal reaction somewhere. This might be a reaction of electro-magnetic nature on the magnetising system; but the other—and, in the author's eyes—more reasonable possibility is that the expected reaction from the electronic orbit will be effective on the rest of the atom, that is, on the part which is not revolving. In this case the reaction would be made evident by a twisting of the suspended system as a whole. The author computes that the ratio between the resultant angular momentum per unit volume and the intensity of magnetisation is the same for all substances, and is equal to twice the inverse of the ratio e/m for the negative electrons; and, also, that the torsional effect should be easily measurable experimentally. So far as his experiments have gone, there has been no observable effect, but this the author attributes to the difficulty of eliminating disturbing circumstances.

Electric Discharges through Gases.—At the Royal Institution on Saturday last Prof. J. J. Thomson delivered the fifth of the course of lectures on this subject. The lecturer first showed a series of curves showing the relation between spark-length, voltage, and gas-pressure. For a constant spark-length there was a critical pressure at which the spark passed easiest; below this pressure the necessary voltage increased rapidly; above this pressure the voltage depended on the quantity of gas through which the spark must pass—or, in other words, with constant voltage the product of pressure and spark-length must remain constant (Paschen's law). For spark-lengths comparable with the wave-length of sodium light, the voltage was proportional to the spark-length, and was equal to about 1,000,000 volts per centimetre. It had been found that for spark-lengths up to three or four wave-lengths the voltage was independent of the gas used, but above this the gas used made a difference. For instance, the voltage for a spark-length of five wave-lengths was higher for carbon dioxide than for hydrogen. For spark-lengths under six wave-lengths, the voltages were different for different metal electrodes, but above this length the voltage was the same for all electrodes. For solid and liquid dielectrics, the sparking voltage was of the order of 1,000,000 volts per centimetre, as was the case with the above short lengths in a gas. In these cases there could be no ionisation by collision, but the charged particles for carrying the current must be dragged out of the electrode by the intense field. Returning to the question of the discharge through gases at low pressures, Prof. Thomson showed how the chief fall of potential took place near the cathode. If a series of metal discs were interposed between the cathode and anode, the flow of particles was interrupted, and a dark space was formed at each cathode. Each dark space meant a high resistance, and thus the discharge passed easier through the tube without the discs, although the discs were conductors. The dark space near the cathode, the negative glow, the Faraday dark space, and the striæ were due to a particular distribution of electricity in the tube, and the time interval during which this distribution took place between the application of the electric stress and the passage of the spark was quite appreciable. If the discharge was oscillatory—for instance, that from a Leyden jar, there was no time for this distribution, and the discharge was quite different. Goldstein, using this discharge, had found a new line spectrum for the alkaline metals. This form of spectrum had not been obtained with the lighter gases. Prof. Thomson then explained the principle of the vacuum-valve, in which one electrode in an exhausted bulb is enclosed in a narrow tube. This electrode cannot be the cathode, as there is no room for the formation of the dark space. Thus the discharge will only pass through the tube if the other electrode is made the cathode.

Continental

Spectrum of the Singing Arc.—The spectrum of Duddell's singing arc, which sings by resonance, is almost indistinguishable from that of the ordinary arc. But when the singing is obtained in other ways the arc spectrum may come to show all the characteristics of a simple spark spectrum. In the *Atti dei Lincei* for February 16th Michele La Rosa describes this curious phenomenon, which is best observed when a condenser is shunted across the poles of the arc, without any sensible inductance. Not only do the carbons become indistinguishable as positive and negative, but the spectrum breaks up into numerous lines, which are identical with the nitrogen, oxygen, and carbon lines observed in the spark between carbon terminals at ordinary pressures. The electrical mechanism of this change has not yet been cleared up. A gradual restoration of the arc spectrum may be brought about by lowering the capacity of the condenser. The addition of a small inductance to the shunt circuit has the same effect as a great diminution of the capacity. The lines lose their intensity in different degrees, and the carbon bands make their appearance instead. The author intends shortly to publish a more extensive study of this phenomenon.

Mechanical Equivalent of Light.—Some interesting comparisons between the ideal and the actual efficiency of electric lamps are made by C. V. Drysdale in *Bulletin* No. 274 of the French Physical Society. The efficiency of a lamp is the ratio of the light it gives to the energy supplied. This definition suffers from the well-known imperfection due to the colour of the light emitted. Strictly speaking, lights of different colours cannot be quantitatively compared. In comparing two lights of different tints, the only scientific method is to integrate the light over the different wave-lengths, comparing photometrically only the lights of the same wave-length, and adding up the amounts so found. This has to be done over the visible spectrum. The author isolated the latter by a prismatic contrivance, which is more certainly effective than the use of screens. He then measured the radiant energy by means of a bolometer, and the light in the various parts of the spectrum by means of a spectrum photometer. The results obtained with a standard incandescent lamp show that an ideal lamp giving white light would furnish 10 c.p. per watt. This would mean that all the radiant energy would appear in the form of light evenly distributed over the spectrum. For the brightest monochromatic light (540 $\mu\mu$) the amount so furnished would be 17 c.p. per watt.

Gases from Electric Sparks.—In the *Comptes Rendus* for March 23rd, M. de Broglie gives an account of some experiments in which a stream of gas was passed through a small spark gap during a spark discharge between platinum terminals. After passing through the gap, the gas was found to contain a number of gaseous ionisation products, including heavy ions, heavy neutral particles, and a kind of metallic dust. The heavy ions have a mobility of 10 microns per second in a field of 1 volt per cm., and in this respect they closely resemble the slow ions discovered by Langevin in the brush discharge. The neutral particles are easily ionised by the action of radium or X-rays, or by bubbling through water. The metallic dust is especially plentiful when sodium, thallium, or bismuth electrodes are used. The particles are ultra-microscopic, and settle down very slowly. They exhibit distinct Brownian movements. Some of them are electrified, while others are neutral. In the case of sodium, the particles quickly grow into drops when falling through moist air, owing, no doubt, to the formation of caustic soda. These gaseous products produce no cloud in the electric arc after they have been bubbled through water. But they do if the water contains metallic salts in solution. In that case they give the flame spectra of the elements dissolved.

Municipal Exhibition at Sheffield.—At the Municipal and Public Health Exhibition, which is to be held from May 1st to the 12th, a special feature will be the demonstration of methods of measuring illumination. Papers on "Illumination" will also be read at the conference in connection with the exhibition.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published April 2nd, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.
Names in brackets indicate communicators of inventions from abroad.

1907 Patents

5,508. B. G. Lamme. In alternating-current traction systems in which series commutator motors are used, the motors may be operated as generators for braking purposes. According to the present invention, the series connection is broken when it is desired to obtain a braking effect, and the field windings are excited separately, either direct from tappings on the main transformer, or indirectly through an auxiliary transformer. The armature is connected to a braking resistance or solenoids actuating a mechanical braking device. Two claims, three figures.

5,652, V. A. Fynn. Improvements in single-phase compensated series commutator motors of the type in which the main motor field is excited partially by the rotor winding. The power-factor, torque, and commutation are considerably improved by the addition of an auxiliary winding, or by the addition of auxiliary brushes, in such a manner that an auxiliary field is produced along an axis at some angle to the main motor field axis. If, for example, an auxiliary winding is placed in the axis of the compensating winding, a field will be produced at right angles in direction to the main motor field, and by suitably adjusting the phase and intensity of this auxiliary field, the conditions of a two-phase motor are approached. A better utilisation of material as well as improved starting and running are obtained. The specification describes several modifications, besides various methods of exciting the auxiliary field. Twenty-eight claims, eighteen figures.

5,853, A. Steinacker and A. Plisnier. Improvements in systems of wireless telephony with undamped electric waves. The inventors have found that a Cooper Hewitt mercury vapour lamp can be substituted with advantage for the carbon-copper arc used by Poulsen and others. The waves from the oscillating circuit are influenced by means of a strong current microphone connected as a shunt across the terminals of the inductive coil. If a capacity is inserted between the coil and earth, the microphone is connected across both coil and capacity, a better effect being obtained in the latter case. An alternative method consists in influencing the arc itself by means of a strong magnetic field the exciting winding for which is in series with the microphone. Five claims, five figures.

7,933, R. D. Archibald. A petrol-electric system for motor vehicles, in which polyphase electric transmission is used. The petrol engine is coupled direct to the external rotating field system (excited by direct-current from a battery or small generator) of the generator. The internal armature, which is also capable of rotation, is wound for generating three-phase current, and the terminals of this generating winding are connected to the terminals of another three-phase winding on the armature of the motor, which armature is also connected mechanically with the armature of the generator and rotates with it. The other member of the motor is stationary, and can be short-circuited or connected to a variable resistance. There are no brushes or slip-rings, but a switch interposed between the windings of the two armatures, and rotating with them, can open the connection or short-circuit the generating winding. The transmission can be made entirely mechanical by means of a clutch which mechanically connects together the armature and field system of the generator. The engine and field system are kept constantly running. At starting the generator acts partly as motor, but also supplies current to the motor armature. A higher speed is obtained by disconnecting the motor armature and short-circuiting the generator armature. These two speeds are both efficient running speeds, but other speeds are obtained by inserting resistances in either the motor or generator circuit. One claim, two figures.

8,764, British Thomson-Houston Co. (*General Electric Co.*). An automatic starting device for use with polyphase induction motors. The primary circuit is closed by solenoid switches, one for each direction of rotation, and the resistance in the secondary circuit is gradually cut out by another solenoid switch. The connections are so arranged that the primary circuit cannot be closed until the secondary circuit is closed through the entire resistance. No-volt releases are provided to open the primary circuit on failure of supply. Three claims, two figures.

10,440, R. C. Browne. In order to render microphone telephone transmitters more sensitive and to increase the resistance of the same without increasing the amount of granular carbon, the electrodes are, according to this invention, embedded as far apart as possible in the granular carbon so that the current traverses the material in a direction transverse to the line of pressure as applied by the vibrating diaphragm. The active material is arranged in a wide, thin layer between polished walls of some non-conducting material. The ratio of the resistance of the active material to the resistance of the line is thus considerably increased, with the result that the variations in current are greater. The electrodes are so constructed that the current will be densest in that portion of the material which is compressed the most. Six claims, six figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.
Summaries of the more important of these patents will appear in our next issue.

1907 Patents

1,373, Park & Mason. Lighting of railway vehicles.
6,649, British Thomson-Houston Co. (*General Electric Co.*). Compensated commutator machines.
6,854, Schattner & Amberion. Motor switches.
6,906, Keith & Tyson. Series commutator motors.
6,920, Fuller & Fuller. Apparatus for magneto-electric ignition for internal-combustion engines.
6,943, Davy. Electric arc lamps.
7,181, British Thomson-Houston Co. (*General Electric Co.*). Motor control for towing systems.
7,737, R. Waygood & Co. and Bone. Electric lifts.
7,742, Cowper-Coles. Electric furnaces.
8,151, Rawlings & Smith. Supports for electric lamps, shades or reflectors.
10,091A, Sutcliffe. Electric telegraph apparatus.
11,166, Highfield. Generation of high-tension direct current.
11,523, Kneen & King. Tramway conduit points.
12,172, Tatlock & Horne. Fire-alarms.
13,196, British Thomson-Houston Co. (*General Electric Co.*). Electric insulators.
13,739, British Thomson-Houston Co. (*General Electric Co.*). Electric reactances.
14,876, Noeggerath. Dynamo-electric machines.
16,366, Mayo & Houlehan. Motor starters.
16,710, Bruce, Peebles & Co. and La Cour. Dynamo-electric machines.
17,695, Stone. Space telegraphy.
17,769, Morris. Lightning conductors.
18,849, Dussek & Dussek. Laying of underground conduits and conductors.
19,244, Groom. Power storage and safety device for lifts.
19,875, Nobbs & Nobbs. Electric hot water radiator.
20,670, Drault. Mercury interruptors.
20,688, Winton. Controllers for motor vehicles.
20,932, Friedheim. Electrolytic manufacture of honeycomb radiators.
21,670, Allgemeine Elektricitäts-Ges. Motor control.
25,448, Tardieu. Microphones and telephonic receivers.
26,742, Dumaire & Moonen. Sparking-plugs.
27,400, Rawlings & Smith. Box couplings.
27,945, Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges.*). Tachometers.

1908 Patents

220, Nicholson. Selective electric signalling.
1,333, Nicholson. Telephonic receivers.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

4,637, Wagner. Electrically-driven trackless train.
4,846, Girlot. Machine for welding rings.
5,318, Swan. Incandescent lamp sockets.
5,610, Allgemeine Elektricitäts-Ges. Incandescent lamps.
5,783, Howell. Incandescent electric lamps.
5,856, Gin. Electric process of singeing textile fabrics.
5,879, Gerhardt. Automatic electrical switch.

Applications for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of April 1st.

5,104, of 1902. André Blondel seeks leave to amend the specification numbered as above, granted to La Société G. et P. de Mestral, for "Improvements in arc lamps and electrodes therefor." The proposed amendment consists in eliminating portions of the specification, including Claims 3 and 6 to 11, and Figures 10, 11, 13, and 14, and further to insert "we are aware of the Letters Patent No. 16,552 of 1898 granted to Hugo Bremer, and we make no claim to anything therein contained."

LOCAL NOTES

ACTON: *Electricity Losses.*—At a meeting of the Council last week, the following resolution was moved by Councillor Page: "That owing to the great loss in our electricity undertaking, the time has arrived when the Council shall refer to a special committee the best means of disposing the whole scheme to some private company, or at least the possibility of utilising the electric standards for gas and thereby reducing the loss of at least £1,200 or £1,300 per annum on street lighting." In moving this resolution Councillor Page alleged that the total loss in three years upon the undertaking had been about £6,000 a year, and he contended that it was impossible for any engineer to make a profit at 4d. per unit when the energy cost 5d. per unit before they sent it out. During the subsequent discussion a good deal of criticism was directed against the Council for having signed the agreement with the Metropolitan Electric Supply Co., for a supply in bulk, it being stated that the work costs were as high as 3·22d. per unit, and that sooner or later the question of generating their own energy must be considered. An amendment to the resolution that an expert be paid a fee of 100 guineas to report upon the undertaking was carried.

BECKENHAM: *Metallic Filament Lamps.*—The Electricity Committee has recommended that a circular be sent to wiring contractors in the district intimating that the Council reserves the right, without notice, to increase slightly the price of current should the general adoption of metallic filament lamps render this course necessary.

BELFAST: *Tramway Returns.*—The traffic returns for the year ended March 31st, 1908, show that the number of passengers carried was 45,465,204, and the gross receipts £190,766. For the year ended March 31st, 1907, the number of passengers carried was 43,144,418 and the receipts £178,659. The increase in the advertising and Post Office contracts was £675, and there has been, therefore, a total increase in receipts of £12,781.

Cavehill and Whitewell Tramways.—A deputation of residents in Belfast waited upon the Corporation last week with regard to the Cavehill and Whitewell tramways, complaining of the inadequate service upon the lines of the Cavehill and Whitewell Tramways Company. The deputation suggested that some arrangement might be come to between the Corporation and the Company to remedy the present position of affairs. The Lord Mayor replied that although the Corporation thought they had done everything in their power, they would see what could be done further.

BLACKROCK: *New Telephone Charges.*—The Council, as a protest against the new system of charging for telephone service, has decided to grant no facilities to the National Telephone Company so long as the new system of charges is enforced upon the public. This decision was taken as the result of a discussion upon an application by the company regarding the fixing of new poles.

BRADFORD: *Electricity Works Inspection.*—The members of the Council of the Bradford and District Chamber of Trades have been shown over the electricity works, and the opportunity was taken of holding a conference, at which several points of difference between the traders of Bradford and the Electricity Committee were discussed. The result was that the Chairman of the Electricity Committee and the City Electrical Engineer were able to promise certain concessions, and at the same time agree to bring some other points raised before the committee.

Tramway Receipts.—For the year ended March 31st, 1908, the receipts from passengers on the tramway system amounted to £232,013, an increase of £4,518 over the figures for the preceding year. The receipts from the parcels department amounted to £5,739, an increase of £725. The number of car-miles run was 5,331,009 against 5,167,261.

BURY: *The Proposed Electricity Works.*—In response to the expression of opinion at a public meeting recently that the Council should call a meeting of the ratepayers to discuss the proposed new electricity works before the Local Government Board inquiry concerning the loan, the Council has adopted the view of the General Purposes Committee that such a meeting is not necessary. It is stated, however, that the Electricity Committee is willing to receive a deputation on the question. With regard to the cost of the scheme, statements have been made that this will be £100,000, but the General Purposes Committee point out that it is proposed to expend in the first instance £62,000 and to obtain the necessary powers for another £10,000 expenditure on mains for large consumers when necessity arises.

CONWAY: *Damage to Telegraph Cable.*—The Surveyor has reported that while excavating a roadway on March 11th for the purpose of laying the curb of a new footpath on the approach to the Conway suspension bridge, a workman cut through a Post Office telegraph cable with his pick-axe. The man was under the impression that the cable was a disused one, and did not report the accident until the telegraph staff came on the scene in consequence of dislocation of the telegraph service. The Postmaster-General has written a somewhat strongly-worded letter to the Council, pointing out that on the present information it appears that the man at fault is liable to serious penalties under the Telegraph Act, 1878. The letter goes on to say that much difficulty was experienced in effecting the necessary repairs, and the cost of the work will be charged to the Council. The letter concludes with a request to the Corporation to take prompt and effective measures to ensure that there shall be no further interference with the telegraph cables by their employees.

CROYDON: *Tramway Parcels Traffic.*—The South Metropolitan Tramways & Lighting Co. has inaugurated a tramway parcel service upon their cars running between Tooting, Penge, Croydon, Wallington, Carshalton, Sutton, and Mitcham. The packages may be handed to the conductors at any of the recognised stopping places, or may be left with certain agents. The rates vary between 3d. for 7 lb. and 7d. for 56 lb.

DEVONPORT: *Dockyard Power and Lighting.*—It is stated that the change over from steam and gas for driving and lighting purposes to electricity has been completed.

DUMBARTON: *Tramways.*—The work in connection with linking up Glasgow with Dumbarton and Loch Lomond is being proceeded with rapidly, the track being now finished between Dumbarton and Renton.

DUNDEE: *New Tariff.*—The Town Council, acting on Mr. Richardson's recommendation, have now finally passed the new system of charging for power. The price to be charged in future will be on a sliding scale, with a maximum of 2½d., while power will be had at as low a figure as 0·45d. per unit, according to the number of units used. Mr. Richardson also recommended the Council to do away with the minimum charge for lighting and power altogether, and this has been done. A new feature in the scale of charges for next year will be the special price which is quoted for electric signs, and which is calculated to make this form of advertisement more popular in Dundee. Also a specially low rate is quoted for power to textile mills, &c., for which current can be obtained at ·5d. per unit for the units in excess of 50,000 per quarter, and at ·45d. per unit for those in excess of 200,000 units per quarter.

DUNFERMLINE: *The Electric Lighting Scheme.*—The result of the poll of ratepayers at Dunfermline on the question of the policy to be adopted in regard to the electric lighting Provisional Order was that out of a register of about 5,600 only 861 voted. Of these 422 votes were in favour of the Provisional Order being transferred to the Fife Electric Power Co., 323 for the erection of a generating station, and 116 in favour of taking a supply in bulk from the Power Co. A meeting of the Town Council was held on Thursday, when it was stated that a Liverpool firm of electrical engineers had offered to erect a generating station for the Council and give a guarantee against any financial loss. After a somewhat stormy discussion, a resolution that this company be asked for further particulars was carried.

EDINBURGH: *Electric Lighting Debt.*—A joint meeting of the sub-committee of the Electric Lighting and Treasurer's Committees of the Edinburgh Corporation have made a recommendation to the committees in question that in future the period for repayment of capital expenditure upon the electrical undertaking shall be 25 years.

Electric Lighting Reserve Fund.—The Treasurer's Committee recommends the investment of a further sum of £5,900 from the electric lighting reserve fund with the Gas Commissioners at 3½ per cent.

Street Lighting.—The Electric Lighting Committee have recommended that the lighting of Rose Street, a narrow thoroughfare, should be changed from incandescent gas to electricity, the lamps being carried across the street on wires suspended from the buildings on either side.

Electricity Works.—In consequence of complaints with regard to the alleged exceptional amount of Sunday labour in connection with the trimmers and lighting department, the Engineer has been instructed to minimise Sunday labour as much as possible.

FARNWORTH: *Electricity Extensions.*—The plans for the enlargement of the electricity works have been approved. These provide for an extension at the rear of the present engine room which will accommodate the engineers' offices, transforming station, and accumulator room. The new destructor works will be erected at the rear of the boiler house.

ILFORD: *Tramway Running Powers.*—A meeting has taken place between sub-committees of the tramways committees of East Ham and Ilford in regard to the question of tramway inter-communication between the two districts. As a result the Ilford Tramways Committee recommend that it is not desirable to make any alteration in the existing arrangements at present.

LEEDS: *Electricity Tariff.*—As a result of the deputation to the Corporation urging a reduction in the charges for electric power (Electrical Engineering, March 12th, page 414), the Electricity Committee recommend that a reduced scale be adopted based upon the number of units consumed per kw. of the consumers' maximum demand, as follows:—Less than 300 units per kw. per quarter, 1¾d. per unit; from 300 to 450, 1½d.:

Digitized by Google

450 to 600, 1¼d.; 600 to 720, 1⅛d.; 720 to 850, 1d.; 850 to 1,000, 0·95d.; 1,000 and upwards, 0·9d. When the units consumed are 375,000 or upwards, but less than 500,000, the charge will be 0·85d., and for a consumption per quarter of 500,000 or upwards the charge will be 0·80d. This, if adopted, will take effect on April 1st, when the cost of current for cooking purposes, &c., will be at the rate of 1½d. per unit.

Tramway Receipts.—For the year ended March 31st, 1908, the total traffic receipts amounted to £336,446 compared with £323,912 for the previous year, an increase of 3·86 per cent. The mileage run was 7,694,989 car miles, compared with 7,358,185, an increase of 4·57 per cent., whilst the number of passengers carried was 75,734,085, against 73,024,853, an increase of 3·71 per cent. The receipts per car mile work out at 10·49d., a decrease of 0·07d. compared with the figure for 1906-7. The receipts per passenger in the two years were practically the same, being 1·066d. for the last year, and 1·065d. for 1906-7.

LEYTON: *Electricity Reserve Fund.*—At the last meeting of the Urban District Council the Electric Lighting Committee, in its report, stated that for the first time in the history of the undertaking a sum of money had been set aside as a reserve fund.

Electric Lighting.—The Electric Lighting Committee has considered the memorial from residents requesting the reconsideration of the charges made for the supply of electricity, and has adjourned the matter for three months. In the meantime the memorialists have been informed that by using the latest types of lamp on the market, and which can be inspected at the Council's premises, they will be enabled to largely reduce their consumption of electricity without diminishing the lighting power obtained.

Tramways.—At the last meeting of the District Council the Tramways Committee recommended that the time having arrived, in their opinion, for reconsideration as to the charge made for the electric current used for tramway purposes, such charge should be reduced from 1¼d. per unit to 1d. per unit. This recommendation, however, was referred back.

LIVERPOOL: *Tramway Pension Scheme.*—The Liverpool Corporation Tramways Committee has approved of a scheme by which the Corporation will pay towards the benefit society in connection with the undertaking an additional 2d. per man. Contributions will also be made by the men themselves, whilst the proceeds of unclaimed property left in the cars is also to be added to the fund. The annual report of the Liverpool Corporation Tramways Benefit Society shows that the total income for the year 1907 was £3,719, and the expenditure £2,764. The amount to the credit of the Society is £7,103, of which £6,800 is invested in Liverpool Corporation bonds. The total membership of the Society is now 1,823, and during 1907 £2,010 were paid in sick allowance, the average per member in receipt of such sick allowance being £2 1s.

Tramway Revenue.—At the last meeting of the Corporation, the chairman of the Tramways Committee, Sir C. Petrie, expressed the opinion that the high-water mark in regard to tramway revenue had now been reached until further extensions were made, but he saw no probability of further extensions at the present.

LONDON: *London County Council.*—At the meeting on Tuesday, Mr. Hayes Fisher, dealing with the estimates of the tramway undertaking for the ensuing financial year, said it was calculated there would be a surplus of £110,883, and deducting £10,000 for contingencies, it was proposed that the whole of the balance of £100,883 should be transferred to the Renewals Reserve Fund. If this estimate is fulfilled, the renewals reserve fund would, at the end of the year 1908-9, amount to £316,808. With regard to the results for the year to March 31st, 1908, Mr. Hayes Fisher stated that the surplus amounted to £66,547, instead of the estimate of £41,788. It was proposed to transfer the whole of the balance, together with the sum of £5,925 brought forward, to the Renewals Reserve Fund. During the coming financial year, £254,968 would be required for repayment of capital. Out of the £8,500,000 capital borrowed for tramway purposes, £1,082,000 has been repaid. While regarding the financial position of the undertaking as satisfactory, the chairman of the Finance Committee said they could not afford to entertain any question of lower fares or extensive additions to the undertaking.

The report of Mr. T. B. Cockerton upon the accounts of the London County Council for the year to March 31st, 1907, has just been received by the Council. Dealing with the tramways accounts, mention is made of the fact that whereas the three revenue accounts, namely, the southern system, northern system, and general account have been amalgamated, separate accounts are being kept of the income and expenditure of horse and electric traction respectively. For the year in question the total receipts from electric traction amounted to £829,259, and from horse traction £585,545, equal to 12·23d. and 10·15d. respectively per car mile. Of these balances £350,839, or 5·17d. per car mile was transferred to the net revenue account in respect of electric traction, whilst upon horse traction there was a deficiency of £11,352, or 0·20d. per car mile. The amount charged against revenue account for the redemption of debt was £153,155, making a total set aside on this account, since the tramways were taken over by the Council, of £603,173, in addition to £209,573, which has been provided out of the proceeds of sales. The renewals reserve fund on March 31st, 1907, stood at £141,855, of which £85,000 is invested in 3 per cent. London County consolidated stock. Mention is made by the auditor that the sum of £55,000 transferred to the reserve fund for the year 1906–7 falls short by about £52,782 of a sum calculated on the basis of 1d. per electric car mile, which is the basis tentatively approved by the Finance Committee for arriving at the amount to be transferred yearly to renewals reserve fund out of the available surplus balance. The total capital expenditure upon the undertaking was at the date in question £2,064,700. The sum charged to tramways capital account in regard to street widening was £58,039, making a total charged at March 31st, 1907, of £190,999.

Caledonian Road and Seven Sisters Road Tramways.—The Board of Trade has intimated its consent to the use of the underground conduit system of electric traction upon these lines.

Hammersmith-Putney Tramways.—The Fulham Borough Council has intimated that it is prepared to agree to the use of the overhead trolley system on these lines.

Harrow Road-Edgware Road Tramways.—The Highways Committee of the London County Council recommends that an arrangement be made with the Metropolitan Electric Tramways, Ltd., for the Metropolitan Electric Tramways Bill, 1908, to be proceeded with, so far as regards the proposed extension of the tramways in Harrow Road to Edgware Road, subject to an agreement being entered into between the Council and the company embodying the undermentioned terms, and to such clauses being inserted in the Bill as are requisite to give effect thereto:—(i.) The company, if and when the lines are authorised, to execute the street widenings provided for in the Bill, and to construct the tramways in accordance with plans and specifications to be previously submitted to, and approved by, the Council. (ii.) The Council to purchase the tramways at the expiration of six months from the date of their completion under section 44 of the Tramways Act, 1870, on the basis of paying to the company the actual expenditure incurred by it in the construction of the tramway and the execution of the street widenings, including such sum not exceeding £4,500, as may be paid by the company to the Paddington Metropolitan Borough Council in respect of the widening of Harrow Road at Pickford's corner. (iii.) The company to enter into a further agreement, the terms of which are to be approved by the Council hereafter, embodying the terms upon which the company shall have running powers over and use the proposed extension to Edgware Road. (iv.) The tramway to be withdrawn from the Bill, unless the terms set out above are agreed to by the company.

Tramway Guide.—The Highways Committee recommend the preparation and issue of a guide to the Council's tramways, consisting of (1) alphabetical list of places of interest in London, together with, in the case of those which are accessible by tramway, an indication of the route by which they may be reached; and (2) a list of the various tramway routes with route diagrams and particulars of car service, fares, &c. The suggestion is to print an edition of 100,000 copies, which shall be placed on sale at 2d. per copy. The cost is estimated at £1,000.

New Tramway Routes.—Two new tramway routes were opened on Saturday, one starting from Brixton Station and running to Victoria Station via Stockwell Road, Vauxhall Station, and Vauxhall Bridge, and the other from Greenwich to the Obelisk at Lewisham, by way of London Road.

Bermondsey.—The Borough Electricity and Street Lighting Committee's estimate for the year ending March 31st, 1909, amounts to £10,253 for street lighting, and £5,221 for the dust destructor. The increase in connections to the mains for the year ended March 31st last was equivalent to 578kw., and the motive power connected for the year was equal to 519 h.p.

Brixton-Camberwell Tramways.—The Highways Committee recommend that the provision of trolley standards for the cars intended to run upon the Brixton Road—Camberwell Green route shall be carried out by the direct employment of labour at an expenditure not exceeding £350. The cost of equipment is estimated not to exceed £25 per car.

Finsbury: Tramway Speeds.—The Borough Council has received a communication from the Board of Trade, enclosing copy of a letter received from the L.C.C. upon the subject of the speed of electric tramcars in Goswell Road, and stating that the Board see no reason to vary the speeds to be imposed by the regulation and by-law recently issued. It has been pointed out that the rate of speed allowable is 16 miles per hour in certain parts of the road.

Lewisham: Overhead v. Underground Telegraph Lines.—The Postmaster-General has forwarded to the Borough Council a notice requiring the latter authority to give consent to the placing of telegraph poles in a number of roads. The Council's Works Committee have had reports before them in relation to proceedings on similar applications to the Woolwich Borough Council, and have come to the conclusion that the Council should adhere to their previous decisions with regard to overhead wires, that the application to the Postmaster-General be refused, and that in the event of application being made to the magistrate, all necessary steps be taken for maintaining the position taken up by the Council.

Digitized by Google

Southwark: Electricity Loans.—The Borough Council Electric Light Committee has had under consideration a letter from the Comptroller of the L.C.C. in regard to the accounts of the electric lighting undertaking. The letter points out that all loans which have been sanctioned in the past on the 42 years' system have been so sanctioned on the express condition that if any of the works, plant, or material purchased fail to be renewed during the currency of the loan, the cost of the renewals shall be provided for out of revenue, and shall not be made the subject of a further loan, inasmuch as a period of 42 years is admittedly much in excess of the usual life of plant and machinery. Provision should be made by means of a renewals or reserve fund (which the L.C.C. Finance Committee observed the Borough Council had already established, but which it suggested should be invested to create an effective reserve); that this, however, would not obviate the necessity for making provision for entire replacements, caused through ordinary wear and tear, or through obsolescence by reason of the progress of science. Further, the letter states, the Finance Committee consider the amount to be set aside for renewals should be based upon the life of the various units of plant in accordance with the periods adopted by the Council in 1906 for the repayment of loans, viz.: Land, 60 years; buildings, 50 years; mains, 30 years; plant, 20 years; house connections, 12 years; and meters, 10 years. The Borough Council Electric Light Committee point out that the District Auditor has already dealt very fully with the question at issue, and expressed concurrence in the system now obtaining, and they propose to forward a copy of his report as a reply to the L.C.C. communication.

MAIDSTONE: *Depreciation.*—The Electricity Committee, having gone carefully into the question of depreciation upon the basis of the various periods recommended by the Incorporated Municipal Electrical Association, reports that for the year ended March 31st, 1907, there should have been paid the sum of £2,710 for depreciation, whereas the amount of principal repaid was only £2,458. The Committee recommend that after March 31st, 1908, this difference should be placed to a fund called "Depreciation carried to Reserve Fund." The following percentages have been allowed for depreciation on various parts of the undertaking:—Buildings, 2½ per cent.; machinery, 5 per cent.; mains, 3 per cent.; meters, 10 per cent.; instruments, 10 per cent.; and accumulators, 10 per cent.

MIDDLESBROUGH: *Workhouse Lighting.*—The Electrical Engineer to the Corporation is to be allowed to prepare specifications for the installation at the workhouse of electric lighting.

Electric Lighting Works' Assessment.—In view of the fact that the Corporation is now taking some of its supply from the Power Company, Mr. H. M. Taylor, the Electrical Engineer, has urged the Assessment Committee to reduce the assessment upon the power-house. At present, he pointed out, the assessment is equal to 0·02d. per unit.

NOTTINGHAM: *Electric Light Charges.*—A deputation from the combined traders' associations of Nottingham waited upon the Electricity Committee of the Nottingham Corporation last week to urge a reduction of the present charges for electric supply. The resolution which led up to the deputation was passed at a meeting of the Association in January, and is as follows:—"That this meeting of the representatives of the various traders' associations in the city of Nottingham considers the present system of charging for electricity for lighting purposes most unsatisfactory, and they beg to suggest to the Electricity Committee that in future a uniform or flat rate, not exceeding 3d. per unit, be charged to all consumers, believing that this method of charging would be much more satisfactory to consumers generally."

Nottingham and Derbyshire Tramways.—A conference has been held between the General Purposes Committee and the Nottinghamshire & Derbyshire Tramways Co. with regard to the construction and working of certain tramways within the city of Nottingham, and the transfer to the Corporation of certain of the company's powers, with the result that it has been agreed that the company shall promote a Bill in Parliament with this object in view, and that the Corporation shall support it. The agreement includes the granting of running powers to the company over certain of the Corporation lines, and the tramways which it is proposed to transfer to the Corporation are those for which the company has powers to construct from Carlton, Arnold, and Beeston, joining up all the existing tramways of the Corporation. The company will also endeavour to obtain Parliamentary powers for some other lines which the Corporation will construct.

POTTERIES: *The Tramways Order.*—As the County Council has decided to oppose the Potteries and North Staffordshire Tramways (Amendment) Order, the Stoke Corporation and the other authorities concerned propose to join the County Council in presenting a petition against the Order.

RADCLIFFE: *Electricity Profit.*—The profit for the past twelve months upon the electrical undertaking amounted to between £300 and £400—equal to a penny rate.

SHIPLEY: *Electricity Charges.*—In consequence of complaints from large consumers of electricity, it has been agreed to grant special discounts to consumers for lighting purposes on accounts for over 2,000 and 3,000 units respectively.

SOUTH LANCASHIRE: *Runaway Tramcar.*—One of the cars of the South Lancashire Tramways Co. on the Bolton-Atherton route got out of control on a steep hill near Hulton Park on Thursday, and eventually left the metals and ran into a field. The driver was slightly injured.

STALYBRIDGE: *Runaway Tramcar.*—On Thursday a car belonging to the Stalybridge, Hyde, Mossley, and Dukinfield Joint Tramways Committee got out of control on a hill known as Ditcherott, near Stalybridge, and when near the bottom jumped the metals, and, breaking through a wall, fell into a brook 20 ft. below. The car was of the single-deck type, and the hill in question has a sharp turn at the bottom. Although it is only 250 yards in length, the Board of Trade regulations stipulate four compulsory stops on this incline. Nobody was seriously injured.

STOKE: *Electricity Charges.*—A recommendation by the Electricity and Destructor Committee that in future the price of electricity to consumers within the Borough be 7d. per unit for the first 60 hours per quarter of the maximum demand, and 2d. per unit afterwards, and that no customer shall be charged above an average of 5d. per unit, has been adopted. The previous charges were 7d. and 3d. respectively, without the maximum of 5d.

SWANSEA: *The Electricity Undertaking.*—The Engineer's annual report states that the number of consumers on the books is now 1,124, an increase of 166. During the year only eight consumers have discontinued taking a supply.

Free Wiring.—At the last meeting of the Electric Lighting and Tramways Committee, a discussion took place upon the question of free or assisted wiring. Col. Sinclair, the chairman, stated that he did not think it a wise policy, but a sub-committee was appointed for the purpose of thoroughly considering the matter.

TROWBRIDGE: *Electric Lighting Order.*—The Board of Trade having received an assurance from the company which holds the Trowbridge Electric Lighting Order, that negotiations are now proceeding which will lead to the undertaking being established at an early date. The question of revoking the Order has been deferred until May 31st.

TENDERS INVITED AND PROSPECTIVE BUSINESS

ACCRINGTON.—The Corporation have decided to apply to the Local Government Board for powers to borrow £7,500 for the purchase of electric cables.

CARLISLE.—A Local Government Board inquiry was held on Thursday at the Town Hall into the application of the Corporation for sanction to borrow £5,000 for cables.

BLANDFORD.—At the last meeting of the Council, owing to the unsatisfactory manner in which the gas company is carrying out its contract, a suggestion was made that there was a very good field for a company to start an electric lighting works.

DERBY.—The Tramways Committee recommend further extensions of the tramways at an estimated cost of £5,500.

DUNDEE.—Tenders are invited for the following:—(*a*) steam, exhaust, feed water, and drain piping system, with two steam-driven feed pumps and two hotwell tanks for main generating station: (*b*) equipment of circulating water pump room, including two electrically-driven vertical-spindle centrifugal pumps, in connection with the main generating station; (*c*) circulating water-pipe system (about 1,500 feet long), in connection with the main generating station; (*d*) overhead travelling cranes for main generating station and two sub-stations. Full particulars from the City Electrical Engineer, fee £3 3s., returnable, and tenders to the Town Clerk by April 27th.

ECCLES.—Extensions to the electricity plant at an estimated cost of £4,000 are estimated.

FRASERBURGH.—At a special meeting of the Council last week, a long discussion took place upon the question of acquiring the local gas company. Several of the councillors took the opportunity of urging the claims of electric light, and when a vote was taken it was found that there was not a two-thirds majority, so that the motion was declared lost.

FROME.—The Local Government Board inquiry into the application of the Corporation to borrow £10,000 for the purpose of the electricity undertaking was resumed and concluded last week.

HASLINGDON.—Tenders are invited for overhead tramway lines with tangential suspension, telephone system, and tower wagon. Particulars from the consulting engineers, Messrs. Handcock & Dykes, 1 Victoria Street, Westminster (fee, three guineas, returnable), and tenders to the Town Clerk by April 25th.

HORNSEY.—Tenders are invited for the supply of cable, feeder pillar joint boxes, &c., in connection with a new feeder cable to Muswell Hill. Forms of tender, &c., from the Borough Electrical Engineer (fee, 10s. 6d., returnable), and tenders to the Town Clerk by April 21st.

Digitized by Google

LONDON: *Poplar.*—The Electricity Committee invite tenders for the erection of a sub-station building at Millwall in brick, ferro-concrete, or corrugated iron. Full particulars from the Borough Electrical Engineer, fee 5s., not returnable, and tenders to the Town Clerk by April 29th.

Holborn.—The estimate prepared by a special committee of the Borough Council for the provision of furniture and fittings for the new Council chamber and offices, includes £550 for electric light fittings and lamps. The committee propose to obtain and consider prices.

MANCHESTER.—The Tramways Committee invite offers for a quantity of scrap-iron, steel, &c. Full particulars from Mr. J. M. McElroy, General Manager, and tenders to the Chairman of the Tramways Committee, 55 Piccadilly, Manchester, by April 14th.

MIDDLESBROUGH.—New cable is to be laid at an estimated cost of £2,000.

PENANG.—The Council of Georgetown invite tenders for the supply and delivery, f.o.b. British port, for (1) four single-deck open-type tramcars, (2) motors and electrical equipment for same. Full particulars from Messrs. Preece & Cardew, 2 Queen Anne's Gate, Westminster (fee, £1 1s., each section returnable), and tenders by April 15th.

ROTHERHAM.—Tenders are invited for a 500-kw. direct-current, steam-generating and surface-condensing plant. Particulars from the Town Clerk (fee, £2, returnable), and tenders by April 16th.

WALLASEY.—Tenders are invited for the supply of automatic overload and reverse current single-pole circuit-breakers. Particulars from the Engineer and Manager, and tenders to the Town Clerk by April 15th. The Council also invite tenders for the supply of stores during the ensuing twelve months, including switches and cut-outs, meters, cable, and junction boxes, and arc lamp carbons.

WORTHING.—A Local Government Board inquiry was held last week into the application by the Town Council to borrow £1,710 for the purposes of electric lighting. It was explained by Mr. J. Porter, the Electrical Engineer, that one of the principal items for which the loan was required was in connection with the scheme to reduce the cost of street lighting—namely, by the addition of incandescent lamps to the arc lamp standards, which would be automatically switched on at 11 p.m. The estimated saving from this was to be at £700 a year, or a rate equal to 1¼d. in the £. Another item of the loan is for the installation of condensing plant at the generating station.

TENDERS RECEIVED AND ACCEPTED

ADELAIDE.—Acting on behalf of the Electric Lighting & Traction Co., of Australia, Messrs. Kincaid, Waller, Manville & Dawson have placed an order with the Lancashire Dynamo & Motor Co. for a 1,200-ampere 180-volt motor-driven booster.

ASHTON-UNDER-LYNE.—The tender of Messrs. Parmiter, Hope & Sugden, for Ajax motor-starting switches, has been accepted for twelve months from April 1st.

BECKENHAM.—The tender of the Tudor Accumulator Co., at £1,521, has been accepted for a battery of accumulators, and that of the Lancashire Dynamo and Motor Co., at £851 10s., for a booster and switchgear.

BELFAST.—The tender of Messrs. Musgrave & Co., Ltd., has been accepted for gangways and iron railways at the Electricity Works.

BLACKBURN.—The following tenders for stores, among others, in connection with the electricity undertaking, have been accepted:—Watlington & Co. (London), red fibre sheet and presspahn sheet; India Rubber, Gutta Percha & Telegraph Works, Ltd., india-rubber solution; Siemens Bros. & Co., ozokerit tape, non-hygroscopic tape; Ruberoid Co. (London), P. and B. insulating tape and paint; Wells Oil Co., oils; British Insulated & Helsby Cables, Ltd., house service fuse-boxes; Metallic Seamless Tube Co., screwed tubes.

COLCHESTER.—The following tenders have been accepted for the supply of stores to the Electricity Department:—Fuse-boxes, Messrs. Lucy & Co., 2s. 4d. each; prepayment meter installations, Messrs. Joslins, Ltd.; joiners' work, G. Appleton; ironmongery and tools, Williams & Co.; oilmen's sundries, Joslins, Ltd.; castings, Stanford & Co.

In connection with the Tramways Department, the following tenders have been accepted:—Overhead equipment, Messrs. Watlington & Co.; standard pinions and armature coils, the British Westinghouse Electric & Manufacturing Co., Ltd.; trolley heads, sleeves, wheels, plugs, terminals, and thimbles, Messrs. W. Wood & Co.; remainder of car fittings, Messrs. Dick, Kerr & Co.; ironmongery, oils, and grease, Messrs. Joslins, Ltd.; castings, Messrs. Brackett & Co.; rubber and fibre material, Messrs. G. Angus & Co.

DERBY.—The tender of Messrs. Edgar Allen & Co., at £350, has been accepted for special work in conections with the renewal of one of the tramway junctions. Messrs. Allen's tender at £208 7s. for work in connection with the Nottingham Road carshed lay-out has also been accepted. Messrs. J. Smith & Co.'s tender, amounting to £270, for the supply of inspectors', drivers', and conductors' uniforms, &c., has been accepted.

GRAYS.—At the last meeting of the Council, tenders for cables were considered. The lowest offer was from the Union Electric Co., at £175, and the next lowest from Messrs. Callender's Cable & Construction Co., at £238. By four votes to three the Council decided to accept Messrs. Callender's tender.

LEYTON.—The Council has accepted the tender of Messrs. Bruce, Peebles & Co. for the supply of a 10-h.p. motor at £45 5s., and a starter and regulator at £8, for driving machines at the electricity station. The tender of Messrs. Headland & Headland has been accepted for carrying out for twelve months electric light repairs at schools.

LONDON: *London County Council.*—The Highways Committee recommend that a contract with Messrs. Walter Scott, Ltd., now in course of execution, for the supply and delivery of track rails and fastenings, be extended to include the supply of track rails, &c., required in connection with the reconstruction of the Queen's Road, Battersea, tramways, at an extra cost not exceeding £5,652.

The contract for the electrical equipment of the traverser at the central repair depôt has been placed with the British Westinghouse Electric & Manufacturing Co.

The tender of Messrs. F. W. Rowlands & Co., for 20,000 brake-wearing shoes has been accepted at £937 10s.

A contract has been sealed with W. R. Cunis, Ltd., for the removal of ashes from the Greenwich generating station.

Bermondsey.—The following tenders have been accepted:—J. Amos, £35 per ton, for the purchase of scrap cable; G. Gibbons & Son, for the supply of 560 zinc street lamp numbers; dynamometer to test the motors of consumers, W. G. Walker & Co., £12 10s., less 25 per cent. and 5 per cent. discount. The committee has decided to accept, subject to usual sanction, the following tenders for annual supplies:—Geipel & Lange, arc lamp carbons; Laing, Wharton & Cunnington, dynamo, booster, and motor brushes; Sutton & Co. (Overseal, Ashby-de-la-Zouch), conduits and troughing; Albion Clay Co., conduits; Sykes & Sugden, Ltd. (Huddersfield), straight through joint and disconnecting boxes and house service boxes; Campbell, MacMaster & Co., pavement frames and covers; Universal Electrical Manufacturing Co., meter boards; Silvertown Oil Storage Co., dynamo and cylinder oil; C. C. Wakefield & Co., forced lubrication chamber oil; Ferranti, Ltd., meters; Reason Manufacturing Co., Ltd., demand indicators; General Electric Co., Ltd., cut-outs; British Insulated & Helsby Cables, Ltd., concentric paper cable, lead-covered.

Hackney.—The Electric Lighting Committee has decided to accept the tender of Geipel & Co. for arc lamp carbons (Henrion make), at the following prices:—18 m/m positive, 44s. per 1,000 pieces; 13 m/m negative, 20/1d.; 16 m/m positive, 34s.; 11 m/m, 16/3d.

Islington.—After a satisfactory trial for over six months, the Borough Council Lighting Committee has decided to purchase from the Underfeed Stoker Co., Ltd., a mechanical stoker at £279.

St. Pancras.—The Electricity Committee has decided to accept the tender of Messrs. C. A. Parsons & Co. to supply and fix two new commutators to the armatures of the turbo-generator at £189 each.

Stepney.—The Electricity Committee has provisionally accepted the tender of Messrs. Thos. Crow & Sons, West Ham, at £70 (28s. per ton) for the supply of 50 tons of moulded pitch.

Wood Lane Station.—The Kensington and Notting Hill Electric Lighting Companies (Joint Works), Wood Lane, W., have ordered three Bennis and Miller-Bennett improved smokeless chain grate stokers for B. & W. water-tube boilers. This is a second repeat order.

RAWTENSTALL.—An order has been placed with the Lancashire Dynamo & Motor Co. for an automatic reversible booster.

SHEFFIELD.—Messrs. Marples, Leach & Co., inform us that they have been entrusted with the complete contract for the supply, delivery, and erection of 18 motors for driving the printing presses in the offices of the *Sheffield Daily Telegraph*. These motors are all specially designed for variable speeds where necessary, and are being wound for the Sheffield Corporation Supply, 200 volts, 50 periods, two-phase.

WILLESDEN.—The Board of Guardians have accepted the following tenders:—Messrs. Siemens Bros. & Co., supply of plant for workhouse electrical installation, £459; Messrs. Roger Dawson, wiring, fittings, &c., £727.

WIMBLEDON.—The Electric Lighting Committee has provisionally accepted the tender of Babcock & Wilcox, Ltd., at £4,710 for the supply and erection of two boilers at the electricity works, and that of the British Westinghouse Co., Ltd.,

Digitized by Google

at £2,606, to supply and erect a high-tension switchboard and gallery. For annual supplies to the electricity works, the following tenders have been provisionally accepted: Engine-room stores, Pryke & Palmer; refuse destructor tools, Jas. Harvey; cables and pilot wires, Siemens Bros. & Co., Ltd.; conduits, Albion Clay Co., Ltd., and Doulton & Co., Ltd.; joint boxes and jointing materials, W. Lucy & Co. (service boxes and house cut-outs), and Callender's Cable & Construction Co., Ltd. (for remaining items in schedule); transformers, British Westinghouse Manufacturing Co., Ltd.; ordinary meters, Ferranti, Ltd.; lubricating oils, Duckham & Co.; other oils, Blumann & Stern; lamps, carbons, and accessories, Mackey's Lamp Co. (incandescent electric lamps), Pestalozzi & Co. (arc lamp carbons); General Electric Co., Ltd. (accessories); H. G. Mayer & Co. (vulcanised india-rubber cables); "Flame" arc lamp carbons, Union Electric Co.; castings, Pryke & Palmer; firebricks and fireclay, Hall & Co. (Croydon), Ltd. (eight items).

WREXHAM.—The following tenders have been accepted for the supply of stores to the Electricity Department for the year ending March 31st, 1909:—Tools and ironmongery, Thomas Hayes; rubber cable, The General Electric Co.; ordinary service cut-outs, The British Insulated and Helsby Cable Co., Ltd.; meters, Venner & Co., and Ferranti, Ltd.; arc lamp carbons, Sloan Electrical Co.; coal, Wynnstay Colliery Co., and Barton & Co.; wood troughing, S. Rogers; boiler solution, Lee Howl & Co.

COMPANIES' MEETINGS AND REPORTS

AIRDRIE & COATBRIDGE TRAMWAYS.—At the annual meeting in London last week, Mr. F. W. Chanter, who presided, stated that the small increase of £82 in their receipts for the year 1907 over those of 1906 was almost wholly accounted for by the revision of fares, which was put into force in the summer. The working expenses showed a decrease of £70, but, principally due to repairs to the track, the repairs and maintenance account showed an increase of £420. Administration and general expenses showed an increase of £59, the whole of which increase was absorbed in rates, taxes, and insurance. For the first time the balance-sheet made provision for depreciation and renewals reserve, namely, £570 for future renewals, £225 to sinking fund, and £455 for general depreciation and expenses.

AMERICAN TELEPHONE & TELEGRAPH CO.—The annual report to December 31st last shows that the company now own a total of 3,839,000 stations, and have 8,610,592 miles of wire. Only $52,921,400 has been added to the capital expenditure during the year, as compared with $79,366,949 in 1906, owing to the general unfavourable business conditions. A sum of $36,626,667 was also spent during the year on reconstruction. The net revenue for the year was $16,269,388. A sum of $10,943,644 was paid in dividends, and $3,500,000 was added to reserve, while $1,825,744 was carried to surplus.

SIR W. G. ARMSTRONG, WHITWORTH.—The annual general meeting was held at Newcastle-on-Tyne on Wednesday last week, Sir Andrew Noble, chairman, presiding. The balance-sheet shows a net profit of £682,698, out of which £50,000 has been added to reserve fund, which now stands at £800,000, and a further £50,000 to the fire insurance account. The report and accounts were adopted. Dividends of 3s. per share on the ordinary shares, free of income tax, and 4 per cent. on the preference shares, were confirmed.

EDWARDS AIR PUMP.—At the ordinary general meeting on Thursday, the report and accounts given in our last issue were adopted. Mr. C. W. Milne, the chairman, who presided, referring to the new type of contraflo condenser, stated that these have been fitted in connection with quite a number of large turbo-generator plants, including those of the London County Council and the Glasgow, Manchester, Edinburgh, Dublin, and Sheffield Corporations. There were indications that there was going to be an enormous business done with these condensers. He also mentioned that for some time past the directors have been carrying on negotiations with a patentee of a double-acting pump on the Edwards principle, which had an increased effective displacement for the same diameter, stroke and number of revolutions per minute.

ELECTRIC LIGHTING AND TRACTION COMPANY OF AUSTRALIA.—At the annual meeting on Monday, when Mr. J. B. Braithwaite presided, the report and accounts given in our last issue were adopted. The Chairman, referring to the great drawbacks under which the company had been working for several years, owing to the want of new capital, stated that it was hoped within the next few months to be able to make arrangements which would tend to place the company upon a sound financial basis. Mr. R. P. Sellon, in seconding the motion for the adoption of the report and accounts, referred to interviews with the Premier of the Australian Commonwealth and others in regard to the growing feeling in England that the trend of politics in Australia was altogether against the employment of private capital. The directors placed great reliance upon the assurance received that this was not in any way the intention of Australian statesmen and others, and that they would do their best to have any such restrictions, if they existed, removed.

MIDLAND ELECTRIC CORPORATION FOR POWER DISTRIBUTION.—The report for the year ended December 31st, 1907, shows a loss of £10,139. The meeting is to-day.

ROSSENDALE VALLEY TRAMWAYS.—At the annual general meeting on Friday Mr. A. Love, the chairman, stated that the local authorities had given notice to purchase the company's undertaking, and that negotiations were proceeding. The number of passengers carried last year were 1,963 less than in 1906. A dividend of 5 per cent. has been declared upon the ordinary shares.

ROTHESAY TRAMWAYS.—At the annual meeting held in London last week, the report and accounts given in our last issue were adopted. The Chairman stated that in spite of the increased cost of coal there had been a decrease in running expenses.

SOUTH LONDON ELECTRIC SUPPLY.—At the annual general meeting on Tuesday the report and accounts given in our last issue were adopted. Mr. J. Atherton, who presided, referring to the satisfactory progress of the business, stated that for the March quarter of 1908 the company had sold some 100,000 units more than during the corresponding period of 1907. With regard to the dust destructor, the reduction of capital in regard to this, which had been decided upon instead of writing off the loss over a period of years, would free the company's capital account of the cost of all unproductive plant, and in addition the settlement of the dispute had freed the company entirely of litigation.

SOUTH WALES ELECTRICAL POWER DISTRIBUTION.—The sixth annual general meeting was held at Cardiff last week, Mr. W. Gascoyne Dalziel presiding. The report and accounts given in our last issue were adopted. Dealing with the unfortunate position of the company, the Chairman said that, as the shareholders had been previously told, this was due largely to the fact that the company was one of the pioneers in electrical supply for power purposes, and that many difficulties had been encountered in consequence. For instance, even after they had succeeded in inducing the large power users in the district to change over to electric power, there were frequently considerable delays, amounting at times to over a year, before the electrical plant was delivered upon the consumers' premises. In the meantime, the power company had to wait with all its plant and mains idle, which resulted in heavy losses each year, so that in 1906 the whole of its capital resources had been exhausted, and without the aid of the principal consumers it would have been impossible to continue. The inability of raising the further capital authorised by the company's Act of 1906 had led to the formation of the consumers' company for working the Treforest area and the various other arrangements in connection with the remaining generating stations. The arrangements with the Treforest Electric Consumers Co., Ltd., were now completed, and that company had taken over the working of the Treforest area as from September 1st, 1907. About £30,000 was being expended upon further plant at the Treforest station, and orders had been placed for a 3,000-kw. turbo-generator, economisers, superheaters, and other plant. Some of this had already been installed, and it was expected, at the end of another two months, that the company would be reaping the benefit of this new plant. Negotiations were still going on for the formation of a similar consumers' company to work the Cwmbran station, and it was hoped soon to bring them to a successful issue. With regard to the company's Bill sanctioning the arrangements above referred to, the Chairman mentioned that it had already passed the House of Lords (Electrical Engineering, March 26th, page 498, and April 2nd, page 533). Before concluding the Chairman expressed the directors appreciation of the friendly assistance which had been given by the large party of creditors in accepting a settlement of their claims in preference shares, as without this assistance nothing could have been done to save the company. Although these arrangements had been carried through, and were the last resource for saving the company, it would necessarily be a considerable time before the shareholders could expect any benefits from their holdings in the company, but it must be a satisfaction to them to know that the statutory powers and the two main power stations had been preserved. There were yet considerable hopes that they would attain the position anticipated for the company by its original promoters. Mr. W. Gascoyne Dalziel, Mr. W. L. Madgen, and Mr. T. Griffiths were re-elected directors.

WILLANS & ROBINSON.—At the ordinary general meeting held in London on Tuesday, Mr. Mark Robinson presiding, the report and accounts given in our last issue were adopted. The chairman stated that the fact of the profits for the half year not bearing the same relation to the volume of work done as in the past, was attributable to the unfavourable conditions of trade. As a matter of fact, the earnings of the company would allow of a greater dividend than 10 per cent. upon the

Digitized by Google

ordinary shares, but they must be prudent, and have regard to the uncertain state of the engineering trade, and for this reason the directors had deemed it wise to set aside the remainder. With regard to Queen's Ferry works, he would say little, as negotiations for a sale were being carried on.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 5s. to £60 15s. per ton (last week, £61 10s. to £62 per ton).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Notice is given of an intended dividend in the bankruptcy of Mr. U. A. Roderick, Electrical Engineer, 12 Penmaen Street, Swansea. The last day for receiving proofs is April 18th. The trustee is Mr. George David, Official Receiver's Office, 117 St. Mary's Street, Cardiff.

The creditors of the Standard Wire Co. are requested to send in particulars of their claims by May 16th. The liquidator is Mr. W. H. Armitage, Station Street Buildings, Huddersfield.

In addition to the meeting of the London creditors of Messrs. Bruce Peebles & Co. referred to in our last issue, a meeting of the Scottish creditors was also held last week in Edinburgh, when Mr. J. H. Robertson-Durham took the chair. The object of the meeting was to give the Scottish creditors the same information that had been afforded to the London creditors. At the conclusion of the meeting some local gentlemen were nominated as additional members of the creditors committee, which was appointed in London, and the full committee is now as follows: Messrs. Wishart, Scot, Cowen, Herdman, Callender, Broadhurst, Anderson, Mountain, Lamb, Gibbons and Hence.

The Electro-Medical Institute, 33 Blackfriars Street, Manchester, is to be wound up voluntarily. Mr. T. Cotton, 37 Braxennose Street, Manchester, is liquidator.

A meeting of the Medical Electro-Thermic Generator Co. will be held at the office of the liquidator, Mr. H. W. Freshwater, 7-8 Railway Approach, London Bridge, London, on Friday, May 1st, at 12.30 p.m. for the purpose of hearing an account of the winding up.

CHANGE OF ADDRESS.—We are notified that the registered office of the South Metropolitan Electric Light and Power Co. is now 183 and 185 High Street, Lewisham, S.E., where all communications should be addressed.

SIEMENS BROTHERS DYNAMO WORKS.—A new branch office has been opened at Sheffield, with Mr. E. S. Saunders in charge, in order to cope with this firm's extensive business in that district. All communications should be addressed to Foster's Buildings, 22 High Street, Sheffield.

On account of the great increase in the sales of tantalum lamps, the above firm have transferred their tantalum lamp department from White Mansion, York Street, Westminster, to their City Stores at 6 Bath Street, City Road, E.C., to which address all communications regarding tantalum lamps should be sent.

NEW PUBLICATIONS

"Principles of Direct-Current Electrical Engineering." By James R. Barr. (London: Whittaker & Co.) 10s.

"Science Abstracts": Section A, Physics; Section B, Electrical Engineering. March. (London: E. & F. N. Spon.) 1s. 6d.

"Power Gas Producers": Their Design and Application. By Phillip W. Robson. (London: Edward Arnold.) 10s. 6d.

Piccadilly "Tube" Capital.—By the Great Northern and Strand Railway Act of 1902, the Great Northern and Strand Railway Company, which had been incorporated in 1899 with a capital of £2,400,000, was amalgamated with the Brompton and Piccadilly Circus Railway Company, which had been incorporated in 1897. By the Brompton Bill, which received Royal Assent after the passing of the above Act, the name of the company was altered to "The Great Northern, Piccadilly and Brompton Railway Company." It was claimed by the Attorney-General that this company had made no statement of the increase of nominal share capital due to the capital of £2,400,000 authorised to be issued by the Great Northern and Strand Railway Company, with which the company had amalgamated, and that the company was therefore liable to pay the penalties incurred by the failure to deliver the statement required by section 113 of the Stamp Act, 1891. Mr. Justice Walton held that no new power had been granted to the amalgamated companies, and that as duty had already been paid on the powers granted to both companies, no further duty was payable. The Court of Appeal held that the nominal share capital of the company had been increased, and that it was liable to pay the penalties incurred. In the House of Lords on Friday last the company appealed against this latter decision, but the Lord Chancellor dismissed the appeal, stating that the capital of the company had evidently been increased, and that it was therefore liable to pay the penalties.

PARLIAMENTARY INTELLIGENCE

BLACKBURN CORPORATION BILL.—This Bill was before the Police and Sanitary Committee of the House of Commons last week, and was reported for third reading. Part III. of the Bill authorises the borrowing of £9,000 for new tramways, repayable in 20 years, and includes the power to purchase the Blackburn, Whalley, and Padiham Light Railway, which, when purchased, is to form part of the Corporation's tramway undertaking.

DUNDALK URBAN DISTRICT COUNCIL BILL.—This Bill was before the Unopposed Committee of the House of Commons on Thursday, and was ordered to be reported for third reading. The Bill enables the erection of a generating station for electric lighting purposes, and an amendment of the Council's borrowing powers for this purpose.

LONDON ELECTRIC POWER BILLS.—The names of a Committee of the House of Lords to consider the London Electric Power Bills are given on page 542.

NEW COMMITTEES.—A Committee of the House of Lords consisting of the following will commence the consideration of a group of Bills on May 12th, including the Great Northern, Piccadilly & Brompton Railway, the Metropolitan District Railway, and Stockport Corporation: The Marquis of Anglesey, Earl Hardwick, Lord Dunboyne, Lord Seaton, and Lord Newton (chairman).

Another committee, consisting of the following, will commence the consideration of a group of Bills on Tuesday, May 12th, including the Bristol Tramways and Keighley Corporation: Earl Carnwath, Earl Albemarle, Earl Liverpool, Viscount Hill, with Lord Ludlow as chairman.

THE NEW TELEPHONE CHARGES.—The reply of the Postmaster-General in the House of Commons last week on the subject of the new telephone charges is given in full on another page.

PROGRESS OF ELECTRICAL BILLS.—The Stockport Corporation Bill was read a second time in the House of Lords on Wednesday last week. The second reading of the West London, Barnes & Richmond Tramways Bill has been put off until May 6th. The Finchley Urban District Council Bill was read a first time in the House of Lords last week. In the House of Commons, on Monday, the London County Council (Tramways and Improvements) Bill was read a second time.

TELEGRAPH AND TELEPHONE ACCOUNTS.—In the House of Commons on Wednesday last week Mr. Harold Cox asked whether the Postmaster-General had yet completed his examination of the accounts of the Post Office telegraph and telephone departments, with a view to presenting them in a form which would show the net annual profit or less after allowing for depreciation of plant, interest upon loans, and compound interest upon payments made out of the exchequer to meet capital expenditure or loss in previous years. Mr. Sidney Buxton, in reply, reminded Mr. Cox that last autumn he appointed a committee to consider the question referred to, consisting of Mr. C. A. King, the Comptroller and Accountant-General of the Post Office, Mr. Blain, Assistant Secretary of the Treasury, and Mr. Bromley, Accountant-General of the Board of Education. The preliminary report had been received from the committee, and in the estimates for 1908-9 the two accounts had been separated. The question of preparing the accounts in order to show profit or loss on each service was now receiving the consideration of the committee.

The Gerrard Telephone Exchange.—A party of press representatives were invited to inspect the new Gerrard telephone exchange last Tuesday and general approval was expressed with the arrangements. We published a detailed description of this exchange in our issue of October 31st last, shortly after it was taken into operation. It will be remembered that it is on the standard central battery system. A feature of the switchboard arrangement is that, whilst the subscribers' lines are multipled over every six panels of the junction sections of the switchboard, they are only multipled over every nine panels of the subscribers' section. The switchboard is made up of eight-panel sections, each equipped for three operators' positions. Four-party line ringing keys are used on the subscribers' positions. A plugging up circuit of new design is another feature of the exchange. In the apparatus room the cables are brought to the vertical side of the main frame, on which side are the fuses, lightning arresters, and heat-coils.

Wireless Telegraphy.—A scheme for the signalling of Greenwich time at noon and midnight to all ships fitted with wireless apparatus was proposed at the Academy of Sciences, Paris, last week. The Eiffel Tower station at a height of 900 ft., or better, a station on the highest point of Teneriffe, was suggested as a suitable centre for transmission. A special committee has been appointed to consider the scheme. With a view of establishing communication between St. Petersburg and Vladivostock, a station is being erected by the Russian military authorities near Zlatoust, in the Government of Ufa. The place selected is the highest point of the Ural range, and another station will be erected at some point in the Altai mountain chain.

Digitized by Google

MISCELLANEOUS CITY NOTES

ANGLO-AMERICAN TELEGRAPH CO.—After placing £5,000 to the credit of the renewal fund, the directors recommend an interim dividend for the quarter ending March 31st, 1908, of 15s. per cent. on the ordinary shares, and £1 10s. per cent. on the preferred stock less income tax.

BRUSH ELECTRICAL ENGINEERING CO.—In the Chancery Division of the High Court on Saturday, on the application of Mr. Thompson, Mr. Justice Neville made an order sanctioning the reduction of the capital of the Brush Electrical Engineering Co., Ltd., by £170,484, in respect of loss of assets in freehold and leasehold factories, patents, and goodwill, shares and debentures, held in other companies.

CUBA SUBMARINE TELEGRAPH CO.—A dividend of 6 per cent. per annum free of tax for the half-year to December 30th, 1907, is recommended.

GREAT NORTHERN TELEGRAPH CO.—Although the company's receipts for last year have decreased by about £22,000, compared with those of the previous year, the board of directors intend to propose to the general meeting to distribute the same dividend and bonus as in 1906, viz., 20 per cent. (inclusive of 5 per cent. already paid), and to carry the usual amounts to the reserve and pension funds, viz., £55,555 and £8,333 respectively, whilst the dividend equalisation fund will be increased only by the interest on the same for the year.

OLDHAM AND SADDLEWORTH DISTRICT TRAMWAYS CO.—The *Manchester Courier* states that this company will shortly issue 50,000 six per cent. £1 cumulative preference shares, the whole of the 4 per cent. debenture stock having already been subscribed. The company has been incorporated for the purpose of acquiring Parliamentary powers of the Oldham and Saddleworth District Tramways Co., dated 1905, which will form a continuous route between Oldham, Saddleworth, Springhead, Mossley, and Manchester. A supply of electrical energy will be given by the Stalybridge, Hyde, Mossley, and Dukinfield Joint Tramways Board on a sliding scale varying from 1½d. to 1d. per unit. The consulting engineers to the scheme are Sir Douglas Fox and Partners.

ORIENTAL TELEPHONE AND ELECTRIC CO.—The directors recommend a final dividend of 5 per cent. on the ordinary shares free of tax, making 8 per cent. for the year.

RIO DE JANEIRO LIGHT & POWER CO.—The Paris correspondent of the *Financial News* states that, contrary to the statements which have been made in London to the effect that the French portion of the Rio de Janeiro Light & Power Co.'s loan would be brought on the market under the auspices of the Banque de Paris et des Pays Bas, the issue will take place under the control of a private firm. The loan will shortly be offered simultaneously in London and Paris. The Paris firm, which is just now engaged in placing privately among its *clientèle* 6 per cent. bonds of the Rio Janeiro Light & Power Co. is Messrs. Gern & Rafzovitch. Where the Banque de Paris et des Pays Bas comes in is that it has previously granted, together with the Société Générale, an advance of 5,000,000f. on this issue of the Rio Janeiro Light & Power Co. Messrs. Gern & Rafzovitch, it appears, have taken over for cash 10,000,000f. worth of the new bonds, and have an option over another 20,000,000f. should the operation be successful. However, it is hardly likely that the French market is ready just now to absorb the bonds, in spite of their high yield.

NEW COMPANIES

ELECTROMOTOR EQUIPMENT.—This company was registered on March 24th, with a capital of £5,000 in £1 shares (4,500 preference), to carry on the business of electricians, mechanical and general engineers, workers of and dealers in electricity, motive power and light, manufacturers of electrical apparatus, &c. The subscribers are: O. Spatz, E. B. Haertel, H. G. Haertel, O. Reimers, W. J. B. Tippetts, P. W. B. Tippetts, and T. Meacock. No initial public issue. The number of directors is not to be less than three nor more than five; the first are G. Reimers, O. Spatz, and H. G. Haertel. Qualification, 100 shares.

FIFE SYNDICATE, LTD.—This company was registered in Edinburgh on March 31st, with a capital of £10,000 in £1 shares, to purchase, lease, or otherwise acquire, manage, and work any light or other railways, electric or other tramways, and electric lighting or power undertakings, and to take over the control of the statutory rights and powers under the Dunfermline and District Tramways Order Confirmation Act. The subscribers are:—W. Shearer, G. A. Nicolson, C. Brunton, J. C. Greig, A. Annie McFarlane,, F. E. Somerville, M. I. Hamilton. The first directors are not named.

Wireless Telephony.—Some experiments were carried out last week by Dr. Lee de Forest before the French naval and military authorities in Paris. Communication by wireless telephony was established between the station at the top of the Eiffel Tower and the stations at Melun (about 37 miles distant), Mont Valérien, and Villeneuve St. Georges. Experiments are to be carried out before the naval authorities in Italy and in this country.

APPOINTMENTS AND PERSONAL NOTES

The General Purposes Committee of the Accrington Corporation recommend that the salary of their Borough Engineer, Mr. W. J. Newton, be increased from £420 to £470 per annum, in view of the long and arduous services rendered in carrying out the electrification of the tramways and the additional duties and responsibilities involved in the supervision of the new tramways.

Mr. H. Bloodworth, who recently represented the Adams Manufacturing Co., and was formerly a buyer for Messrs. Edmundson's Electricity Corporation, will in future represent Messrs. Siemens Brothers Dynamo Works, Ltd. He has been attached to their London branch at 1 Abchurch Yard, Cannon Street, E.C.

In consequence of the resignation of Mr. F. Dickinson, the works superintendent at the St. Helens Electricity Works, the following alterations in the staff have been made:—Mr. R. R. Mayne, works superintendent, £3 5s. 4d. per week; Mr. J. W. Warr to be made responsible for the mains and service, in addition to his present duties as traction and motor superintendent, at a salary of £3 5s. 4d. pr week.

Mr. H. G. Thompson, of Swansea, has been appointed electrical engineer to the Neath Urban District Council at a salary of £200 per annum.

Lord Kelvin's Will.—An inventory of the estate of the late Lord Kelvin (says the *Times*) was lodged with the sheriff clerk at Kilmarnock yesterday. The will, which is holograph, is dated December 8th, 1905. There are three codicils attached to it. Lord Kelvin leaves his wife, Frances Anna, all his property real and personal, and his patent rights and goodwill in respect of inventions other than those which belong to Kelvin and James White (Limited), Glasgow. Lady Kelvin is appointed sole executrix. The personal estate consists of £45,027 8s 9d. in Scotland, £79,247 11s. 10d. in England, £4,650 in Ireland, and £32,998 11s. 2d. abroad—a total of £161,923 11s. 9d.; and heritage £7,150. The net estate heritable and movable on which duty has been paid is £155,053 15s., and the amount of estate duty paid is £10,944 13s.

The New Telephone Charges.—In the House of Commons, on Wednesday last week, Mr. Hudson asked the Postmaster-General whether he was prepared to make any statement as to the future policy of the Post Office on the subject of telephone rates, and especially in regard to the financial basis on which he proposed that the Post Office telephone system should be conducted. Mr. Sydney Buxton, in reply, said he was glad to have an opportunity of stating his views on the question of the future policy of the Post Office in regard to telephone rates. He considered that the Post Office telephone system should be conducted on a sound business basis, that is to say, that the revenue should be sufficient to provide for current expenditure of all kinds, for the maintenance and adequate renewal of plant, and for interest at 3 per cent. on capital expenditure, together with a moderate but not excessive margin of profit. In order to ascertain whether the rates were fixed at a level sufficient to satisfy these conditions, and to put the telephone service on a business footing, it was necessary that there should be a clear separation between the revenue and expenditure of the telephone service and the revenue and expenditure of other branches of the Post Office, especially the telegraphs. It was in this way alone that the telephone system could be made to stand on its own basis, unaffected by the profit and loss made on other Post Office services. The various branches of Post Office work were, in practice, frequently conducted in the same building, sometimes by means of the same plant and under the supervision of the same persons. The separation of the cost was consequently a matter of some difficulty. Last autumn, therefore, he appointed an expert committee, including the President of the Institute of Chartered Accountants, to investigate this question, and to advise as to the best method to be adopted for separating the accounts. The committee had not yet finished its work; but, as a first result of their investigation, the Estimates for 1908-9 had been presented to the House in such a manner as to separate the expenditure on telegraphs and telephones, and the telephone revenue would be shown separately. The new telephone rates must to some extent be regarded as experimental. Longer experience was required before it was possible to say what might be the permanent cost of operating a fully developed system, or to ascertain with any accuracy the life of the varying descriptions of telephone plant, having regard especially to probabilities of obsolescence, and the consequent necessity of replacing plant before it was worn out. Moreover, the conditions under which the Post Office service was conducted would be considerably modified when the system of the National Telephone Company was taken over by the Post Office at the beginning of 1912. Although it was not possible for him to pledge his successors, he should anticipate that the principles which he had stated as those which should determine the rates would be accepted by them, and the rates would doubtless be from time to time modified in accordance with those principles.

Digitized by Google

PURCHASE OF HIGHGATE HILL CABLE TRAMWAYS

In a further report by the Highways Committee of the London County Council, full details are given as to the proposal to purchase the Highgate Hill cable tramways. The tramways are of narrow gauge, are worked by cable traction, and consist of about 0·71 route mile of partly double and partly single track along Highgate Hill, situated in London and Hornsey. The total length of line expressed as single track is about 1·31 miles, of which about 0·94 is in London and 0·37 in Hornsey. The Council was in a position in 1903 to serve notice to acquire compulsorily, under section 43 of the Tramways Act, 1870, the portion of the undertaking situated in London, but decided not to exercise its powers of purchase at that time. These powers of compulsory purchase will, in the ordinary course, recur in 1910. The company has introduced a Bill into Parliament in the present session (1) to authorise the company to reconstruct its tramways for electric traction on the standard gauge, (2) to postpone the date of compulsory purchase of the lines by the local authorities, of which the Council is one, under the Tramways Act, 1870, and (3) to confer on the company running powers over portions of the Council's tramways. As stated in a former report of the Highways Committee, the company has approached the Council with a view to the transfer to the Council at an early date of their undertaking by agreement, in which event the company will not proceed further with its Bill. As the result of negotiation, the company has now expressed its willingness to withdraw its Bill and to sell its whole undertaking to the Council upon terms which, in all the circumstances, the Highways Committee feel justified in recommending the Council to accept. It is proposed that the Council shall enter into a provisional agreement to purchase not only the portion of the undertaking in London, but also the small portion in Hornsey, and that the purchase price shall be £13,000. As regards the portion of the lines in Hornsey, the Hornsey Corporation is the "local authority" under the Tramways Act for the purchase of tramways. The Hornsey Corporation will not raise any objection to the arrangements proposed, provided that it is not involved in any financial responsibility in the matter. It will be necessary for an agreement to be entered into between the Council, the Hornsey Corporation and the company, to give effect to these proposals. Such agreement will have to be submitted to Parliament in the session of 1909 for confirmation, and the agreement will be conditional upon the Council obtaining such confirmation.

The London portion of the Highgate Hill tramways meet the Council's electric tramways system (Holloway Road route) at the Archway Tavern, and, says the report, the existing travelling facilities in the districts affected would be considerably improved by working the two systems in conjunction. The Committee recommend that when the Highgate Hill tramways are purchased by the Council they should be reconstructed on the standard gauge for electric traction as soon as possible in order to utilise them as a feeder line to the existing tramways.

In a report upon this proposal, the Finance Committee states that the total ultimate expenditure on capital account in connection with the reconstruction on the conduit system of the lines, when purchased, for electric traction, is roughly estimated at £53,200, made up as follows: Purchase of undertaking, including incidental expenses, £13,500; tramway construction, £20,000; cars, £3,920; cables and ducts, £2,680; street widenings, £10,700; and car-shed and sub-station accommodation, £1,402. If the overhead system were adopted this figure would be reduced by about £6,045. The gross surplus on working is estimated at £3,042 for the first year of working. Against this must be set debt charges on the capital outlay amounting in the first year to £3,836, and provision for renewals at 1d. a car mile, amounting to £608; so that the deficiency in the first year would amount to £1,441. Debt charges would decrease by about £70 a year as the debt was paid off, and the adverse balance would thus disappear in about 20 years, provided the estimate of traffic were realised. But although the direct traffic of the line appears to be small, the Highways Committee are of opinion that the induced traffic over other parts of the Council's system would be considerable; and it may therefore be assumed that the line would prove to be self-supporting in considerably less than 20 years.

International Telegraph Convention.—The annual report for 1907 of the Bureau International des Administrations Telegraphiques, shows that the revenue estimated at 64,500 francs amounted to 62,773 francs, while the expenditure at 141,577 francs was less than the estimate by 20,958 francs. Thus a sum of 78,804 francs has to be met by the administrations adhering to the Telegraph Convention, or less by 19,231 francs than the estimated deficit. There are 48 countries adhering to the Convention, and 19 telegraph and cable companies. Fifteen other companies correspond with the Bureau direct, although they are non-adherents, while five others correspond through the medium of one of the other groups of companies.

ELECTRICITY FROM PEAT

Rejection of the Dublin & Central Ireland Power Bill

The Committee of the House of Commons, presided over by Mr. Luke White, concluded its consideration of this Bill on Wednesday last week, and declared the preamble of the Bill not approved, too late for insertion in our last issue, in which we gave full particulars of the proceedings up to Tuesday. At the conclusion of the evidence of Captain Sankey, further evidence was called as to the possibility of business being done in the area, and to the want of provision for giving cheap supply in the districts surrounding Dublin and elsewhere.

Mr. E. A. Aston, representing a firm of mechanical and electrical engineers in Dublin, compared the cost of current supplied by the Corporation, which, he said, averaged 1·45d. per unit, with the proposed supply of the company, which would average ½d. per unit. In reply to the Chairman, this witness stated that if the Dublin Corporation took the whole of their supply in bulk from the company, and were to abandon their present plant, the capital cost of which was about £120,000, this debt might be reduced to £100,000 by the sale of the plant, and the sinking fund on this would be about £6,000 a year, as against £10,000 or £12,000 a year which would be saved by taking a supply in bulk.

The general point in the cross-examination of this witness was that those parties owning generating stations, in the event of their taking a supply in bulk, would have to scrap their plant and still bear the burden of the cost of distribution.

In answer to the Chairman, the witness stated that the right to supply Dublin with the consent of the Corporation was essential to the development of the scheme.

Captain H. Riall Sankey, who was recalled, gave estimates which, he said, he had prepared on the financial prospects of the company in connection with the supply of electricity. He put this at 7·6 per cent. on the ordinary shares, irrespective of the profits on the by-products.

On behalf of the opposition Mr. Seymour Bushe, K.C., addressed the Committee for the Dublin Corporation, and described the scheme as being speculative, experimental, and crude, and mentioned that many previous schemes had been put forward for exploiting the Bog of Allen, but all had been failures. The Corporation desired to be cut out of the Bill altogether, and that was all he desired.

Sir Ralph Littler, K.C., addressed the Committee on behalf of the Pembroke Urban District Council and the Alliance and Dublin Consumers' Gas Co., dwelling upon the scarcity of evidence as regards capital.

The Chairman asked for further information on the question of finance.

Mr. Freeman admitted that it would be impossible for him to say what capital would be invested in the company until it was known in what form the Bill would be passed.

After a short consultation, the Chairman stated that the Committee were unanimously of the opinion that the preamble was not proved.

The Electrical Engineers' Ball.—We understand that this function was particularly successful this year, as regards both the number of guests attending and the financial result. At a meeting held on March 31st, the committee were enabled to vote, from the available balance for the year, a sum of £75 for the Benevolent Fund of the Institution of Electrical Engineers.

Tramway Rating.—In the Appeal Court, on Monday, the Assessment Committee of the Hendon Union appealed against a rule *nisi* granted by Mr. Justice Phillimore prohibiting the justices of Middlesex from hearing an appeal by the Metropolitan Tramways, Ltd., against their assessment by the Hendon Union whilst certain magistrates, who are members of the Middlesex County Council, were on the bench. We gave full particulars of the action in our issue for March 5th, page 371, and March 12th, page 396. The appeal came before the Lord Chief Justice, Mr. Justice Ridley, and Mr. Justice Darling, and the decision of Mr. Justice Phillimore was reversed. The Lord Chief Justice, in giving judgment, thought that the view that the justices in question would be biassed, was a far-fetched one.

Telegraph Traffic.—The cable of the French Telegraph Company between Guantanamo (Cuba) and Mole St. Nicholas (Hayti) has been repaired, the interruption having lasted from February 11th to April 1st. The land-lines between Rangoon and Calcutta via Akyab are down, and this derangement, together with the strike of operators (see note on page 562), is causing serious delay on European telegrams to and from Rangoon. The Eastern Extension Australasia and China Telegraph Company are, however, now laying a submarine cable between the Cocos-Keeling Islands and Java, and this will give an extra route to India, as by agreement with the Indian Government, messages must be sent via Aden and Cocos at normal rates, if the other route is encumbered or interrupted. This arrangement also refers to telegrams to the Far East. On the 5th instant, the route via Hanekin was restored, and on the 6th instant the via Fao route, which was interrupted between Bagdad and Bassorah, was put into working order, but subsequently ceased working again.

THE SIMPLEX TIME ELEMENT THERMAL CUT-OUT

THE accompanying illustration represents a piece of apparatus which Simplex Conduits, Ltd., have recently brought out for protecting motor-circuits and similar purposes. The appliance is actuated thermally, and is designed to have a true time element, allowing momentary rushes of current, but opening the circuit as soon as the excess of current becomes dangerous.

The device is very simple, and consists of a chamber containing a resistance above which is placed a corrugated capsule, the expansion of which causes a piston pressing directly on to it to raise and actuate the trigger of the switch. The capsule can exert a pressure of 20 to 30 lbs. without being damaged, the operation being therefore assured under any circumstances.

The apparatus, when once set, sets quicker or slower according to the magnitude of the current flowing. With normal current it absorbs only about five watts, and the heat developed in the chamber is radiated, but any overload above 10 per cent. will cause the device to act in a time inversely proportional to the overload. Any motor or arc lamp takes at starting an increased current, and especially so the alternating-current motors, and, in fact, there always is a rush of current on closing a circuit. To permit this, therefore, the fuse or magnetic cut-out have to be set so as to fuse or open the circuit with 50 per cent. up to sometimes 300 per cent. overload, the

THE "SIMPLEX" TIME ELEMENT THERMAL CUT-OUT.

direct consequence of this being that they afford very little protection. The thermal cut-out not only allows the rush of current at starting, but also prevents this or any smaller excess above the normal to flow for an undue time, and thus affords protection. If desired, an arrangement can be added so that an alarm is given as soon as the piston begins to rise, and before the cut-out opens, thus giving sufficient warning to the attendant.

Some tests of a 20-ampere cut-out have been made at the Electrical Standardising, Testing, and Training Institution. Overload currents of definite amount were passed through the cut-out, and the time taken by the cut-out to act was noted. The following table gives the results:—

Current amperes.	Overload per cent.	Time of action.
23	15	14 min. 0 sec.
25	25	4 min. 57 sec.
30	50	2 min. 0 sec.
35	75	1 min. 11 sec.
40	100	54 sec.
50	150	39 sec.

These times are stated to agree as reasonably as can be expected with the rating of the appliance, slight alterations being produced by the presence of stray currents of air. The mechanical action of the cut-out reported as quite satisfactory, the power exerted by the capsule being ample for the purpose of opening the switch. The watts taken at the switch terminals when warm were also measured and found to be 5.5.

Telegraphists' Conference.—The twenty-eighth annual conference of the Postal Telegraph Clerks' Association is being held in Glasgow this week. The business meetings commence to-day, and the annual dinner takes place on Saturday.

CATALOGUES AND PAMPHLETS RECEIVED

"CHLORIDE" ACCUMULATORS.—The latest publication of the Chloride Electrical Storage Company might be taken for a catalogue of complete steam yachts rather than accumulators, as it contains a series of most handsomely executed reproductions of photographs of steam yachts, in which the lighting is carried out by the aid of Chloride accumulators, including the King's new yacht *Victoria and Albert*, and other Royal and private vessels. Particulars are also included of the special type of cell which the company have developed for shipboard use.

ELECTRIC CLOCKS.—A pamphlet from the Standard Time Co., of 19 Queen Victoria Street, contains reprints of a number of letters in the *Times* dealing with the desirability of a standard time service, and a lecture by Mr. St. J. Winne, director of the Standard Time Co., given recently before the United Wards Club of the City of London on "The Time of a Great City," and a report of the discussion thereon, in which the advantages of electrically synchronised public clocks are pointed out.

METALLIC FILAMENT LAMPS.—A collection of leaflets from Messrs. G. M. Boddy & Co., of Newington Works, Liverpool, gives particulars of a metallic filament lamp being put on the market under the name of the "Metalik." The lamp has the usual elongated bulb and filament in several sections. The efficiency is given at 1¼ watts per c.p., and the average life as 1,000 hours. The following sizes are listed:—25 c.p., at 50 to 75 volts; 32 c.p., at 50 to 130 volts; 50 c.p., at 75 to 130 and 200 to 240 volts; and 100 c.p., at 100 to 130 and 200 to 240 volts In the latest form of lamp the filament, both in the case of high and low voltages, is so supported that the lamps may be used inclined to any angle.

POLYPHASE MOTORS.—The Union Electric Co. are issuing a very comprehensive list of polyphase motors. The motors dealt with range from ¼ to 340 h.p., and run at speeds from 1,500 r.p.m. to 375 r.p.m. for various voltages from 110 to 5,000. The types include those with squirrel-cage and wound rotors, the latter with or without brush raising gear, and the motors can be supplied as protected, enclosed ventilated, or fully enclosed machines. Several types of starters are listed.

SHADES FOR METALLIC FILAMENT LAMPS.—A circular is to hand from the Sun Electrical Co., of Charing Cross Road, illustrating some new designs of specially deep glass shades for use with tantalum and osram lamps.

SIMPLEX CONDUITS.—A complete catalogue of these conduits and accessories for use with them has been issued, written entirely in French, and with prices in francs.

SMALL TRANSFORMERS FOR METALLIC FILAMENT LAMPS.—A new list from the Union Electric Co. deals with this firm's patterns of small transformers for reducing the ordinary supply voltages to those more suitable for metallic filament lamps of moderate candle-power. These transformers were described and illustrated in ELECTRICAL ENGINEERING, March 5th, page 353. They are constructed in a great variety of ratings for various primary pressures, as usually found on supply companies' mains, and for the whole range of periodicity in use in this country. Two chief patterns are included and priced, viz., those with a single-circuit secondary and those with a multiple-circuit secondary. On the last page are given diagrams showing the method of connecting the transformers to the primary and secondary circuits, as well as details of construction and technical data.

STEAM ENGINES.—Messrs. Ruston, Proctor & Co., of Lincoln, have sent us a pamphlet giving prices of their well-known single-cylinder vertical high-speed engines, with flywheel inertia governors, in sizes ranging from 16 to 76 h.p. A blotter is being issued by the same firm embellished with illustrations of a suction-gas plant, and a horizontal cylinder gas engine of their manufacture.

STONEWARE CONDUITS.—A leaflet which has been issued by the Albion Clay Co., of 38 Victoria Street, relating to the Sykes' patent stoneware conduits with self-centring joints. It is stated that over 9,000 yards of this conduit have been laid at the Franco-British Exhibition entirely without concrete. An illustration is given of a ten-way conduit forming part of this contract in the process of being laid.

TRAMWAY ACCESSORIES.—A leaflet from Mr. F. J. Down, of 6 Crutched Friars, E.C., gives particulars of several accessories useful in tramway and railway work. A special guy anchor is included, and other articles include a lever arrangement for moving cars by hand and two forms of car ramp for replacing derailed cars on the track.

TRANSFORMERS FOR METALLIC FILAMENT LAMPS.—A new pamphlet from the Foster Arc Lamp and Engineering Co., of Wimbledon, calls attention to the advantages which can be obtained by the use, on alternating-current circuits, of small auto-transformers for enabling low voltage metallic filament lamps to be employed. Some diagrams are given showing the way in which such installations may be wired so as to obtain the full advantage of the balancer action of such transformers by dividing the installation into two or more sections from different tappings of the auto-transformer. Two examples

Digitized by Google

are worked out, showing savings of 71½ and 66 per cent. respectively by the adoption of this system of lighting, as against ordinary carbon filament lamps.

VENTILATING FANS.—The Wilson Wolf Engineering Co., of Bradford, have issued a new complete list of ventilating fans of the "Arctic" propeller type, both in the continuous-current electrically-driven type and also for belt driving. The principal improvements in these fans were referred to in Electrical Engineering, March 26th, page 480, in connection with a preliminary catalogue of the same apparatus.

A NEW ELECTRIC TEA KETTLE

THE accompanying illustration shows a cheap form of electric kettle which the British Thomson-Houston Co. have now brought out and added to the already long list of heating

New B.T.-H. Electric Tea Ketile.

appliances which we have referred to from time to time as new apparatus has been introduced. The kettle is of copper, neatly finished to a simple design, and has a capacity of three pints. Each kettle has only one degree of heat, but can be supplied with either a 250-watt heating unit for boiling water already warm, or with a 500-watt unit for raising cold water to the boiling point in a short time.

Wireless Telegraphy in Madagascar.—A wireless telegraph station is to be constructed on the island, and a large quantity of apparatus has already been despatched from France.

Electricity Supply in Winnipeg.—The statement, published in London, that the Winnipeg City Council has voted a sum of £2,600,000 towards the purchase of the tramway and lighting plant of the city is incorrect. A motion was introduced in the Council to investigate the question, but no action was taken.

X-ray Dermatitis.—The head of the X-ray department of the London Hospital (Whitechapel), Mr. Ernest Harnack, has recently undergone three operations, consisting of the amputation of fingers of both hands. An appeal for financial help is being made on behalf of Mr. Harnack, who has a family dependent upon him.

Borough Polytechnic Institute.—The annual exhibition of students' work took place on Saturday last. Some excellent examples of technical work by evening students were on view in the large drawing office. Amongst the exhibits of an electrical nature were some model armatures illustrating the various types of windings, and in the electro-chemical laboratory a very neat little piece of apparatus, designed by Dr. F. Mollwo Perkin, head of the Chemistry Department, for the quick electrolytic analysis of salts, was on view. In this apparatus advantage is taken of the fact that by rotating the kathode the metal is deposited at a faster rate than when the kathode is stationary. An analysis which by the latter method would take three hours can, by rotating the kathode, be done in less than half an hour.

The Poulsen System of Wireless Telegraphy and Telephony.—According to the *Elektrotechnische Zeitschrift*, the ss. *United States*, on a voyage to America, kept up a reciprocal communication with the station at Cullercoats until a distance of 1,350 miles was reached. The height of the mast of the *United States* is 92 ft., and the capacity of the dynamo 3 5 kw. The Cullercoats station has a 5 kw. dynamo. It is also stated that the Lyngby station (see Electrical Engineering, March 26th, page 469) is in regular communication by wireless telephony with the Esbjerg station in south Jutland, a distance of 170 miles. The former station has a 10 kw. dynamo, the latter a 6 kw. dynamo. The telephonic reception was clear and good, and there was practically no distortion of the wave shape.

A NEW LAMP HOLDER

THE accompanying illustrations show a new form of lamp holder and cap on what is known as the "Bruston" system, which is being put on the market by Leo. Sunderland & Co., of 39 Victoria Street, S.W. It is claimed that this is the only lamp holder in which terminals of opposite polarity are entirely separated and enclosed in porcelain pits both in the holder and in the lamp when in use. By this means not only is the liability to burn out, which some badly constructed lamp holders possess, entirely avoided, but remarkably high insulation resistance is shown from terminal to terminal or between one terminal and the brass case; and this is so even after the whole has been immersed in water with the lamp alight. The construction of the holder and the special lamp cap for use with it is apparent from the sketches herewith. It will be seen that the springs are contained in the lamp cap instead of the holder itself, and

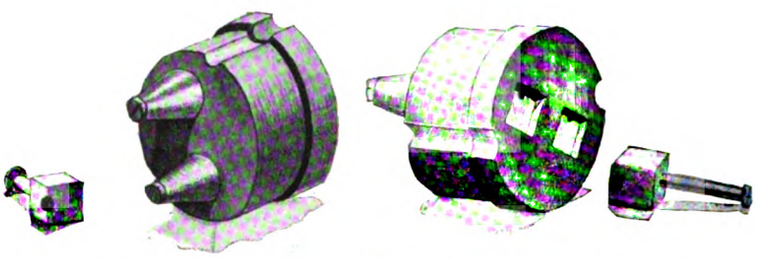

Fig. 1.—Insulator and Contact Pins of Lamp Holder, showing terminal blocks and screws separately.

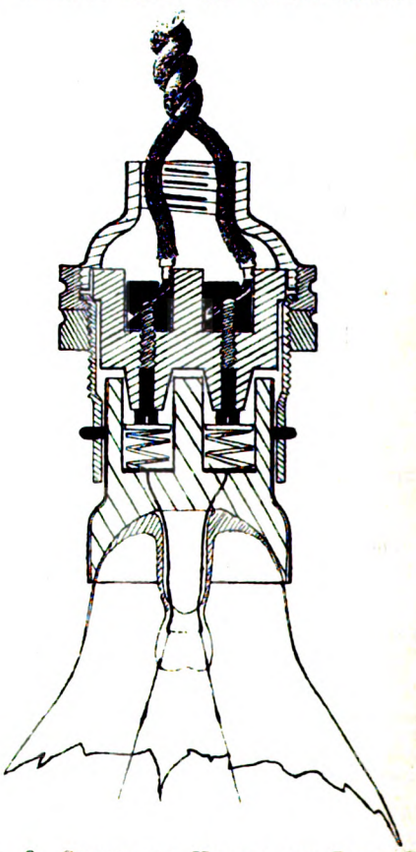

Fig. 2.—Section of Holder and Lamp Cap.

that all metal parts carrying current are embedded in porcelain or vitrite pits. The arrangement is particularly recommended for use in damp situations, as condensed moisture draining into the pits will be of little consequence, and for traction work, where the sparking caused by imperfect contact due to vibration is confined to the porcelain pits. The connections are so arranged that it is impossible for stray strands of flexible wire to cause short circuits.

Mexican Telephone Service.—According to an American Consular Report, a company is being formed for the purpose of developing long-distance and wireless telephony between Mexico City and the port of Veracruz. A concession covering a period of 50 years has been obtained. A few miles of underground work have already been laid in Veracruz. The towns in the State of Veracruz will next be connected by overhead wires, and later the wireless system will be developed.

SUMMARY

The scheme for a joint electrical exhibit of several firms at the Franco-British Exhibition has been abandoned. (Page 579.)

Traffic has been commenced on the single-phase system on a portion of the Lancashire lines of the Midland Railway. This is the first instance of single-phase railway traction to be put to work in England. (Page 580.)

Mr. Eustace Thomas read a Paper on Tuesday before the Manchester Local Section of the Institution of Electrical Engineers on the management of engineering workshops, in which he dealt with some of the general principles by which economy may be obtained in manufacturing works, especially as regards shop routine, lists of materials, drawings, records, &c., and the day work as compared with piece work or premium systems. (Page 580.)

A Paper on the effect of metallic filament lamps on the electricity supply industry was read by Messrs. H. W. Handcock and A. H. Dykes last Thursday at the Institution of Electrical Engineers. Figures were given as to the reduction in consumption, especially when employing auto-transformers and 25-volt Osram lamps. The authors proposed to reduce the effect on the station revenue by the introduction of a new system of charging, by which the consumer would be charged a fixed sum per annum, depending on the maximum current he requisitioned on signing his contract, and a certain charge per unit in addition. They proposed the employment of a "limit indicator," which would dim the lamps when the contract maximum was exceeded. Mr. Arthur Wright opened the discussion by deprecating such advertisements as "70 per cent. discount on your bills," instead of "three times the light for the same bill." He pointed to the enormous increase in business which would accrue through cheaper light and to the necessity of reducing the cost of service connections. At present it cost nearly as much per kw. to connect a house as to build a station. Mr. Hugo Hirst announced a Paper on the evolution of the metallic filament lamp, which he had just sent in to the Institution. Incidentally he stated that new Osram lamps could now be paired with old. He thought there was no need to resort to the panic measures suggested by the authors. Mr. Bottomley Smith did not approve of the proposed "contract demand" system of charging. Mr. W. R. Rawlings, as an electrical contractor, objected strongly to the Wright system of charging, and favoured the authors' system. Mr. F. M. Long described a system in use at Norwich, in which the consumer is charged an annual sum of 12 per cent. of the net assessment of his house *plus* 1d. per unit. The Paper was also discussed in

Digitized by Google

Dublin on Thursday. The London discussion will be continued on April 23rd, and there will be a discussion at Glasgow on May 12th. (Page 581.)

THE extension of the Kingsway tramway subway from Aldwych to the Embankment, which forms the connecting link between the northern and southern systems of the London County Council tramways, was opened on Friday last. (Page 585.)

THE total number of units sold by the North Metropolitan Electric Power Supply Co. during the year ended December 31st, 1907, shows an increase of about 40 per cent. over the figure for the previous year. The accounts show that the average total costs, not including capital charges, were 0·865d. per unit. (Page 586.)

A VERY successful motor hiring department has been established by the Birmingham Corporation Electricity Department. Very complete arrangements are made as to testing, installation, and inspection. (Page 587.)

THE manufacture of tungsten incandescent lamp filaments, including that of the new "Z" lamp, was dealt with in a recent address by Dr. CLAYTON H. SHARP before the American Electrochemical Society. (Page 588.)

THE India Rubber, Gutta Percha, and Telegraph Works Co. have been experimenting for some time on electrical automobiles, and have now brought out a perfected "Silvertown" electric carriage for town use. The principal features of its design are the use of a four-wheel drive by two geared motors and live axles, and a controller giving as many as thirteen positions, including three electric braking notches. (Page 589.)

AN ingenious form of new arc-lamp coupling is described. (Page 591.)

A NEW metallic filament lamp, which is of British invention and British manufacture, will shortly be put upon the market. The filament consists of tungsten alloyed with other metals, and is ordinarily run at one watt per candle. 100-volt 17-c.p. and 200-volt 34-c.p. lamps will be obtainable. (Page 592.)

THE Paper on heating of ventilated and enclosed motors, read last Thursday before the Leeds Local Section of the Institution of Electrical Engineers, dealt generally with the dissipation of heat produced by motor losses and the effect upon this of different degrees of enclosure, and described some tests on an experimental machine. The author expressed the opinion that totally enclosed motors suffer from great disadvantages, but that their use can in general be avoided. Reference was made in the discussion to the enclosure of motors in large gauze cages, and the use of enclosed motors in mines. (Page 593.)

THE Paper by Mr. G. G. STONEY and Mr. A. H. LAW on high-speed electrical machinery, read on April 2nd at the London meeting of the Institution of Electrical Engineers, has been further discussed by the Newcastle Local Section. The broad principles of the designs described were less freely criticised than at the London discussion, and more attention was paid to matters of detail. (Page 595.)

THE Highways Committee of the London County Council report in favour of putting the Hammersmith-Putney tramways, which will be upon the overhead trolley system, in hand immediately. An estimate on capital account of £34,000 is approved by the Finance Committee. (Page 597.)

UNDER "Electrochemistry and Electrometallurgy" we notice methods of producing glass in the electric furnace and the various methods which have been employed for preparing calcium carbide. The interesting subject of electrolytic zinc galvanising is also discussed, and figures are given which show that the electrolytic galvanising, at any rate on paper, is considerably cheaper than the hot dipping process. (Page 597.)

LORD RAYLEIGH has been elected Chancellor of Cambridge University in succession to the late Duke of Devonshire. Under "Electrical Science," in the British and American Section, are notes on some newly-found induction coil phenomena and on the carriers of positive electricity. An account is also given of Prof. J. J. THOMSON'S concluding lecture at the Royal Institution on Saturday on "Electric Discharges through Gases." The lecturer explained the phenomena met with in the discharge through exhausted tubes, including the striation effect, and the sudden cessation of the discharge on a slight increase of resistance in the circuit. Some remarks on the electric arc, which, Prof. THOMSON said, was a case of discharge from an incandescent solid and not a discharge through a gas, concluded the lecture. The scheme for an Indian Institute of Science is progressing. In the Papers abstracted in the Continental Section, BOUQUET DE LA GRYE proposes to establish an international wireless hour signal to cover the whole globe, and BOSLER redetermines the number of electrons in an atom. (Page 597.)

AMONGST the patent specifications published on Thursday last is one by the BRITISH THOMSON-HOUSTON Co., describing a method of avoiding the use of compensating windings of any sort in the interpolar spaces of commutator motors by providing the armature with a fractional pitch winding. A commutating field is produced at the main pole-tip. A specification by J. S. HIGHFIELD relates to a modification in the high-tension continuous-current series system; the prime-mover is a single large turbo-alternator supplying current to a number of rotary-converters, the direct-current sides of which are in series. BRUCE PEEBLES & Co. and LA COUR have patented an improved method of using amortisseurs. (Page 599.)

IN consequence of the Bangor Council insisting upon increased rent for the poles of the National Telephone Co., the latter has threatened to discontinue the service in Bangor.—An action is to be taken by some of the authorities in West London against the London United Tramways, Ltd., for an injunction in respect of alleged nuisance from noise from the tramcars.—In a communication to the Edinburgh Chamber of Commerce the Postmaster-General states that but for difficulties in obtaining the consent of the Edinburgh Corporation to the execution of the underground work, the underground telegraph line from Linlithgow to Edinburgh would have been completed long ago.—The accounts of the Launceston (Tasmania) Council for the year 1907 show a net balance of £8,770.—The Finance Committee of the London County Council gives figures showing the amounts sanctioned during the financial year 1907–8, and the preceding years, for electric lighting loans.—Permission has been granted to the Newcastle Electric Supply Co. by the Tyne River Commissioners, to lay a 6,000-volt cable under the river Tyne, between Carville, Wallsend, and Hebburn.—Messrs. Kincaid, Waller, Manville and Dawson have reported to the Torquay Corporation with regard to meeting the extra demands from the Tramways Co. Two alternative schemes have been presented, one of which involves the transfer of some of the plant of the present station to another site, and the other the erection of a new station. (Pages 601–604.)

THE Aberdeen Corporation is to apply for sanction to borrow £80,000 for extensions to the electricity undertaking. Local Government Board inquiries with regard to loans for electric lighting purposes have been held at Aston (£25,213) and Canterbury (£4,000). The London County Council require 175 double-decked roof-covered car bodies with maximum traction trucks and complete electrical equipment for the overhead trolley, surface contact, and underground contact systems for the same. Applications are to be made to the Local Government Board for loans for electric lighting purposes as follows:

Digitized by Google

—£7,942 by the Morley Corporation, £22,696 by the Wigan Corporation, and £1,700 by the Whitehaven Corporation. The British Thomson-Houston Co. is supplying a 1,500 k.v.a. exhaust steam turbine at 2,875 volts 40 cycles to the Tyneside Electrical Development Co., to be worked in connection with the Teesbridge Iron Co. (Pages 604, 605, and 583.)

The directors of the Anglo-Argentine Tramways Co. propose to make an issue of £500,000 new debentures very shortly. The accounts of the Bath Electric Tramways Co. for 1907 show a balance of £13,749, and after deducting the interest on the 4½ first mortgage stock interest and dividends on the preference shares, the balance of £24,890 is to be carried forward. At the annual meeting of the British Electric Transformer Co. last week, an amendment that the report be received but not accepted was carried, and a poll is to be taken. The accounts of the Calcutta Tramways Co. for 1907 show a revenue balance of £63,333 and a net balance of £18,979, out of which a final dividend of 2s. 6d. per share is to be paid. A scheme for dealing with the profit-sharing notes of the Underground Electric Railways Co. of London has been published. Sir George Gibb has been appointed receiver and manager in the temporary voluntary liquidation which is necessary. (Pages 606 and 608.)

The habit of grumbling, practised in moderation, is inborn in every British citizen, and is not a bad thing in its way; but when a habit is indulged in to excess, it invites either ridicule or disaster. We trust that the former and not the latter will be the result of the foolish attitude taken by some Jeremiahs in the electrical world, who foretell disaster to the supply industry because of the advent of an electric lamp three times as efficient as the one we have had hitherto. That, in some cases, the receipts from the sale of electrical energy are momentarily falling off has perhaps been unavoidable, but it is absurd to waste valuable time on lamentations when all available energy should at once be devoted to making the utmost of the inventions which have now made electric lighting far and away the cheapest of all illuminants. Doubtless the revolutionary change in the electric lighting industry which the metallic filament lamp is bringing about will necessitate a large amount of adjustment in the details of electricity supply practice. The most important of these must be the employment of cheaper methods of connecting up house services. At present, as was pointed out by Mr. Arthur Wright in the discussion on Messrs. Handcock and Dykes' Paper, there are cases in which it costs almost as much per kw. to connect up a consumer as to build the electricity works that is to supply him. Probably the old contract system of charging a fixed sum per lamp per quarter will have to be reverted to in the case of the numerous small consumers, who will be attracted by the cheaper light. This system, in the light of modern knowledge of the cost of electric supply, is not so inept as is sometimes thought, for, if it is assumed that the consumers' lamps are on during the period of peak load, the exact computation of the time they are employed on either side of the peak is less important, as the cost of supplying is then much lower. On the other hand, an introduction of any other system of charging than the flat rate or on contract would be a great mistake when it is a question of winning over the small consumer from gas by proving to him that his light will cost him less. Neither Messrs. Handcock and Dykes' "contract demand" system nor Mr. Long's "assessment tariff" should be thought of in such cases, and the maximum demand indicator should be reserved for the large and intelligent power consumer, or used only as a measuring instrument for the information of the central station engineer and manager. Now is certainly not the time to introduce new systems of charging, and the only method we dare suggest to the supply station manager for saving his profit during the next few months is to increase slightly his meter rents; but even this suggestion we put forward with some diffidence. The metallic filament lamp will be the means of lifting the electrical industry out of its present depression by an enormous extension of electric lighting all over the country. It means a large increase in the number of members of the general public who are direct customers of that industry, and any step tending to retard this increase artificially is strongly to be deprecated.

Although many excellent reasons were advanced for the electrical industry having a representative exhibit at the forthcoming Franco-British Exhibition, electrical firms have shown from the outset a disinclination to take part in it. To some extent this was due to a feeling that the exhibition at Shepherd's Bush would take rather the form of a pleasure garden than an industrial exhibition, but the main reason was that the electrical firms are reserving their energies for their own exhibition to be held in Manchester next October. By dint of great perseverance on the part of Dr. R. T. Glazebrook, last year's President of the Institution of Electrical Engineers, and Mr. C. S. Northcote, supported by the electricity supply interests in London, arrangements were practically concluded for a joint exhibit of electrical manufacturers, but we learn that at the last moment the whole scheme has fallen through, owing to unfortunate delays and the lack of interest that has been displayed from the outset. The original proposal was that there should be a regular electrical section, and circulars were sent out by the secretary of the Institution of Electrical Engineers on behalf of Dr. Glazebrook, who was to be chairman of the section. There was practically no response to this, but as it was understood that the gas interests would be very well represented indeed, it was thought that the matter should not be allowed to drop, and the electricity supply undertakers in London promised to contribute to the expenses of a joint electrical exhibit, if a sufficient number of electrical firms could be prevailed upon to take part in it. The matter proceeded very slowly, but finally some twenty firms, including many of the large ones, made formal application for space. Then difficulties arose between the committee for the joint exhibit and the organisers of the exhibition on points of detail with regard to the allotment of space, and even last week we believe the matter was not definitely settled. The result was that the majority of the larger firms who had intended to exhibit announced their intention of withdrawing, and as actually only twelve of the smaller firms were left, the supply companies decided that it would not be worth while supporting the joint exhibit financially, and the whole thing has fallen through. The large firms who have withdrawn and the electricity supply companies cannot be blamed for their action, since it is evident that owing to the intervention of the Easter holidays, no really good electrical exhibit could have been erected between the present date and the opening of the exhibition on May 1st.

THE MANAGEMENT OF ENGINEERING WORKSHOPS

MR. EUSTACE THOMAS'S Paper, read on Tuesday at the Manchester Local Section of the Institution of Electrical Engineers, contained the impressions of the author regarding details of organisation and record-keeping in a number of manufacturing works which he had recently visited. Most of these were specialised shops, where the work was almost wholly standard, and the greater ease of running works of this nature as compared with general shops was emphasised early in the Paper.

It is generally agreed that the workman in every case should have a drawing to work to, fully dimensioned; that is, that the workman should have only manual work, and all head work should be done by the draughtsman or designer. On the same principle a complete detailed list of material should be prepared in the office, instead of the material being requisitioned from the drawing by the foreman or the workman without a list. The workman becomes a head worker, and he is usually a very inefficient and expensive one. Moreover, a list *must* be got out by some one, and if this is done in the works it will have to be thought out and written out every single time that the job repeats itself. The certain result is preventable expense and loss of time. The list should be prepared in the office even if only one article is to be made, but in such form that it may be readily available for any future work.

A still further application which is only seldom made is that there should be provided also a list of operations and list of tools, jigs, &c., in every case where a new workman might possibly be in doubt. This applies particularly in some classes of switch work.

In speaking of the duties of foremen, the author classifies these as (1) *Clerical or Administrative*, such as giving out work, seeing that there is no delay caused by waiting for material; watching the efficiency of the workmen, planning to get work executed to time, &c., &c.; and (2) *Technical*, such as the consideration of methods, tools, and jigs, for executing work, for overcoming difficulties, for reducing cost of production, &c.

The author inclined towards giving the foremen chiefly administrative work, but he must be technical enough to know if matters are not going rightly, and in such set an expert toolfitter to study the case and do what is required. The value of a certain amount of "red tape" in defining and ensuring correct routine was pointed out, although such routine is useless unless kept up by constant supervision and periodical inspection of the works by the manager. The value of brain-saving devices in the cost departments was also mentioned.

Lists of material can be made to serve several important purposes, for example:—The storekeeper marks it for material in stock or to order. The stores issue goods from it to the foreman's auxiliary stores without further requisition. The foreman can check by it all material at any stage. The drawings having been cut up into as many parts as there are pieces or groups of pieces to be made, a copy of the list is also cut up and pieces attached to the divided-up drawings for the workmen's use. On a further copy, against each item is marked the time by which it must be completed, in order that the whole of the work may go through to the date desired. Each shop foreman must have his own copy marked. A copy goes to the cost department. The work can be priced against this list in advance if required, and actual issues and returns can be checked against it. Where work is executed in different shops, it is of assistance to subdivide the list accordingly. Any assembled parts which may be used for other work are best given separate lists, as they may be manufactured for stock.

The advantages of the provision of proper type numbers to standard parts are pointed out, and it is recommended that the utmost care should be taken ensuring the return of unused material to the stores, and recording materials scrapped through fault in the material, labour wasted through fault in the material, labour wasted through faulty workmanship, material wasted through faulty workmanship, and cost of putting any jobs right if that is possible.

Shop drawings should consist of pieces of cardboard carrying that part of the drawing required for any one piece or group of pieces given out to one man only at a time. On the same card is the list of material, cut off the general list, the list of operations, and the list of tools, gauges, jigs, &c. The separate cards are numbered serially and usually kept together. Those required for a job are distributed in the auxiliary stores in the space allotted. There should be some material to each card, if all material has been collected.

The Paper then goes on to deal with day work and piece work. The following are given as some disadvantages of day work, especially in general shops:—The men slack off as soon as the foreman's vigilance relaxes at all. Some men regard it as a matter of principle to make jobs last as long as possible with a view to increasing employment. The men are quite content to wait for material. The handling of material by the foreman is always less efficient. Costing is uncertain and unsatisfactory.

Some advantages of premium or piece work are:—Each man has an interest in the work. The men press the foreman to give efficient delivery of material, and the foreman is thus placed between two fires. Each job *must* have careful consideration before being committed to a price or time which may be hard to change. Each job makes the estimation of new work easier. The foreman has more time to plan his jobs and is better able to estimate for and keep correct promises of completion. If the assemblers are on piece or premium work, they draw attention themselves to any inaccurate manufacture of parts coming to them.

The question of saving "non-cutting" time taken up in gauging, setting up, changing tools, &c., is then considered, and it is pointed out how attention to detail may considerably shorten this.

In a general shop having many small jobs in hand at once it requires a very clever foreman to give times of completion of all work in hand which he can adhere to, and yet not have too much labour employed. The author has devised a special indicator for the purpose, which gives the foreman a bird's-eye view of the work in hand, and of the capacity for work. It requires that time shall be estimated on all work in detail, whether on the day, piece, or premium systems. One or more suitable boards are laid out with horizontal grooves to represent the different men in classes according to employment, wages, &c.; some spare grooves are also allowed to each class. Vertical lines are drawn to scale to represent hours, days, and weeks. Fairly narrow strips of card are cut off for each job, of length equal to the number of hours estimated, and marked with the job number and date by which completion is required. These are then set up in the grooves, always to the left of the date marked on them. If there is more work in hand than capacity in men some cards must go into the spare grooves. The card to the left in each groove is always the job in progress at the time with that man, those to the right being arranged in the order of present urgency. They can be reshuffled later as altered circumstances may seem to require. Thus the foreman or manager can see at a glance what work is likely to be late, what is the present capacity for new work, stock work, &c., what jobs are hanging, and where it is desirable to take on or discharge men. The material labourer can also see what materials, tools, &c., are likely to be required soon, and get them ready.

Institution of Electrical Engineers.—The meeting on Thursday next, April 23rd, will be held in the Institution of Mechanical Engineers' building. Messrs. Handcock & Dykes' Paper on the effect of the metallic filament lamp on the electricity supply industry will be further discussed.

The First Overhead Single-phase Railway in England.—The experimental use of single-phase traction on the Morcambe-Heysham branch of the Midland Railway was taken into use last Monday. An overhead single-phase system at 6,000 volts is used with catenary suspension. The line is the first overhead single-phase to be put into operation in this country.

Electrotyping.—On Thursday night Mr. Sherard Cowper-Coles read a Paper, entitled "Some Notes on Electrotyping," at the London County Council School of Photo-Engraving and Lithography. The chief features dealt with were the conditions necessary for the rapid electro-deposition of copper on the moulds, and the various effects obtained by mechanical and chemical treatment.

Damage to an Electric Light Standard.—The Islington Borough Council sued the London Road Car Co., at the Clerkenwell County Court, on Friday, for £30 5s. damage to an electric light standard. It appears that on May 31st last a Union Jack motor-omnibus skidded in Highbury Grove and collided with an electric light standard on the foot-path, breaking the column. The driver of the 'bus stated that he was driving at about seven miles an hour, and that the omnibus skidded on account of the greasy condition of the road. In the end the jury found for the Borough Council for the full amount claimed.

EFFECT OF METALLIC FILAMENT LAMPS ON THE BUSINESS OF ELECTRICITY SUPPLY

At the Institution of Electrical Engineers last Thursday, a Paper was read by Messrs. H. W. Handcock and A. H. Dykes with the title "Electric Supply Prospects and Charges as affected by Metallic Filament Lamps and Electric Heating." The authors pointed out that, with the new metallic filament lamps giving from 23 to 30 c.p. at 110 volts with a consumption of 40 watts, consumers will in some cases be able to do with fewer points and thus reduce their consumption, whilst in other cases they will merely improve their lighting without greatly reducing their consumption. So far as private consumers are concerned, the authors are of an opinion that, owing to the high price of the lamps and the fact of their being only available in comparatively large units at about 100 volts, the lamps will only be adopted at present when the consumer is sure that the total lighting bill will be reduced or, at any rate, not increased. Where a large proportion of the points are at present single lights with separate switches for each point, the saving in current by using two lamps in series would not, they think, be great enough to ensure the general adoption of metallic filament lamps at present. On the other hand, in the case of shops, halls, and factories where the lamps are mostly on all at once, even if the same total number of the lamps is used, the current consumption would be reduced by about one-third, with an increase in the illumination of 50 per cent. or more.

The authors state that when the lamps are run in series, their life depends very much on the fluctuation in voltage on the circuit, and under ordinary conditions is considerably less than when the lamps are in parallel. The 100- and 110-volt Osram lamps are said to have a useful life of 750 hours, but in calculating the cost of lamp renewals it must not be forgotten that breakages in transit are a serious item. In the case of Tantalum lamps a 750-hour life is also guaranteed, whether lamps are run in parallel or two in series; but in the latter case it is conditional on the lamps being properly paired, that if one burns out both be replaced (the partially worn-out one paired with another which is partially worn out), and that the voltage of the lamp corresponds not with the declared voltage, but with the highest voltage actually occurring on the circuit in question.

Coming to the effect of the decreased consumption on a supply station when these lamps are used, the authors point out that if, for instance, the consumption per consumer is reduced by one-third, it is not sufficient, in order to obtain the same profit, to increase the number of consumers by 50 per cent., as this only keeps the output at its former figure without allowing for the increased capital outlay on services, meter reading, and general administration.

The Paper next deals with the use of 25-volt metallic filament lamps supplied from the alternating current mains through an auto-transformer. In their own private houses the authors have made use of such an arrangement, connecting in each case an auto-transformer across the 200-volt supply main and taking off from it eight circuits of 25 volts each. This lower pressure permits the use of 25-volt metallic filament lamps of 8 and 14 British candle-power, which are cheaper in first cost, more efficient, and stronger than the 100-volt lamps. The 8 c.p. 25-volt Osram lamp is rated at 10 watts, and the 14 c.p. at 16 watts. They have tested transformers made by different makers, each wound for 8 circuits of 25 volts, and 4 or 5 amperes per circuit for use on 25-volt 50-period mains, and they have found that the no-load consumption with all lamps turned off is from 12 to 15 watts. In order to save this loss in the daytime and during the night, they have placed two-way switches on the ground and bedroom floors, by means of which the transformers are switched off the last thing at night and only turned on again on the ground floor when the lamps are required again next day, and they use carbon filament lamps in the bedrooms. They state, however, that there is now on the market more than one device which will switch the transformer off when the last lamp is turned off, and switch it on again when the first lamp is turned on. They have found that the consumption in their houses is only from one-third to one-half of what it was formerly. The smaller lamps can be used in any position, and are of ordinary size, so that they can fit any ordinary shade. Their price is 3s. instead of 4s., and an electrolier with six 8-c.p. lamps only consumes the same amount of energy as an ordinary 16 c.p. carbon filament lamp.

Some comparative tests were made by a large firm in London on a portion of their installation, consisting of fifty 8-c.p. lamps. With the carbon filament lamps the meter reading over two hours was 3·25 units, whilst with an auto-transformer and 25-volt 8-c.p. Osram lamp the reading for the same period was only 1·10 units.

This arrangement could, of course, not be used with continuous current, but 50-watt 40-c.p. 200-volt lamps are now being placed on the market.

The authors next compared the effect of the reduced consumption on the supply station with the effect of the introduction of the incandescent mantle in the case of gas lighting. They find in the Board of Trade returns that the total capital expenditure in the whole country on gas undertakings has been £124,184,000, the gross revenue £27,254,000, and the gross expenditure £20,496,000. For electrical undertakings the figures are:—Gross capital, £50,767,000; gross revenue, £6,514,000; and gross expenditure, £3,019,000. This works out to an expenditure of £4 10s. for a gasworks, or £7 10s. for an electricity works, in order to obtain the gross revenue of £1 per annum. Owing to the higher capital expenditure, there has to be a greater percentage difference between the income and expenditure in the case of the electricity works than in the case of the gasworks, as the larger capital charges have to be added to the total cost of generation. In addition to this, an electricity supply company is generally liable to be bought out at a sum representing far less than its capital expenditure after a 42 years' life, and has therefore to provide a substantial sinking fund. Another disadvantage from which the electricity undertaking suffers is that the consumer's service line, exclusive of meters, costs far more than for gas. The authors place the figures at £5 to £6 in the case of electricity, and £1 to £1 10s. in the case of gas. Moreover, if supply is required for heating, an additional expense has to be incurred for additional meters and wiring. From these figures the authors deduce that, supposing a gas and electricity company each lose 20 per cent. of their business, the gas company would have to raise its price by 6·25 per cent. in order to keep their profit at the same figure, whilst the electricity company would have to increase its price by 13·4 per cent. The opinion of gas engineers is quoted to the effect that it was the increase in gas cooking and heating which "saved" the gas companies when the gas mantle was introduced. The average annual revenue per gas consumer throughout the country works out from the Board of Trade returns at £5 8s., and the authors cite an extreme case

Digitized by Google

in which the gas company is paying the full statutory dividend of 10 per cent., although a large proportion of the consumers have only about six lights in use, and their bills, including meter rents, did not average more than £1 16s. per annum.

The Paper next analyses the total saving in the case of a large London firm alluded to previously in the Paper, which had substituted 25-volt metallic filament lamps supplied through an auto-transformer for carbon filament lamps. They had 686 eight c.p. lamps consuming originally 36,260 units per annum, and they paid the average price of 3·47d. per unit. Their annual account came to £604 12s., of which the cost of electrical energy was £524, and the lamp renewals (1,612 lamps at 1s.) £80 12s. With the 25-volt Osram lamps only 12,500 units were consumed per annum, so that, assuming the same price of 3·47d. per unit and the same life for the lamps, the annual cost would be £422 10s. 7d., of which £180 14s. 7d. would be paid for electrical energy and £241 16s. for lamp renewals (1,612 lamps at 3s.). The lamp-makers receive in the latter case about three times as much as formerly, whilst the supply station has lost 65 per cent. of its business. As a matter of fact, the difference was not quite so great in the case in question, as the installation is supplied on a sliding scale depending solely on the quantity consumed, so that the bill for electrical energy came to £205 2s. (10,000 units at 4d. per unit, and 2,500 units at 3½d. per unit) instead of £180, and the total, including lamp renewals, was £446 18s. If the firm had been charged on the maximum demand system, the maximum demand would, of course, have been reduced in the same proportion to the total consumption, and the price per unit would have remained at 3·47d. instead of there being a slight increase.

The authors next turned to the main point of the Paper, namely, a proposal to revise the system of charging, so that the reduction in current consumed due to the use of metallic filament lamps will not affect the electricity supply business so seriously as they think is otherwise threatened. They favour a system in which it is not necessary to put in a separate meter when current is used for power, heating, &c., in addition to lighting, as this presents obvious advantages both to the supply undertaking and consumer. In the system they propose, a consumer, when he applies for a service, will state as at present the number and candle-power of the lamps he proposes to use, and the station manager will estimate from this the probable maximum demand. This the authors call the consumer's "contract demand." The consumer is to pay a fixed annual sum, depending on the amount of this "contract demand," and, in addition, a certain price per unit. The authors give the following examples as to how the prices work out in practice:—

A certain alternating-current station has a maximum load of 713 kw. on the station feeders, and the sum of the consumers' "contract demands" would probably be found to be about 990 kw., depending on the nature of the load supplied.

	£
The interest and sinking fund charges absorbed	6,203
The rest of the "preparation costs"* amounted to	4,449
Giving a total of	£10,652

This divided by 990 gives £10 15s.† as the standing charges per "contract" kilowatt demanded. The "production costs" per unit were 0·87d., say 0·95 pence, allowing a margin for profit.

The charges would therefore be £10 15s. per "contract" kilowatt demanded, and 0·95d. per unit consumed.

As an illustration take two typical houses, A and B:—

"A" has an equivalent of 60 lamps of 8 c.p., and consumes 655 units at 5½d. per unit, the present flat rate = £15.

The "contract demand" would probably be fixed at 0·9 kw., and the charges under the new system would therefore be—

	£	s.	d.
0·9 kw. at £10 15s. per kilowatt	9	13	6
655 units at 0·95d. per unit	2	11	10
Total	£12	5	4

= 4·5d. per unit.

"B" has an equivalent of 55 lamps of 8 c.p., and consumes 350 units at 5½d. per unit, the present flat rate = £8.

With the "contract demand" fixed at 0·9 kw. the charge would be—

	£	s.	d.
0·9 kw. at £10 15s. per kilowatt	9	13	6
350 units at 0·95d. per unit	1	7	8
Total	£11	1	2

= 7·58d. per unit.

The tramways take 360,000 units per annum.

Assuming 100-kw. "contract demand" the charges would be—

	£	s.	d.
100 kw. at £10 15s. per kilowatt	1,075	0	0
360,000 units at 0·95d. per unit	1,425	0	0
Total	£2,500	0	0

= 1·67d. per unit.

Take next a shop as an example:—

Lamps installed, say, 20 of 40 watts each, consuming, say, 400 units per annum.

"Contract demand," say, 0·8 kw.

The charge would be—

	£	s.	d.
0·8 "contract demand" at £10 15s. per kilowatt	8	12	0
400 units at 0·95d. per unit	1	11	8
Total	£10	3	8

= 6·11d. per unit.

As applied to a motor load, take, for example, a 10-h.p. motor giving a variable load for, say, 50 hours per week.

The charge would here be as follows:—

	£	s.	d.
"Contract demand," say, 10 kw. at £10 15s. per kilowatt	107	10	0
Say 13,500 units per annum at 0·95d. per unit	53	8	9
Total	£160	18	9

= 2·86d. per unit.

This consumer cannot be profitably charged at a lower figure, even on a flat rate, as he has the privilege of coming on at peak load. If, however, the consumer would agree not to work his motor during lighting hours, or, at all events, during the period covering peak load, but not otherwise, his rate per "contract kilowatt" demanded should be fixed as a matter of equity at, say, £5 per kilowatt.

His account would then become—

	£	s.	d.
"Contract demand," 10 kw. at £5 per kilowatt	50	0	0
13,500 units at 0·95d. per unit	53	8	9
Total	£103	8	9

which represents 1·84d. per unit instead of 2·86d.

In order that the consumer does not exceed his "contract demand," the authors propose to insert in every house a "limit indicator," the function of which is to throw a resistance into circuit when the above demand is exceeded, and thus to give the consumer an indication of the fact by reducing the brilliancy of his lamps. If the consumer has under-estimated his "contract demand," he would, it is assumed, ask to have his indicator set higher.

The authors point out that there are at present two difficulties in the application of the above system. Section 31 of the Electric Lighting (Clauses) Act provides that in the event of the undertakers charging by any special method (which must be approved by the Board of Trade), any consumer has the right, by giving one month's notice in writing, to require the undertakers to charge him by the actual amount of energy supplied to him. Moreover, in most Electric Lighting Orders the Board of Trade has fixed the maximum charge for any

* The authors define "preparation costs" as the costs which are independent of the actual output of the station, including, in the case of companies, a reasonable dividend.

† By taking 990 kw. instead of 713 kw., the maximum load on the station feeders, the consumer gets due allowance for the Diversity Factor

Digitized by Google

amount up to 20 units at 13s. 4d., and for each unit over 20 units 8d. (In some cases the rate of 7d. is substituted for 8d.)

In concluding the reading of the Paper, Mr. Handcock read the following remarks:—

Only a few months have elapsed since this Paper was written, but much has happened meantime. Two metallic filament lamps are now being sold to every one carbon filament lamp, and many matters that were then surmise can now be tested by actual results, and a fairly close answer given to many points that our Paper raises. These results entirely confirm our views as regards the individual consumer, and they also demonstrate that the effect of metallic filaments is so complex that generalisation is impossible.

On no two stations are the effects the same; in some cases the first quarter of this year has been better than ever; in others, the normal rate of increase has not been maintained; while others again report a lower peak load than in 1907.

From the very fact that the "light-supplying capacity" of stations has been doubled or trebled at a stroke, the demand for new plant will be small until matters have readjusted themselves. As against this, the lamp-makers will reap a well-earned harvest of their labours, and installation contractors will share their prosperity. For the investor in electric light undertakings, there is the reassurance that any dislocation can only be of a purely temporary nature, as even if the consumer, who now pays 5d. per unit, for instance, were called upon to pay double that amount, his electric light would even then cost him less than it did with carbon filaments. This is a fact we must always keep before us. Provided that the situation is properly dealt with, as it doubtless will be, it is a fact that leaves room for no fear as to the future, for, after all, electric light stations must be judged, not by "units sold," but by "dividends paid."

In a short note at the end of the Paper, the author referred to a system of charging introduced by Mr. F. W. Long, City Electrical Engineer, of Norwich. Consumers have the option of taking a supply either at a flat rate of 4½d. or at what is called an "assessment tariff." Under the latter, the consumer pays a fixed charge of 12 per cent. upon the net assessment of his house and a 1d. per unit for current used. It will be seen below that Mr. Long spoke in the discussion and referred to the system at greater length.

Mr. Dykes also added some remarks. He desired particularly to emphasise two points. The first was the advisability of alteration in the present methods of charging, which had been apparent to the authors for some time, and had only been accentuated by the advent of metallic filament lamps. When a manufacturer found he could no longer supply his goods at the old prices, he must either raise his prices all round, or must rearrange them so that the greater part of the increase is borne by his most unremunerative customers. At the same time, he must try to open up new avenues for the sale of his goods. This was what the "Contract Demand" system endeavoured to carry out, by putting the increase on the short-hour consumer, and encouraging the use of current for other purposes besides lighting. The second point Mr. Dykes desired to make clear was that the authors were not pessimistic as regards the future of the electric supply business if the new conditions are properly grappled with. Take the case of a consumer now getting current at 5d. per unit and paying one shilling each for his 8-c.p. carbon lamps. If he replaced them with Osram 8-c.p. lamps at a cost of 3s., the amount he could afford to pay per unit for current, without increasing the total cost of lighting, was no less than 11·8d., or, if he used Osram 14-c.p. lamps, 14·6d. It was quite clear, therefore, that there was ample margin for the total cost of electric lighting to be considerably cheapened, and for the stations still to get a satisfactory price for their current. This fact must in the long run be in favour of the stations. The authors did not want Parliament to raise the average price above 8d. per unit. They merely wished to be able to distribute the load fairly, viz., to raise the scale at one end and lower it at the other.

DISCUSSION IN LONDON.

Mr. Arthur Wright, who was called upon by the President to open the discussion, said he thought the answer to the question as to how metallic filament lamps would affect electric supply undertakings in this country depended entirely upon the men in charge and how it was managed. If it were left entirely to the wiring contractor, he thought that for two or three years they would have quite a bad time, but if the central station men took the matter up and insisted on people having more light for the same current, instead of less bill for the same light, it would be possible to counteract the effect of the use of these lamps, and it was quite possible to do it by judicious advertising. They should abandon such advertisements as "70 per cent. discount on your bills," and advertise "Three times as much light for the same bill." Of course, one important point in connection with competition with the gas companies was the great advantage which the latter had in the way of having no restrictions, or rules, or fire rules. A very great deal of harm had been done to the electrical industry in their being too ready to make the service absurdly safe. Returning to the effect of metallic filament lamps upon the electrical industry, he said that they must not overlook the enormously increased field for business which this new discovery made possible—a type of business which had always been considered beyond the range of commercial politics. So great was this field that he did not fear that the metallic filament lamp would do the supply business any harm; on the contrary, the consumption of current would be vastly increased because of this increased field. One point, perhaps, had not been sufficiently emphasised in the Paper. Most stations could supply a greater quantity of electrical energy at a very much lower cost than the average cost they were now supplying at, or, in other words, the increment charges of extending their business were nothing like the present average cost. Taking the case of Marylebone, which, perhaps, represented to an extreme degree many other undertakings in this country, the average cost was 4½d. per unit; they could double their output for an increase of 8 per cent. in the capital. If they doubled the output, the average cost would go down to 2¼d. per unit. It was therefore obvious that they must do everything to increase the output, and nothing in the way of restricting or making the business difficult must be entertained for a single moment. Another point to which he would like to draw attention was as to why most of them felt justified in charging less for power supply than lighting, although it might occur at the peak time. It was because of the great diversity among the motors, compared with lamps; 1,000 kw. of plant in a station could handle very much more kilowatts of motors at the peak than it could of lights, because the motors were not necessarily continuously on at the peak. The worse the load factor, the more the diversity factor helped. In the East-end of London he believed Mr. Tapper had found the diversity factor among motors was something like 4, whereas among lamps it was certainly never more than 1½. It was obvious from this that a very much lower rate could be charged for power, or for any supply not dependent upon the setting of the sun. With the exception of a few pumping installations, the average motor was as intermittently used as the tramway motor. The diversity factor among motors was tremendous compared with lamps, and it was on account of that difference that the standing charges were lower. There was another disadvantage that they were suffering from, viz., the high cost of house connection. At present it cost nearly as much per kw. to connect a house as it did to build a power station, and while they were taking all the trouble to reduce the cost of power-station capital, nothing up to now had been done to reduce the equally important cost of house connections. He hoped some day it would be possible to have one service per block, and some means of overhead supply to the different tenements, or outside tubes—anything to avoid this £10 or £9 per service, which was fatal to the supply of small consumers.

Mr. Hugo Hirst (General Electric Co.) said he had just sent to the secretary of the Institution a Paper in which he dealt rather exhaustively with the evolution of metallic filament lamps of various makes under various patents, and gave tests gained from experience by various station engineers in different countries, as well as many engineers in this country; he also in this Paper had dealt with certain questions such as transformers and other points raised by Messrs. Handcock & Dykes. He rather fancied that if he had had the opportunity of reading his Paper first, the conclusions of the authors in some respects would have been different. He did not wish to go into the details of his Paper that evening, but he merely mentioned the circumstances to explain why he did not describe some of the characteristics of these lamps as might have been expected. Dealing with a few points suggested by the authors, he objected to the statement that a 40-watt tungsten lamp gave 23 to 30 c.p.; this was somewhat unjust, as that lamp gave at least 32 to 35 c.p. The authors also gave some figures with regard to the life of this lamp. In practical experience the life of metallic filament lamps had surprised all makers of carbon lamps; it was considerably higher than the life of carbon lamps, and what the authors said about series running were conditions which, in connection with the tungsten lamp, did not exist at the present time. Tungsten lamps were now made and tested with such accuracy that they could be paired easily, and, after many hours, instead of throwing both of the lamps away as the authors suggested, it was possible to put a new lamp with the old one, and they would run perfectly well. There was a little trouble at one period, but that was due to an ordinary mistake in a factory, and since then there had been no trouble in actual use. There seemed to be a grievance that the lamp-maker was making too much money out of the metallic filament lamp. As a matter of fact, the greatest losers, in the first instance, were the lamp-makers themselves, for they had to depreciate their existing carbon filament lamp works, and had to go to such a considerable expenditure in the matter of patents and experience generally that it would take many years of good prices before this risk was covered. He therefore

Digitized by Google

thought the least central-station engineers—who would ultimately be able to benefit mostly from it—could do was to contribute somewhat to that capital expenditure if it was wanted for the benefit of the whole electrical industry, in the way of momentarily reduced takings from the supply of electrical energy. Taking the authors' figures of £6,000,000 per annum for the electric lighting industry, and £27,000,000 for the gas industry, he was quite sure that there was plenty of room for taking from the gas people another £6,000,000 or £7,000,000 by the use of metallic filament lamps, which would go entirely to the dividends of the central-station engineers. As a side issue, not without interest, he took the opportunity to betray an attempted conspiracy in this connection. When he realised twelve months ago that he was likely to control the sale of metallic filament lamps for some considerable time, he had the brilliant idea of asking 15 central-station engineers in London whether it would not be a good plan for them to take up the supply of metallic filament lamps to contractors, and the contractors, under their instructions, to introduce them in the first instance to gas consumers, so as to win them over to electric lighting, and thus to create a larger load before the present consumers could begin to reduce their load by substituting the more efficient lamps for their present ones. But the station engineers thought it was a plan for his own benefit, and the idea fell to the ground. At the same time, they need not now resort to panic measures; it might have a very detrimental effect if they were to alter things as regards electric lighting Bills by trying an experiment of the kind mentioned by the authors.

Mr. C. Bottomley Smith (Hove Electric Lighting Co.) said that without depreciating the very excellent system the authors proposed—namely the "contract demand" system, from his experience he thought it would be very unpopular from the consumer's point of view. He had had considerable experience of the minimum charge, and, having done away with that, and found the benefits of doing so, he thought the mystery of a "contract demand" and increasing consumers' account would have a very detrimental effect upon the industry. He could hardly agree with Mr. Arthur Wright as to the figure of £10 for house services; it would probably be done for much less than that. He thought the question of house service, however, was the great question that affected them if they hoped to double or triple the number of consumers so as to make up the loss of revenue of the consumers already connected.

Mr. W. R. Rawlings said it was not often that a Paper was read before the Institution of Electrical Engineers which called for a large number of electrical contractors to be present, and Mr. Wright had probably overlooked the fact that there were on this occasion a large number of contractors present when he made his statement with regard to them. More bad language was expressed over the Wright maximum demand indicator than anything else, within the contractor's hearing; if there was one thing more than another which upset the average consumer, it was the Wright indicator. In a certain installation of about 100 lamps which he (Mr. Rawlings) had fitted up, it mattered not what that consumer did, he always had to pay 7d. per unit. Another installation which had about 50 lamps was fitted by another contractor, and the consumer in that case managed to get through at about 4½d. His own consumer insisted that his installation was bad because he was paying 7d. whilst his friend was only paying 4½d. or 5d. He had never yet found a consumer who could understand the Wright maximum indicator. Another tariff system, introduced by Mr. Erskine, of the Kensington & Knightsbridge Electric Lighting Co., also gave the consumer great difficulty in understanding it; the consumer generally understood it at the end of the financial year, which was a little late. There were a number of installations in Kensington which had no less than three meters, three main switches, three double-pole fuses, and three sets of fuse boards, whilst one set of these mains, meters, and fuse boards would be sufficient to meet the whole requirements of each particular house. This triplicating of wires was only brought about by reason of the absurd system of charging. It was very nice from the contractor's point of view, but was a check on the development of the industry. Moreover, frequent inquiries were made for a kettle or food-warmer, but when the customer was told that he would have to pay 4½d. or 5d. per unit, or else have a separate set of wires and a meter, he absolutely refused to buy the piece of apparatus, and consequently the manufacturers suffered, and the contractors, who sold through them, suffered likewise. He was of opinion that the authors' system would encourage the use of such small apparatus, and he quoted from 24 specimen accounts from actual installations, which he had worked out on the author's system, and in which he found that the desirable consumer would pay less, and the bad consumer would pay more than at present. One point, however, he thought the authors had overlooked, and that was in making provision for special illumination, such as for parties and similar functions; there should be some method of charging a fee to cut out the automatic indicator on such occasions.

Mr. F. W. Long (Chief Electrical Engineer, Norwich Corporation) said that about eighteen months ago he went into the question of reductions to consumers, as he wanted to encourage the profitable consumers and also the use of radiators, &c. It occurred to him that if they could fix the standing cost in some definite way, such as on the assessment of the house, it would have many advantages. He took the consumptions of a number of houses and found that, on the average, a small private house used seven units per pound of assessment, and that this figure held equally for a larger private house. Thus it appeared that the rateable value was, on the average, a measure of the consumption, and it followed that the rateable value was also a measure of the average maximum demand of the house. He then found that if they were to charge 10 per cent. of the rateable value and one penny per unit, he would get the same income as they had hitherto. The charge actually fixed was 12 per cent. of the rateable value, and one penny per unit, and the system was put into force early in 1907, so that he had had fifteen months' experience of it. The advantages of the system were similar to those of the "contract demand" system, as only one pair of wires was necessary, there was no meter rent, and, further, a consumer knew within a little what his bills were likely to be for the year. At the beginning he had about 400 consumers on this system, but there were now about 800. At the end of twelve months he made a comparison. Taking 250 consumers and comparing them with the previous year, he found they had increased their consumption by 20 per cent., and, at the same time, the amount of revenue received from them was reduced to £328, or about 20 per cent. The average price per unit received was 3·1d. instead of 4½d. as before. He should point out that those who came first were the ones to get the greatest advantage out of the system, whilst in the case of those coming on afterwards there had not been nearly so much reduction. He found that this system gave very general satisfaction, and no one had suggested that it was not fair. People understood it, for they were used to rateable value as the basis for water, and they looked upon the system as quite reasonable. The result had been that in many cases people used the light all over the house instead of in a few rooms only. In addition, they had supplied over 100 radiators, which were a very useful load, as they were mostly used in bedrooms, and did not come very much on the peak. It was rather difficult for him to tell how much the maximum load had been affected by this system, as he had not got demand indicators in the houses. He had, however, compared the consumptions on Sunday evenings of December last year and the year before, and found that there was only about 1½ per cent. increase in the maximum load, whereas there was 8 per cent. increase in the consumption, so that it seemed he was getting a decidedly better load factor from private houses than before. He did not think the suggestion of "contract demand" was suitable for private houses as the basis of the assessment. Business premises, of course, had to be treated in a different way, and for these he had practically in a small way adopted the system suggested by the authors, viz., taking the demand of the place and charging at the rate of £10 per kw., *plus* one penny per unit. He did not think, however, that the "limit indicator" arrangement would be altogether satisfactory. The better plan was to include the maintenance of the lamps in the charge. By doing this and going round periodically they knew exactly how many lamps a consumer had. A fixed charge of one penny per unit and a variable charge per kw. gave considerable scope. They could charge £10 per kw. for ordinary lighting, but for such things as signs they could charge a lower rate, say, £5 per kw., and yet the current could all go through the same meter.

The discussion was adjourned until the 23rd inst.

Professor David Robertson (Bristol), in a written communication, suggested the following way of charging for electricity supply, as obviating the use of demand or limit indicators and special meters for different uses. A nominal load would be fixed by the consumer, as a rule with the assistance of the officials of the supply authority, and he would contract to pay a minimum sum proportional to this load each quarter, or each year. The meter would be adjusted so that it registered at the nominal rate when the consumer is taking his nominal load, at a higher rate with a larger load, and at a lower rate at lighter loads. The standing charges may be taken as proportional to the demand. The revolutions per unit should therefore follow a linear law with the load instead of being constant; the constant part would represent the running charges, and the remainder the standing charges, profit being included in one or both. With many types of meter, the writer says, there would be no difficulty in making an adjustment of this sort. In fact, he adds, they have naturally a law something like it, and have to be compensated for ordinary use. This method would take some cognisance of diversity factor, for no account would be taken of occasional heavy loads, whose diversity factor would probably be high, when determining the nominal load proper to any particular case.

DISCUSSION IN DUBLIN.

The Paper was also discussed in Dublin on Thursday.

Mr. R. N. Tweedy said that there was no doubt metallic filament lamps presented considerable economic possibilities to consumers on alternating-current circuits, although it was difficult to persuade consumers that it was possible to reduce their current bills some 60 per cent. by using them. For this the figures given by the authors would be useful. He did not think, however, that there would be any serious diminution in current

Digitized by Google

sold owing to the extended use of the new lamps on continuous-current systems, because it was necessary to use two lamps in series, and he thought that the time was still far distant when an 8-c.p. 200 or 250-volt lamp would be introduced. Yet he was strongly against a custom, apparently springing up in Dublin, of wiring new houses on the series system, as he considered that series running would only be a temporary expedient. Seeing that three times as many candle-power could now be obtained per kilowatt as formerly, electric lighting was really in no bad way, although there might be a temporary depression. Regarding the new tariff proposed by the authors, Mr. Tweedy considered that it made for simplicity. Engineers were altogether too honest; they tried to study equity among consumers too minutely, and consequently evolved elaborate tariffs understood by no one except the person who invented them.

Mr. G. F. Pilditch (Chief Electrical Engineer, Rathmines) considered that there was really no cause for alarm on the part of station engineers. He believed that private consumers really required more light, and stated that far more complaints were received due to insufficient light than to the amount charged. When the public found they could obtain more light for the same money they would go in for it rather than reduce their accounts. He considered the proposed new system of charging excellent from the supply authorities' point of view, but not from the consumers'. Consumers talked together, and if one consumer was supplied cheaper than another there was trouble.

Mr. C. Cummins said that, speaking as a contractor, he considered the advent of the Osram lamp was the salvation of electric lighting. No doubt incandescent gas lighting had educated the public to better light, and he believed that existing customers would now extend the use of electric light on their premises. Regarding the saving effected by the use of Osram lamps, he quoted the following cases, which were all quarterly accounts for December last using Osram lamps, and for the previous December quarter using carbon lamps, in most cases the light was greater than formerly :—

	Carbon.	Osram.	Saving.
(1).	£4 10 0	£2 10 0	£2 0 0
(2).	15 0 0	6 15 0	8 15 0
(3).	42 0 0	26 6 2	15 13 10

Mr. Cummins said that he did not believe in the use of 25-volt Osram lamps in conjunction with equalising transformers, as he thought that the smallest light unit used should not be less than 25 or 32 c.p. In his experience Osram lamps were not so fragile as stated. He had not obtained good results with tantalum lamps on alternating circuits, but had not yet gained experience with the new ones recommended for use on alternating-current circuits, in which he noticed that the filament was made in wave form, evidently with a view to allowing for expansion and contraction of the filament.

Mr. J. W. Boucher (Edison-Swan Co.) thought central station engineers, in raising the pressure of supply a few years ago, made a very great mistake. Lamps supplied for the lower voltage circuits were considerably more efficient. He entirely disagreed with previous speakers; people did not want more light; in fact, he had many inquiries from users as to how the light could be shaded down. The 100-volt metallic filament lamp was too bright altogether for private house lighting, although it might be useful for shops and lighting large areas. He considered the contract demand system of charging ridiculous. If he were in the habit of buying, say, three suits of clothes per annum from his tailor and it so happened he only required two suits one year, was his tailor to charge him half-price for the remaining suit he did not get?

Mr. W. Tatlow (Messrs. Egan & Tatlow) gave some useful figures comparing costs of gas and electric lighting. With electricity at 3½d. per unit and gas at 3s. 6d. per 1,000 cu. ft., a 55-watt Osram lamp cost for current per 1,000 hours 10s. 3d., and a gas mantle, consuming 4·5 cu. ft. per hour, 15s., while with a 55-watt Osram lamp the costs were equal. Mr. Tatlow believed that now more energy would be used than formerly, because, first, lights in cellars and so forth, burning long hours, would be converted to electric, thus improving the load factor; and, secondly, private plant users would now come on to the town mains, because their plant would be inefficiently loaded, and it would be cheaper for them to take town supply than to run their own plant. He found the life of Osram lamps to be high; in fact, he had some burning for over 2,000 hours, and they still appeared to be in good condition. One advantage of the metallic filament was that it gave a good light until it expired, whereas many carbon lamps lasted thousands of hours, and later in their life gave only a feeble glimmer, although often the consumer could not be persuaded to change them. Mr. Tatlow did not consider the maximum demand system a fair one, because demand made at times other than at peak time should not be charged at the higher rate; for that reason he preferred the two-rate meter system.

Mr. A. E. Porte agreed with other speakers that the public required more light, and would pay for it. What was lost in lighting would probably be made up in the more extended use of radiators, &c. He agreed with Mr. Tatlow that the two-rate meter was the best and most equitable system of charging.

Mr. W. J. Sowter (Chief Electrical Engineer, Bray) knew of very few consumers who actually understood the maximum demand system, and those who did gave the most trouble. He did not think consumers would take kindly to the "contract demand system," and if a change were necessary he thought it would be better in many cases to revert to the old contract system without meters. Such a course would, in his opinion, be quite feasible in the case of small private house consumers, for it is just in these cases, as the authors have pointed out, that the difficulties occur in making a profit. Mr. Sowter said the great difficulty he foresaw in making up for the depreciations caused by the use of Osram lamps was that of getting people to go to the expense of wiring their houses; some cheap system of free or deferred payment wiring was necessary, and at the same time the cost of mains and services must be reduced to as low a level as possible. It would be a great mistake to raise the price of current, as now was the time to prove the cheapness and advantages of electric light compared with gas.

The Paper will also be discussed at Glasgow on May 12th.

OPENING OF THE ALDWYCH-EMBANKMENT L.C.C. TRAMWAY SUBWAY

THE formal inauguration of the extension of the tramway subway under Kingsway, from Aldwych to the Embankment, which was described in illustrated articles in Electrical Engineering March 5th, page 343, and April 9th, page 553, took place last Friday, when the linking up of the northern and southern systems of the London County Council tramways became an accomplished fact. A party of over 150 persons, including representatives of the Board of Trade and the Local Government Board, the Mayors and other officials of several of the London Boroughs, Members of Parliament, well-known engineers and tramway men, and a number of members of the Council, including Sir Alexander Kennedy and Sir Clifton Robinson, assembled at the L.C.C. Training College in Southampton Row, where they were received by Mr. R. A. Robinson, Chairman of the Council, and Mr. W. Whitaker Thomson, Vice-Chairman of the Council and Chairman of the Highways Committee. Before calling on the Chairman to proceed to the opening of the subway, Mr. Whitaker Thomson made a few remarks on the work which has been accomplished. The Council's tramway system now carried something like a million passengers a day, and the completion of the subway, the first portion of which was opened in February, 1905, would form the connecting link between the fifty miles of the northern system and the sixty-six of the southern system. He referred to some features of the construction of the subway, mentioning more particularly the problems to be faced under Wellington Street, and paid high tribute to the work of the Council's engineers and the Works Department, who had carried out the whole of the construction. In spite of such difficulties as there had been, the work had been completed within a week of the appointed time.

The party then proceeded to the Holborn subway station and boarded the five special cars which were waiting. The procession, with Mr. A. L. C. Fell, Chief Officer of Tramways, in charge of the first car, then proceeded through the subway, passing out on to the Embankment, and continued their route over Westminster Bridge to Camberwell. A return was then made, and the cars once more went through the subway and proceeded to Islington, and then back to the London Day Training College, where refreshment was partaken of.

Later in the afternoon a regular service of cars was started. Two through routes are now in operation, one from Highbury to the Tower Bridge, the fare for the whole journey being as low as 3d., and another from Highbury to Kennington.

Antwerp Docks Electric Cranes.—A Consular Report states that at the end of the present year, 1908, the installations of cranes at the Port of Antwerp will include one 120-ton electric sheer at the Kattendyk Dock, one 50-ton electric crane, and 80 electric cranes of from 1½ to 2 tons.

Blackpool & Fleetwood Tramway Co.'s Rate.—On Friday before Mr. Justice Ridley and Mr. Justice Darling, sitting as a Divisional Court in the King's Bench Division, Mr. Leslie Scott applied for a rule for an order in the nature of a mandamus that the Justices of Lancashire should issue their distress warrant for the payment of rates by the Blackpool and Fleetwood Tramway Co. Counsel said that on the application of the distress warrant to the magistrates questions of law and fact were gone into which ought only to have been gone into on appeal to Quarter Sessions. Their lordships would remember that the powers of the magistrates on an application to enforce payment of rates were very limited. Proceedings had been taken by way of a special case, but they came to nothing, and counsel now thought this was the proper procedure. Their lordships granted the rule.

ACCOUNTS OF THE NORTH METROPOLITAN ELECTRIC POWER SUPPLY COMPANY

IN view of the very rapid increase of the business which is being done by the North Metropolitan Electric Power Supply Co., which is now one of the most advanced power companies in the country, it is of some interest to examine the published accounts of the company as an example of costs of supply on a large scale. Before proceeding to analyse the figures, the conditions under which the supply is being carried out should be briefly considered.

The company, as is well known, owns two main generating stations at Brimsdown and Willesden respectively, from which an extra high-pressure three-phase supply is given to a number of sub-stations distributed about the area of supply. By this means a bulk supply is given partly through the North Metropolitan Power Distribution Co. to several districts, including Willesden, Stoke Newington, Enfield, Edmonton, Tottenham, &c. Current is also supplied to the Metropolitan Electric Tramways and direct to several large power consumers, including the works of the Edison-Swan Co. at Ponder's End, and others. About 70 miles of E.H.T. mains are in use. Considerable further extensions are in progress.

It is unfortunately impossible to give the generating costs of the two stations independently, as they are not separated in the accounts, nor are particulars of the units generated at each station and used in conversion given.

The total number of units sold during the year ended December 31st, 1907, amounted to 11,183,316, which, compared with the figure of 7,999,367 for the previous year, shows an increase of approximately 40 per cent. Particulars of the maximum demand, however, are not included, so that it is impossible to work out the load-factor. The following table gives an analysis of the revenue account showing the costs per unit sold for the whole undertaking:—

	Total. £.	Pence per unit sold.
Generating costs—		
Coal	18,027	0·387
Oil, waste, water, stores, &c.	1,075	0·023
Salaries and wages	4,538	0·097
Repairs and maintenance	2,963	0·064
Total generating costs	**26,603**	**0·571**
Distributing costs—		
Salaries and wages	1,747	0·037
Repairs and maintenance—Mains	836	0·018
,, ,, Substations, &c.	225	0·005
,, ,, Sundries	267	0·006
Total works costs	**3,075**	**0·066**
Management expenses, &c.—		
Rent, rates and taxes	3,487	0·075
Salaries, fees and establishment charges	2,448	0·052
Law and other charges (including insurance)	639	0·014
Depreciation	4,000	0·087
Total, excluding capital charges, £40,252		**0·865**

It will be seen that the figures are considerably lower than those obtaining in the majority of undertakings.

The total receipts (including £58,749 for sale of current) amounted to £59,373. Of the balance thus given, interest on mortgage debentures, loans, &c., absorbed £6,993, and £840 was paid under agreement to the Stoke Newington Council, so that with the addition of £864 received by interest and dividends, the final net balance (including £520 from last account) was £12,672.

A summary of the capital expenditure up to December 31st, 1907, is given below:—

	£	s.	d.
To Lands, &c.	8,235	1	4
To Buildings	93,052	4	5
To Machinery	162,387	18	8
To Accumulators	6,878	6	5
To Mains	99,856	8	6
To Meters	132	7	2
To Transformers, Motors, &c.	36,563	0	8
To Electrical Instruments, &c.	956	18	4
To Public Lamps	221	0	5
To Ballast Burning	180	17	3
To Water Service	158	5	1
To Motor Car	306	7	8
To Sundry Plant	174	17	3
To Brimsdown Dock	1,494	12	5
To Furniture	521	4	0
Total Expenditure on Works	£411,119	9	7
To Cost of Special Acts and Orders	20,223	4	10
To Special Items	2,478	4	11
Total Expenditure	£433,820	19	4

Wireless Telegraphy and Telephony.—A Consular report from Christiania refers to a new system of wireless telephony invented by Professor Birkeland, of Christiania, but no technical details are given. It is stated that on one of the University buildings three masts were erected about six months ago, and the Professor has succeeded in carrying on conversations, with excellent results, with another station at Frogua, about two kiloms. distant.

The following report on the wireless telegraphy service between Trinidad and Tobago, which has now been in operation for 2½ years, appears in the *Colonial Officers' Journal* for April. The power now used is so small that there is little danger of breakdown, and the plant is in duplicate. The more powerful but less economical set is run about once a month to keep it in order. The temporary posts erected in the first instance have started to rot, and hard wood butts will have to be fixed soon if the present stations are to be permanent. Experiments were made with the Lodge-Muirhead most recent arrangement of raising the lower aerial capacity from the ground. It was evident that this is an improvement leading to less power being required, and greater freedom of interference from both atmospheric disturbances and signals from other stations. Instructions have been given to the chief wireless operator to carry this improvement out at a cost not exceeding £20, from the working estimate of this financial year. The operators have made several experimental receiving transformers, and they are now able to exchange satisfactory signals under most conditions. From trials made whilst two or more American battleships were signalling at the same time, it was evident that under ordinary conditions the station at North Post could be arranged to receive by sound two sets of signals at the same time, with wave-lengths differing 10 per cent. or even less. The sound detectors recently installed work satisfactorily. It was only after receiving with these that the writer of the report could advocate the use of wireless stations in preference to the telephone for outlying districts.

Private Telephone Lines.—The hearing was resumed on Tuesday, April 7th, of the appeal of the National Telephone Co. against the decision of Mr. Justice Swinfen Eady, with regard to the monopoly of the Postmaster-General concerning private lines. We reported the previous hearing in our issue for March 19th, p. 432. The appeal was opened on the 11th ult., and it stood over for the purpose of enabling the defendants to consider what their position would be if the Court held that upon the true construction of the licence the royalties in dispute were payable. Sir Robert Finlay, K.C., on behalf of the appellant company, now contended that though the terms of the licence were absolutely general and so wide as to include what the Attorney-General admitted to be private telegrams not requiring a licence, the Act made it abundantly clear that the licence was only taken out for those things for which a licence was required, and of which the Postmaster-General had a monopoly. His learned friends could not successfully contend that those general terms amounted to any estoppal at all. The Attorney-General, on behalf of the Postmaster-General, said the parties had always treated an "A to B" line as within the licence. If the licence were treated as the company suggested, the bargain would be one which neither of the parties intended when it was made, and there was, therefore, a strong case of estoppal. Sir R. Finlay said the company had paid royalties on A to B lines up to March, '97, but since then they had refused to pay, and that had led to litigation. If the Postmaster-General's contention with regard to fire alarms was right, every electric door bell would be an infringement of his monopoly. Their lordships reserved judgment.

THE MOTOR HIRE DEPARTMENT OF THE BIRMINGHAM CORPORATION

IT has always been a trouble to the central station engineer that such large proportions of his plant should have to stand idle for so many hours out of the twenty-four, and although the need of a load during daylight hours has been obvious ever since the commencement of public supply stations, yet it is only within the last five years that any great improvement has appeared in the load factor of lighting stations, due to the sale of current for power purposes. The most promising class from which to expect a demand for electric power are the proprietors of small works and factories, as the larger concerns generally have their own electrical generating plant, but the smaller proprietors are usually unable or unwilling, until convinced of its advantages by trial, to afford the initial expense of installing electric motors.

To meet this difficulty a Motor Hire Department has been started by many of the supply authorities, and we are enabled, through the courtesy of Mr. Chattock, the City Electrical Engineer, to give some particulars of the Motor Hiring Department of the Birmingham Corporation. It was decided some eighteen months ago to form such a department, and although it is too early yet to give reliable figures as to the financial results, still, there is no doubt as to the department proving a success. Whereas in the autumn of 1906 there were no motors out on hire, there are at the present time a total of 280 motors, aggregating 1,800 h.p., and these figures are steadily increasing.

The department is divided into two branches, which deal with: (1) Testing; (2) installation and inspection. The former is responsible for the testing and repair of all motors and their switchgear. Every motor is thoroughly tested on its arrival from the makers before being put into stock. The tests comprise a full load run for six hours, at the end of which time temperatures are taken, and if the temperature rise exceeds 85° F., the motor is rejected. There is also a limit to the rise in speed, which must not exceed 5 per cent. at the end of the above run. The motor is further tested at 25 per cent. overload for one hour. The insulation resistance is then taken with a 500-volt megger, but the motors are not subjected to any high-voltage test. It is almost always found possible to test motors in pairs by the Hopkinson method. The pulley on the generator is a little smaller than that used on the motor, the motor is run at its normal speed, and the generator slightly above speed, the generator field being separately excited and a rheostat placed in circuit. The machine which is motoring thus approximates to normal working conditions. In the event of a Hopkinson test not being possible, an artificial water load is employed. If a motor has been in stock for more than a week or two, the practice is to run it on full load for a short period, and take the insulation resistance.

A moderate stock is kept of all sizes of motors from ½ to 50 h.p., and the stock list is sent at regular intervals to the makers of the motors for their guidance in keeping up their own stock, as they are required by their contract to deliver additional batches of motors within two days of receipt of a requisition for same. In this way the likelihood of a motor not being forthcoming on receipt of an urgent demand from the installation branch, is extremely remote.

Motors are purchased in the following way:—Tenders are asked for to a specification drawn up by the department, and advertised in the electrical papers, and tests are carried out on those motors which are in accordance with the specification and seem generally satisfactory. The Electric Supply Committee then decide upon the placing of a contract for each size of motor required in accordance with results of such tests. The original contract, which was divided between two or three firms, was made for two years, in order that continuity of the make of the motors may be obtained for as long a period as possible.

The installation branch is responsible for the erection and connecting up of the motors and starters on foundations which the customer is required to provide. The Corporation does not undertake the wiring work in connection with motors, as this is left to contractors, but it furnishes expert advice to the customer as to the size of motor required and best method of drive. All motors are regularly inspected at least once a month, but in certain cases, where conditions of drive are bad, or for other special reasons, a much more frequent inspection is made.

The system of supply in Birmingham is three-wire D.C., with a pressure of 410 volts between the outers. But in outlying districts three-phase current at 5,000 volts, and a periodicity of 25 complete cycles per second is supplied. At present the Hire Department deals only with D.C. motors. All the motors used are of the shunt-wound, semi-enclosed type. Up to 3 h.p. the motors are wound for 220 volts, but above this size the winding is for 440 volts. Each size of motor runs at a standard speed, and is provided with a standard pulley: although there are a few direct-coupled and geared motors running, yet it is desired, as far as possible, to keep to belt drives in order to simplify installation and repairs. A word should be said with regard to the switchgear employed. The practice is to terminate service mains in a combined D.P. switch and fuse in iron case, the fuses being of the cartridge type. From this point the customer is responsible for the wiring up to the motor control gear, which is supplied with the motor, and which consists of a combined D.P. switch and fuse in iron case, and a motor starter fitted with the usual no-volts and overload release, also in iron case.

Birmingham contains an unusual number of small shops and factories of all sorts, and the purposes for which motors are required are very varied. It will be of interest to mention a few examples which have come under our notice. At a certain tube works a 50-h.p. motor drives eight tube draw-benches, each capable of drawing 2in. copper tubes, and also drives a few small lathes. This motor would be too small for the work were it not fitted with a flywheel to cope with large instantaneous demands for power. A motor of 30 h.p. drives a large circular saw, a band saw, and a small planing machine. In the jewellery trade a considerable number of motors are used, the operation requiring most power being that of polishing, which is carried out by wheels locally termed "grease mops." A 10-h.p. motor is employed for the driving of nine such double-ended wheels, although the demand from one wheel may at times amount to 4 h.p. Several bakeries are electrically driven, the usual size of motor installed for dough mixers being 3 h.p.

Butchers are finding the convenience of electric driving for their meat-chopping and sausage-making machines; 5 h.p. usually suffices for this purpose. A small laundry takes 3 h.p. to drive a washing and drying machine, and one of larger size demands 10 h.p. for two washing and drying machines and three ironing machines. The majority of the motors on hire are used to drive lathes, and similar machines in small fitting and brass finishing shops, of which there are a great

Digitized by Google

number in Birmingham, group driving being the usual method adopted.

Few serious difficulties have so far been encountered. Perhaps the chief cause of all the troubles that have occurred has been the fact that motor hirers will not treat the motors as they would if they were their own property; thus seized bearings have been found due to the oil well being quite dry, and this, in spite of the fact that printed instructions on such points as oiling and cleanliness are sent out with every motor. It is also occasionally found that the consumer in filling up the oil wells has flooded these, and oil has got into the interior of the motor. In order to prevent this happening, and also to do away with the inconvenience to the consumer, who has to purchase oil from the Corporation, and who is responsible for keeping the bearings properly oiled, it is proposed to adopt ball bearings on motors in future. These can be periodically filled with grease by the department's inspectors, and will be very much more cleanly and suitable for the purpose, besides giving slightly better efficiency.

A pamphlet is issued by the Corporation Electric Supply Department, which gives conditions as to the hire of motors, together with the scale of charges and particulars of motors supplied on hire. The pamphlet also gives directions to be observed to ensure the safe and satisfactory working of electric motors; the advantage gained by the use of motors, and the advantage of taking motors on hire terms. A draft of agreement for hire of motors is given at the end of the pamphlet. The chief provisions contained in this agreement are that:—(1) The specified rent of the motor and starting gear shall be payable quarterly in advance; (2) the hirer shall keep the motor and gear in good and clean order, save reasonable wear and tear, and shall carefully attend to the working instructions issued by the Corporation; and, further, shall not do or suffer anything to be done whereby the motor may be distrained; (3) the hirer shall make good any damage incurred through improper use, fire, accident, stress of weather, or any other unusual cause; (4) the Corporation be allowed access to the motor at all reasonable times for inspection or repair; (5) if the hirer fails to keep the conditions of the agreement the Corporation may remove the motor; (6) the hire may be determined at any time by either party giving one quarter's notice.

The annual rental charged for the various sizes of motors varies from £2 10s. for ½ h.p.-motor, up to £26 for one of 50 h.p. This rent includes the use of the motor, starting switch, main D.P. switch, and cut-outs. There is a separate schedule of charges for conveying and fixing motors, ranging from 7s. 6d. up to £1 10s. for motors of from ½ h.p. up to 50 h.p. The Corporation stipulate that oil and carbon brushes must be purchased from them at specified prices; the hirer is, however, not allowed to fit new brushes himself, but this is done by the Corporation.

The cost of electrical energy for hire purposes is on a sliding scale. For the first 300 units per quarter the charge is 2d. per unit; for any further quantity used in the same quarter up to 3,000 units, the charge is 1½d. The charge decreases with the increase in consumption until consumers of 180,000 to 250,000 units per quarter obtain their energy at 1·07d. per unit.

Considering its brief existence, the Motor Hire Department of the Birmingham Corporation may be said to have done very creditably, and when we remember Mr. Chattock's past record at Bradford, where, if we are not mistaken, he had motors on hire aggregating over 5,000 h.p., so far back as 1902, we have no hesitation whatever in prophesying a very successful future for this department.

Aron Meter. The Board of Trade has approved the Aron alternating-current prepayment motor meter.

MANUFACTURE OF METALLIC FILAMENTS

The new "Z" Lamp

DR. CLAYTON H. SHARP gave an address recently before the American Electrochemical Society, in which he dealt with the various methods of manufacture which are employed for tungsten and similar filaments. The following abstract from the *Electrical World* gives a *résumé* of the principal methods, including that employed in the new "Z" lamp.

There are certain main difficulties in producing a filament from a material like tungsten due to the fact that the tungsten is not ductile and unites readily with oxygen or carbon. Hence it is the practice to produce filaments from tungsten in the form of a very fine powder, which is held together by some sort of binder which can be removed after the filament has been squirted; this removal must leave the filament free from oxygen and carbon. A number of processes have been described. The first to appear was that of Kuzel, in which a collodial solution of tungsten is formed by making an arc between tungsten terminals under water. This solution when of the proper consistency is squirted into filaments which consist entirely of pure tungsten and water. When the water has been driven out, the tungsten particles can be sintered together by heating the filament by means of the electric current in an atmosphere containing no oxygen. In Welsbach's process, an organic binder is used to make a paste which can be squirted through a die. The binder is removed by heating in an atmosphere which will oxidise the carbon and which contains at the same time sufficient hydrogen to reduce any tungsten which may have been oxydised. For the Just-Hanaman process, a very fine filament of carbon is heated in an atmosphere of chloride of tungsten and hydrogen. This results in a deposit of tungsten upon the filament or a substitution of tungsten for carbon. The carbon must afterward be removed by some such process as indicated above. In the "Z" process, a binder of collodion is used which can be made to burn itself out entirely. It has been found possible also to use binders of paraffine, which material can be removed simply by heat; or a slow melting metallic alloy may be used as a binder, the foreign metals being driven off by heat. An account was given of the results of a manufacturer's test on 15 series tungsten lamps, in which the average candle-power did not change during 2,135 hours of burning. Of these lamps, five survived at the end of the test, and only three had actually burned out.

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the Institution on Thursday:—*Associate Members:* J. H. Bolam, G. W. Cole, A. W. Mandling, H. E.. Morrow, G. D. Nelson, J. R. Norris, Lieut. A. Rice, R.N., S. Richards, C. C. Skeates. *Students:* G. J. Duckett, A. N. Haworth, V. M. Levy, C. A. Martin, T. Y. Porter, P. B. Smith.

Large Curtis Exhaust Steam Turbine—We are informed that the British Thomson-Houston Co. have received an order from the Tyneside Electrical Development Co. for an exhaust steam turbo-generator having an output of 1,500 K.V.A. at 2.875 volts 40 cycles, when running at a speed of 2,400 r.p.m. The turbine will be of the standard Curtis two-stage type, and will be direct-coupled to a three-phase 40 cycle alternator. The steam for this turbine will be supplied from the works of the Teesbridge Iron Co., at atmospheric pressure, and will be condensed by surface condensing plant supplied by the Mirrlees Watson Co. The condensed steam will be returned to the Teesbridge Co. Provision has been made so that should the turbine not be running at any time it can be isolated from the condensing plant, and the condensed steam still utilised for the boiler feed of the Teesbridge Iron Co. The turbine and the generator will be capable of an overload of 1,800 K.V.A. The plant had been so arranged that the necessity for the usual foundations are avoided, the condenser being on the same floor level as the turbine itself. The air and circulating pumps will be driven by three-phase 440-volt 40-cycle B.T.H. motors. The sluice valve between condensing plant and turbine will also be motor-operated.

THE SILVERTOWN ELECTRIC CAR

In view of the popularity of the quiet and smooth running electric car for town work, and other purposes where a limited radius of action is of no consequence and great speed is not required, it is not surprising that a firm with the wide electrical experience of the India Rubber, Gutta Percha, and Telegraph Works

Fig. 1.—Silvertown Electric Car.

Co. should have turned their attention to this class of work. The company have been experimenting both in the laboratory and on the road for some time, and one form of "Silvertown" electric carriage was seen in the Olympia Exhibition of 1905. The result of this work has been the production of the perfected car illustrated in this article, which has been brought out as a standard type of vehicle suitable for town work.

The principal points of interest in the design are the fact that both the front and rear wheels are driven and the design of the controller. The advantages of four-wheel drive are the diminution of liability to side-slip to an appreciable extent, and the better utilisation of the weight of the vehicle for adhesion by dividing the tractive force, thus also diminishing the liability to skidding as compared with back-wheel or front-wheel drive alone. A general view of a complete Silvertown car, with a specially designed limousine body, is given in Fig. 1, and Fig. 2 is an elevation showing the arrangement of the chassis.

The frame is of pressed steel of ample depth and thickness, inswept at the front to allow of a good steering lock, and specially stiffened at the back cross-member to support the transverse spring without twisting. Each front dumb iron forms one piece with the side of the frame to which it is electrically welded. The springs are long, although fairly stiff, in order to give as much comfort as possible in travelling over rough roads, and have large eyes in which are fitted renewable grease-retaining bushes.

The two motors are mounted one on each axle casing, thus giving the four-wheel drive. They are of the four-pole type without interpoles, and are totally enclosed so as to be perfectly dust- and damp-proof, but are fitted with quickly removable covers over the commutators, rendering the inspection and adjustment of the brushes an easy matter. The totally enclosed motors, when tested in the shop with 80 volts, 25 amperes at 1,060 revolutions per minute, gave a temperature rise of 70° F. at the end of one hour's run. On 30- to 40-mile test runs on the road, with average alteration in speeds, the rise does not, of course, amount to as much, owing to the much better cooling conditions prevailing. The motors are capable of working at 50 per cent. overload for a considerable time, and for a short time at double their ordinary load without any injury, and are so arranged that should either motor get damaged, the carriage can be run on the other alone. Details of the design of the motors are shown in Fig. 3. The armatures are mounted on ball bearings, and can be easily removed. The drive is transmitted from the armature by means of spur gearing, and both the pinion and gear-wheel are case-hardened. The latter is mounted on the outside of the differential gear-box, which also runs on ball bearings. The driving shafts are of nickel steel, turned all over, and transmit the drive to the

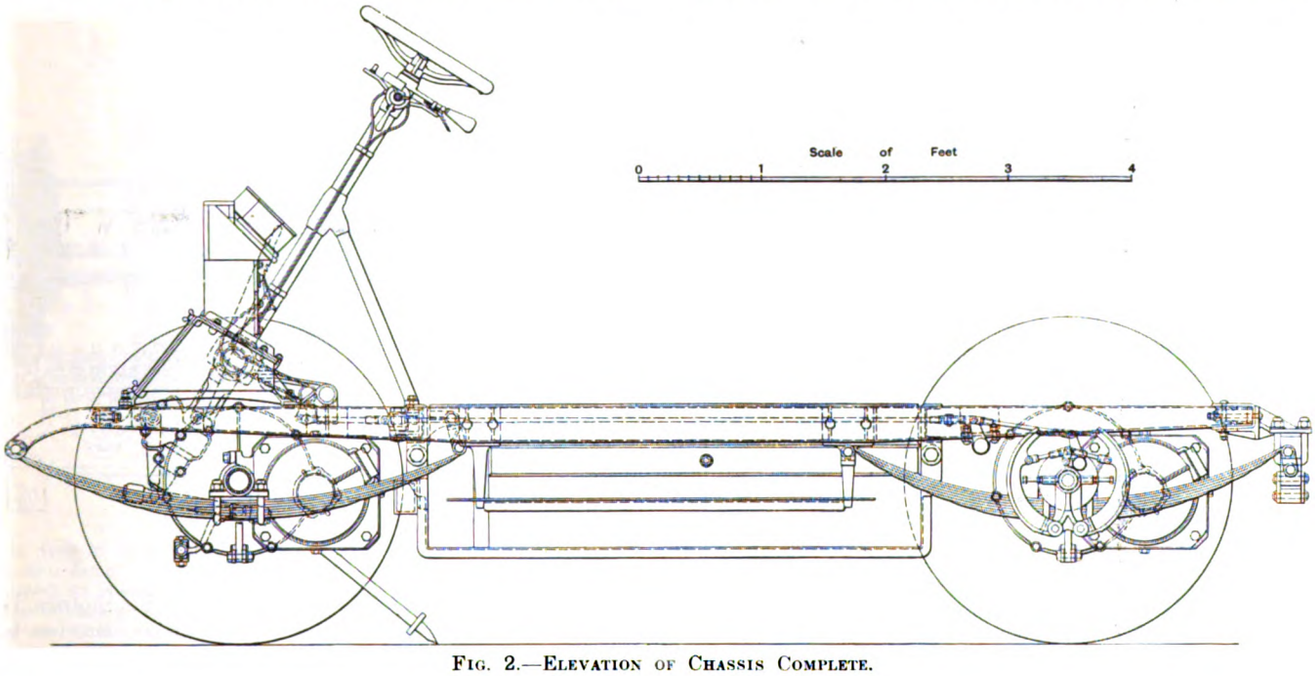

Fig. 2.—Elevation of Chassis Complete.

Digitized by Google

hubs of the road-wheels through sliding clutches. Each road-wheel is fitted with a compound ball-bearing, containing two journal bearings and one double-thrust bearing. The whole of the running gear is completely enclosed by the axle casings.

The arrangement of the motor and gear on the front axle is similar to that of the back axle, except that a special form of universal joint is provided at each end of the driving shaft at the same centre as the steering pivot, thus allowing free steering whilst at the same time transmitting the drive. This universal joint is carefully protected by dust- and wet-proof casings.

The controller is contained in a casing at the base of the dashboard, and is operated by a lever on the steering column. Details of its construction are given in Fig. 4. It will be seen that the main drum is entirely without wood, and is built up of special shaped segments. These are made from phosphor-bronze castings, and are mounted on an ebonite-covered steel spindle; the contact brushes, which are made of wrought copper, are carefully fitted to the drum of the controller to ensure a good bearing surface. Each brush can be quickly removed for inspection. The current is not broken on the drum, but automatically by a quick-break switch with carbon contact, thus preventing burning of the segments. This switch is also independently operated by the brake pedal before any braking can take place, and is held open by a cam when the brake pedal is released until the controller handle is brought back to the neutral position. The cam is then released and the switch made again as the controller handle is moved to the notch required. It is thus impossible to restart the car inadvertently by releasing the brake pedal.

The safety plug, which the driver should always take with him if he gets off the car, as its removal prevents anyone tampering with the car, cannot be placed in position or removed unless the switch is open. The same plug has to be used, in another position, if the battery is being charged whilst on the car. The wiring is so arranged that the controller circuit is entirely cut out, so that any accidental moving of the controller handle when the charging is in progress, does not do any damage.

The controller has as many as thirteen positions in all, giving six forward speeds, four reverse speeds, and three braking positions. In the first three forward speeds or starting positions the motors are in series with varying amounts of resistance in circuit, while the resistance is cut out in the fourth or series running position. In the next position the motor armatures are placed in parallel, but the fields remain in series, and the highest speed is obtained with the motors in full parallel. The four reverse positions are similar to the series forward steps, except that the armature connections are reversed. In the first braking position the motors are in series with the armatures reversed, the battery circuit cut out, and the whole of the resistance in closed circuit, while the two more powerful braking positions are obtained by cutting out parts of the resistance. It will thus be seen that there are, in effect, three forward running steps and one reverse, as the resistance steps are only provided to produce a

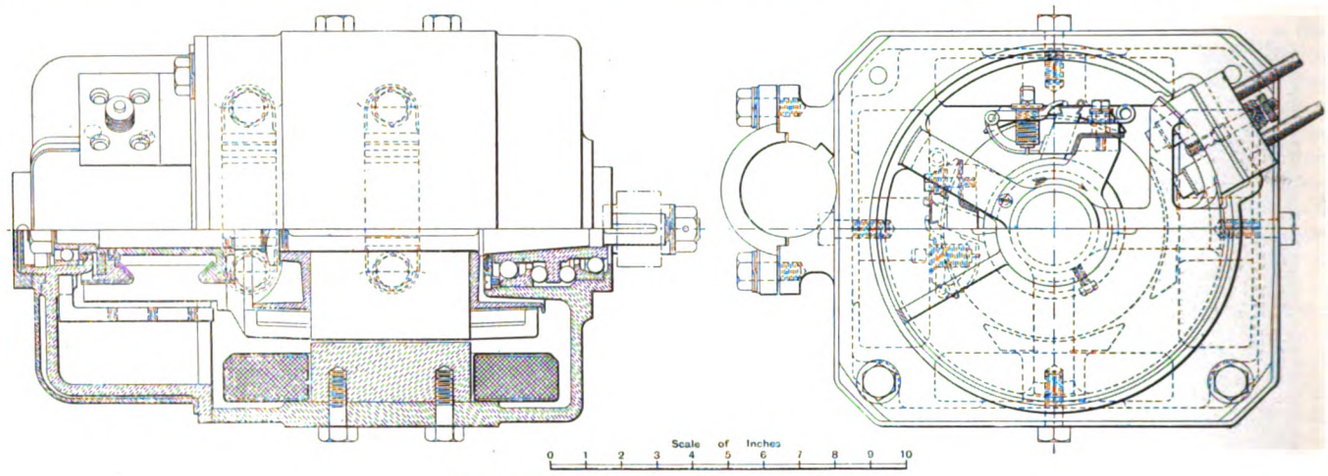

Fig. 3.—Elevation and Section of Motor.

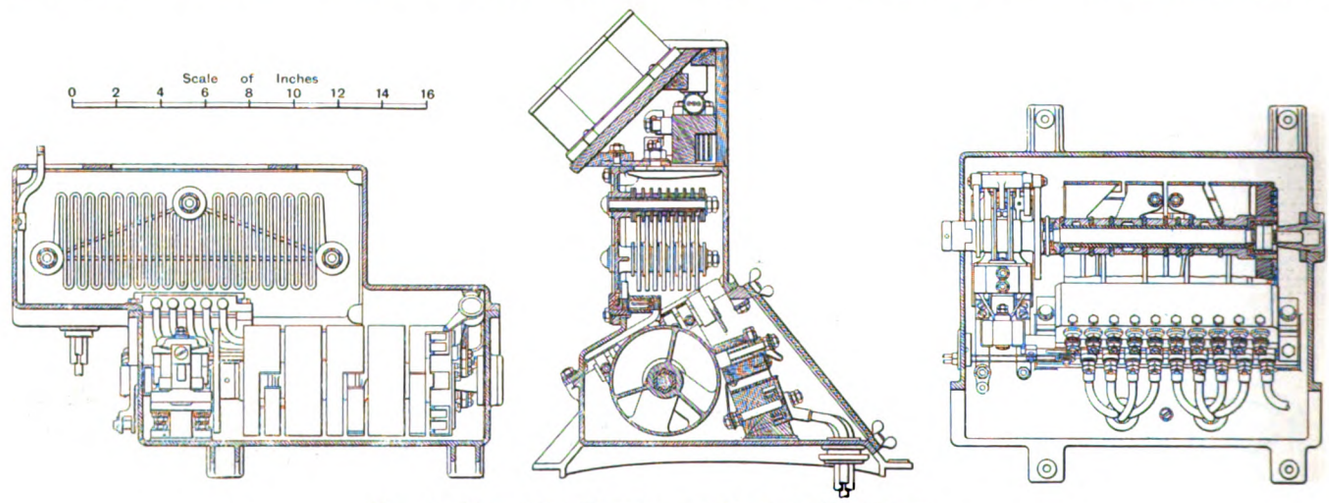

Fig. 4.—Elevation, Section, and Plan of Controller.

Digitized by Google

graduated start, and are not intended for running on. The resistance has, however, been so designed that the first three positions can safely be used as running positions when absolutely necessary in following traffic, although this should, of course, be avoided from reasons of economy. The resistance is of the grid type, as shown in Fig. 4, in the same case as the controller. This case is easily removable from the car if required, and has mounted on the top of it a combined ammeter and voltmeter.

The only mechanical brakes are those on the rear wheels. These are of the internal expanding metal type, and are double-acting. The phosphor-bronze brake-shoes work on the inside of a steel drum, which is rigidly fixed to the hub of each rear wheel, and are well protected by an aluminium cover from all wet and dirt. The brake will hold the carriage equally well from running backward or forward. All parts of the brake gear are made adjustable, and a notched lever is fitted to hold the brake pedal in any desired position.

The steering gear, combined with the bevel wheels for actuating the controller drum, is contained in a steel case which is made dirt-proof, and is securely fixed to the frame of the car. The steering is of the irreversible type, and the connecting rod is provided with cushion springs and adjustable ball-joints to take up any shock from the road. All parts are made adjustable, the worm segment being held in eccentric bearings. The radius rods are made out of solid forgings, and are securely fixed to the pivot axles.

The battery is contained in one crate slung underneath the frame, and can be easily detached and replaced by a freshly-charged one. The battery on the particular car illustrated is composed of 44 E.P.S. cells of a capacity of about 130 ampere hours, and weighs, including crate, 14 cwt. On good roads a single charge will propel the vehicle about 40 miles without unduly discharging the battery. The total weight of the car with the form of body illustrated is 37 cwt. complete with battery.

A NEW ARC LAMP COUPLING

IN the ordinary types of arc lamp couplings fitted with strain release it is essential that the user should hoist the lamp as far as possible, and then lower back slightly on the winch, thus bringing a locking gear into action, and releasing the strain from the suspension rope. To subsequently lower the lamp it must again be hoisted higher than when originally locking same in order to release the locking catches, and it can then be lowered down. To ensure safety and ease in working it is essential that these upward and downward movements of the lamp should be definitely limited by stops in the coupling, so that the locking and release of the lamp does not depend on the skill or trustworthiness of the trimmer.

In the case of couplings which do not comply with these requirements, and in which the definite stop for the locking position is wanting, the trimmer hoists the lamp to as far as he thinks necessary, and then lowers slightly to test whether the lamp is locked, and the strain therefore on the hoisting rope released. Several attempts may be necessary before he is able to lock the lamp securely, and thus there is a great loss of time and some risk that in hoisting the lamp too high the locking device has been set to the unlocking position, and therefore the

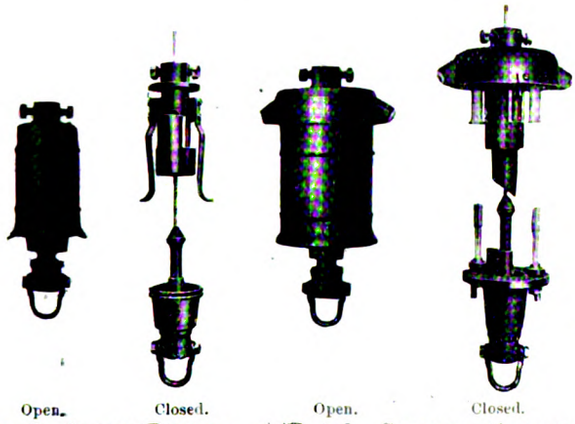

FIG. 1.—STRAIN RELEASE.

FIG. 2.—COMBINED COUPLING AND STRAIN RELEASE.

lamp is free to fall. The accompanying illustrations represent a new arc lamp coupling which the Union Electric Co. have introduced to obviate these disadvantages. It is provided with a strain releasing device in which all the movements requisite to lock or release the lamp are definitely limited by fixed stops. The lamp trimmer therefore hoists the lamp until he feels that it is against a stop, then lowers it slightly, when the lamp is securely locked, and the strain on the suspension rope released. To lower the lamp, he again hoists until he feels the stop and then lowers. The locking action is controlled by an ingenious arrangement of metal balls used in sets of two, one forming the top, and the other the bottom stop.

The mechanism can be supplied either simply as a strain release, as shown in Fig. 1, or as a combined arc lamp coupling with strain release, in which case the circuit contacts are made with massive pins, as shown in Fig 2. All these illustrations are to the same scale, so that the difference in size of the two arrangements is clearly visible. The sectional drawings in Fig. 3 show the action of the locking arrangement. The rope clamp supports a guide tube fitted with a projecting boss and a sleeve free to turn on the guide tube, and carries the two contact pins. On hoisting the lamp, the boss enters tube attached to the lamp bracket or other fixture. This tube is fitted with two longitudinal slots surrounded by a sleeve, free to move, and takes a bearing on a screw (not shown, which forms a stop). In this sleeve on each side are two depressions, which allow entry of balls and from the longitudinal slots of tube.

On hoisting up the lamp the boss enters the tube, and pushes the

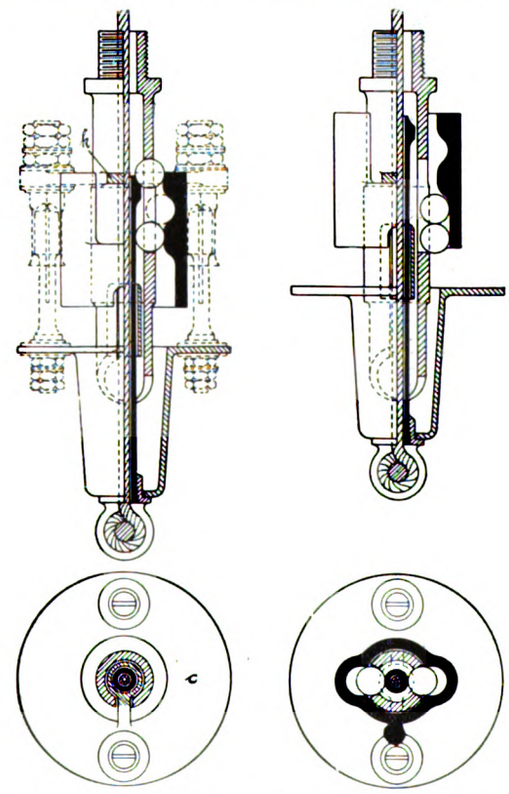

FIG. 3.—DETAIL OF COUPLING SHOWING BALL-LOCKING GEAR.

lower set of balls into the depressions, thus pushing the upper set upwards, so that, having passed the lower set, it meets the upper set, which thus form a fixed stop, as shown in the left-hand portion of the diagram. If the winch is now turned backwards, then the boss rests on the lower set of balls, and the hoisting rope is no longer under strain. The upper set also fall back into the depressions. During these movements the contact pins for the circuit have entered the corresponding bushes; to ensure correct polarity, the central tube is suitably pointed and slotted, and a guide pin on the lower sleeve engages therewith.

To release the lamp, the winch is again wound upwards, thus

Digitized by Google

raising the boss and permitting the balls to drop into the position shown in the right-hand part of Fig. 3. In this position the sleeve is held by the friction of the circuit contacts, until on lowering by the winch the boss, passing the two balls, bears on the guide sleeve, thus bringing the weight of the lamp into action to withdraw the contact pins from the bushes, when the sleeve falls down to its original position.

The strain release without arc lamp coupling is of practically the same construction as the above description, but the friction necessary to retain the ball sleeve in its top position is in this instance produced by two flat springs acting on the sleeve.

The main advantages of this new type of coupling and strain release are that all movements which are in any way controlled by the action of the winch are definitely limited by fixed stops, and also the use of locking balls whose movement is restricted to a definite path, but uncontrolled by any mechanical connections. The whole mechanism is without joints or pins, which might lead to stickiness and consequent failure. If at any time it is necessary to take it apart, only one screw has to be withdrawn to release every part of the mechanism. All parts carrying current are insulated throughout with mica and porcelain, and the whole coupling is enclosed in an enamelled sheet metal cover, rendering it perfectly rainproof, whilst the sleeve, fitting tight against the cover, prevents dust entering into the coupling.

A NEW METALLIC FILAMENT LAMP

A NEW incandescent lamp will shortly be placed on the market, by the Bryant Trading Syndicate, Ltd., of Highbury, which is not only of British manufacture, but also of British invention. The filament is an alloy of tungsten and some other metals, and burns at from 0·8 to 1·5 watts per candle, according to the life and candle-power of the lamp. Thus the 115-volt 20-c.p. lamp runs at 0·9 watt per (Hefner) candle, and

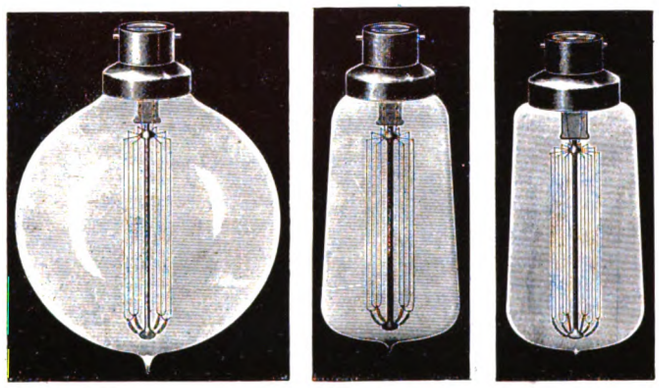

Fig. 1. Fig. 2. Fig. 3.

100 and 200-volt "Metalite" Lamps, showing Method of Supporting Filaments.

has a life of over a thousand hours. This same lamp, run on a 100-volt circuit, would, according to the pamphlet issued by the manufacturers, give 10 c.p. at an efficiency of 1·5 watts per candle. A 34-c.p. 200-volt lamp can also be obtained. This lamp is illustrated in Fig. 3. Fig. 2 shows the 17-c.p. 100-volt lamp, and Fig. 1 shows an alternative shape of the bulb. It will be seen from Fig. 3 that the 200-volt 34-c.p. lamp consists of six filaments arranged in series. An alternative design for this lamp has nine filaments, the length of each doubled filament being $2\frac{3}{8}$ in. The 100-volt lamp has four or five filaments

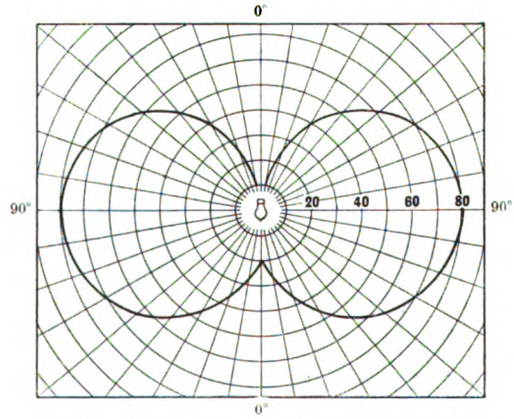

Fig. 4.—Polar Curve of "Metalite" Lamp.

in series. The filaments are cemented to the supporting wires at the top, and are also supported at the bottom by means of a zigzag spring. Where these springs come in contact with the filaments they are coated with a substance which prevents them from sticking to the filaments. The filament itself is particularly smooth, and has the appearance of a very fine steel wire. The finest filaments have a diameter of 0·0264 mm. It is claimed that the blackening of the globe is not so noticeable as with other lamps; and this, it is said, is due to the fact that no carbon-bearing paste is used in the process of making the filaments. Serious blackening does not take place unless the lamps are run at an efficiency of 0·5 or less watts per candle, when the temperature is so high that the filament commences to volatilise and the metal condenses on the surface of the glass. The lamps will burn at any angle, but it is not recommended to burn them otherwise than in a vertical hanging position. On account of the symmetrical arrangement of the filaments, the horizontal distribution of light is perfectly uniform. The distribution in a vertical plane is shown in Fig. 4, which is the polar curve for a lamp without any shade. With a suitable shade the illumination in a downward direction can, of course, be considerably increased. Fig. 5 gives the results of tests on a 90-c.p. lamp (presumably 120 volt). It will be seen that the c.p. rises to 95 and then falls to 90 again after a life of 1,000 hours. The current taken by the lamp falls steadily from 0·9 to 0·85 ampere, and the watts per candle fall to about 0·8 after about 60 hours, and rise again to slightly over one watt per candle after a life of 1,000 hours. Other tests have shown that the lamp will withstand overrunning to a considerable degree, as the resistance increases rapidly with increasing temperature. It is stated that

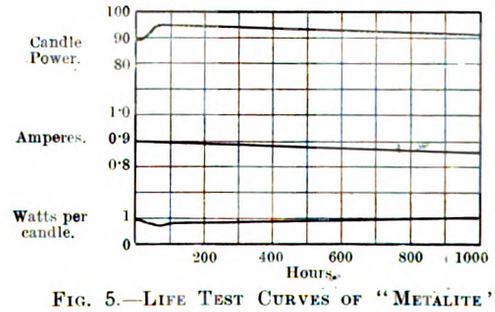

Fig. 5.—Life Test Curves of "Metalite" Lamp.

the lamps actually run better with alternating current than on direct current, and better with high than with low frequency. The lamps will be obtainable for all voltages from 1·2 volt to 250 volt, the lamps for 250 volt having candle-powers ranging from 42·5 to 188 c.p. The 10-c.p. lamp consumes 1·25 watts per candle, but the average consumption may be said to be one watt per candle. The process of manufacture is the invention of Mr. F. Harrison, who has also invented a wrapper for packing the lamps. This latter is simply a paper bag filled with wood-wool, but has proved itself so efficient that the manufacturers guarantee to replace any lamps whose filaments are broken in transit, so long as the broken lamps are returned within three days. The lamp has been named the "British Metalite."

Denmark Telegraph and Telephone Service.—Reporting upon the finances of Denmark for the year 1906-07, Mr. J. C. T. Vaughan, Secretary to His Majesty's Legation at Copenhagen, states that the telegraph service shows a slight increase over the previous years, and would not call for notice were it not that the State telephone service is included under this head. The revenue from the telegraphs was £79,375, from the telephone service £30,689, and from other sources £5,997. The total revenue was thus £116,061, and after deducting expenditure there was a surplus of £11,018, compared with £10,879 in the previous year. The individual figures for the year 1905-06 were: telegraphs, £76,963; telephone, £26,949; other revenue, £4,963. From the above it will be seen that the revenue from telephones is increasing rapidly. In Denmark, only the interprovincial, the inter-communal, and the international telephones are worked by the State, whilst the local telephones are worked by private limited companies, to which the State has granted concessions,

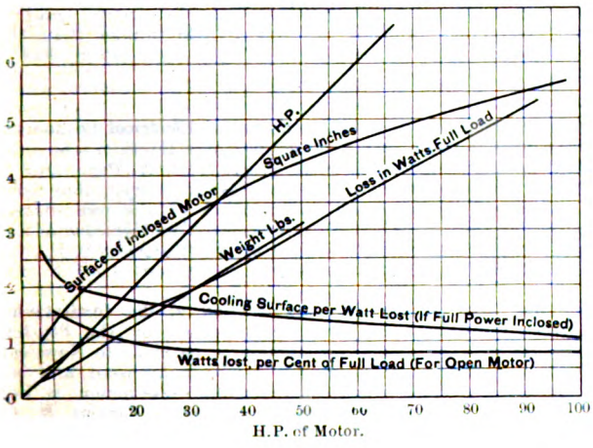
HEATING OF VENTILATED AND ENCLOSED MOTORS



MR. WILSON HARTNELL read a Paper on the above subject last Thursday before the Leeds Local Section of the Institution of Electrical Engineers. He remarked that the evolution of the continuous-current electric motor during the last fifteen years had resulted in a gradual decrease in size for any given output, but that the heat produced in the armature and shunt winding was no greater than of old. In modern machines, the heat produced by losses in the teeth and armature discs is serious, with a dense magnetic flux in the air-gap; and can only be kept within reasonable bounds by a moderate surface speed of armature, and the heat due to the carbon brushes is considerable with low voltages. With a surface speed of 1,500 ft. per minute the loss due to friction, and the drop in volts between the carbon and copper, may easily be equal to from $1\frac{1}{2}$ to $1\frac{3}{4}$ watts per ampere per brush.

The heat thus produced can only be dissipated by heating the motor itself, by radiation, or by conduction to a flow of cool air, that is by ventilation.

The relative change of the value of these effects, for a series of motors an assumed average weight, cooling surface and loss of watts, as the size of the motor increases, may be seen from Fig. 1.

Radiation.—It will be seen that the cooling surface per watt of motor under 5 h.p. is nearly double that of motors over 50 h.p. The difference in the effectiveness of the cooling surface is far greater. For the hotter air inside the larger enclosed motor is near the top, the bottom of the motor remaining markedly cooler, and therefore the radiating surface less active. Also the magnet case may be three or four times as thick in the larger motor, rendering the escape of heat of the metal proportionately less.

When an enclosed motor is required of more than, say, 3 h.p., the usual means of obtaining the requisite cooling surface is to take a motor of larger size and reduce the output, the armature current being reduced—and therefore the armature reaction—and also the flux density in the air space and ampere turns in

Fig. 1.—Averaged Particulars of a Set of Motors.

the poles. This reduces the heat due to losses in the copper, and still more the heat due to core losses. This, however, makes a costly motor for continuous working, even for moderate powers. A more economical arrangement for an enclosed motor is to place an open motor that may be fully loaded under a thin sheet-iron cover with ample inspection doors.

Ventilation.—The cubic feet of air required to keep the temperature rise below 72° is probably not less than the quantity tabulated, viz., about 9 cub. ft. per horse-power per minute for the smaller motors under 10 h.p., and about 5 cub. ft. per horse-power per minute for motors over 30 h.p. Experience shows that large open motors working to their full load can, by the aid of ventilation and radiation, be kept within the limits of 72°. But when wholly enclosed they can only be kept cool by forced draught. From rough estimation it seems that at least double the quantity of air per minute is then required.

Electric motors, viewed in regard to their means of cooling, may be divided into eight classes. (1) Entirely open, having their bearings usually on a bed plate which carries the magnets. Suitable for large motors, say, over 100 h.p. (2) Protected open, the bearings carried by open covers at each end of the magnet case. This is the ordinary modern motor, say, from 100 h.p. to 2 h.p. (3) Enclosed ventilated. The same as No. 2, but with the openings covered by wire net or perforated metal. These are used in factories where the open motor is assumed to be less safe. If the mesh be not less than 4 per inch the ventilation is not much interfered with, but if the mesh be

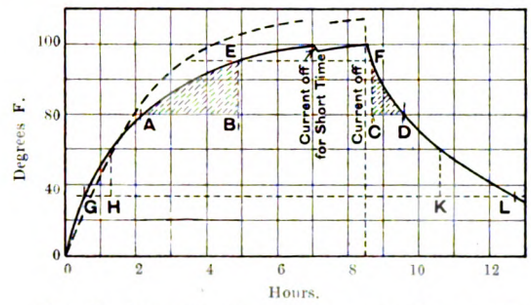

Fig. 2.—Heating and Cooling of a Magnet Coil.

much less not only is the ventilation much impeded, but the wire-work is apt to become choked with dust and fluff, and the safety of the motor endangered. (4) Same as No. 2 or No. 3, but with a forced ventilation by means of a fan on the armature and a diaphragm or its equivalent to divide the fan suction from the delivery. This is necessary in an exceptionally warm place. (5) Totally enclosed. These are required for special purposes, and usually necessitate a considerable reduction in the output. (6) Covered motors. The same as No. 2 fully loaded, but covered by a roomy thin sheet-iron case, practically dust-proof, with openings for oiling and inspecting the brushes, the pulley standing outside the case. (7) Open covered motors. The same as No. 6, but with a smaller cover made wholly or in parts of fine wire netting. The large area of wire-work prevents the tendency of any draught to cause the fine mesh to get clogged, and the motor fully loaded would be as cool as if unenclosed. This is specially adapted to textile mills where floating fluff is found. (8) Totally enclosed, but with forced ventilation like No. 4. This is necessary (*a*) when the motor is working in fumes very injurious to the motor, fresh air being sucked into the motor from a pure source through a pipe and discharged near the motor; (*b*) when the motor may be surrounded by inflammable gases, as sometimes in mines, the same air being circulated again and again through the motor and a cooling arrangement. Total enclosure with forced ventilation has been used to cool very large dynamos, cool air being drawn from outside the dynamo house and hot air discharged also outside.

From tests made to show the reduced power permissible, if a motor be totally enclosed and continuously loaded, it may be said that below 3 h.p. the loss of power may be inconsiderable; but a 20-h.p. open motor, when totally enclosed, is but little more than equal in power to a 10-h.p. open motor. A 50-h.p. open motor could only give 21 h.p. with a permissible temperature of commutator. To obtain the minimum temperature with the reduced output the winding had been specially arranged. In short, whilst the power of a modern open motor is chiefly a function of its magnetic flux, when totally enclosed the power becomes a function of the area of its casing, considerably influenced, however, by its environment, that is, by the exchange of radiated heat with its surroundings, or the motion of the surrounding air.

The author then proceeds to describe some experiments with a 60-h.p. motor running at 1,000 revs. The iron losses were measured by driving the armature by another motor, and noting the increase of power taken when the fields were excited. The tests were repeated with an unwound armature with similar results. The armature discs were then removed, bored, and fixed on a gun-metal bush—the end plates for supporting the end winding were turned thinner, and the cylindrical part for supporting ends of the windings were made shorter and thinner. The end plates were also separated from the stampings by paper discs. This made a slight improvement after two hours' run with air at 60° F., the rise of temperature in the slots was 54 and in the centre of the core 66. Finally the armature was rebuilt with Messrs. Sankey's Stalloy stampings

Digitized by Google

and tested unwound, but with the slots filled with wood and the magnets excited. The rise of temperature in two hours was 8° F. less than before, showing a slight advantage over ordinary stampings. The armature was wound and a fan fitted to the end of the armature to circulate the air inside. It was then tested as a totally enclosed motor, with a load of 58 h.p. for three hours, with the following results:—Rise of commutator, 111°; field coils, 88°. It was again tested totally enclosed for eight hours, but with a stop of eight to ten minutes every hour (after the first four hours) to take temperatures. Load, 59 h.p. The final temperature rises were (air at 70° F.): commutator 170, armature 149, field coils 125, air inside 105. There was not much increase of temperature after the first four hours, but the temperatures then were impracticable. The fan was then removed and the motor ran at 59 h.p. as an open motor for eight hours, with the ventilating slots on the periphery of the end covers also opened; the final temperature rise with the air at 62° to 69° was: commutator 58°, field coils, 48°, armature 68° F.

A 50-h.p. motor totally enclosed at about 450 revs. per minute keeps reasonably cool with 20·5 h.p. This power probably would be the working limit at standard speed. The cooling surface of the totally enclosed motor per watt lost should be, apparently, not less than 3½ to 4 sq. in.; but this depends on outside ventilation. On long tests the temperatures have often been known to go down after three or four hours, due apparently to draughts caused through opening doors.

The convex curve (Fig. 2) shows the gradual rise to a maximum temperature of an overloaded field coil of a dynamo (without an armature) and the concave curve the shorter interval of time to reduce the higher temperature after the current is cut off. Thus in this curve, if any line *ABCD* be drawn, *AB* represents the time required to rise to a particular temperature *BE* (measured outside the coil) and *CD* the time to cool. For the higher temperature which illustrates practical work *CD* is small compared with *AB*. The dotted line shows the average internal temperature calculated from the reduced current as the temperature rose. The coil was fully exposed to the air, and it was noticed that the temperature between the coil and the magnet ring was the same as outside the magnet ring near the pole. In enclosed motors the outside of the case may at times be 20° F. cooler than the magnet coils inside. This advantageous cooling with intermittent loads can only be obtained when there is a considerable difference of temperature between that of the air and the highest permissible of the motor. If the air be very warm, so that this difference is comparatively small, the motor gets hot in less time than it cools. It will be seen on Fig. 2 that *GH* is less than *KL*.

It may be noticed that there is no such thing as a gas-tight motor, even if the shaft worked through a stuffing box. The expulsion of, say, 15 per cent. of the enclosed atmosphere when it was heated, and the entry of the same amount of gaseous air from the outside on cooling, would cause the average condition of the atmosphere outside and inside soon to be similar. To enclose a motor tightly to keep out noxious gases is a delusion. In an explosive atmosphere they must be totally enclosed and strong enough to withstand an internal explosion.

Experience with open motors exposed to various noxious chemical fumes shows that although the motor's appearance may be spoiled and soldered joints affected, yet the motors last so long that it is better to let them wear out and buy new ones rather than put up with the troubles from enclosing them. In the author's opinion the reasons given for totally enclosing any but very small motors (Class 5) are usually mistakes. In the case of insurance risk they tend to defeat the object in view. In nearly every place where power is required for manufacturing, open motors may be used and easily protected against the real or supposed dangers of its particular environment. Enclosed motors with a current of air forced through them either by means of a fan or chimney may be considered as open motors so far as heating is concerned. The conclusion is that totally enclosed motors (Class 5) are under great disadvantages, and in general their use can be avoided.

DISCUSSION.

Mr. Harding Churton (Leeds), in opening the discussion, prefaced his remarks by saying he had not had an opportunity of carefully considering the Paper, and then proceeded to read some elaborated notes on experiments made by himself on alternating-current motors, which he contrasted with the results obtained by Mr. Hartnell on direct-current motors. He failed to arrive at an agreement, and asked for further information respecting the tables given in the Paper.

Mr. F. T. Chapman (Leeds), referring to the question of cooling totally enclosed motors in mines, said attempts had been made to get over the heating difficulty by enclosing the motor in a case of fine wire gauze on the principle of the Davy lamp. Experiments in the workshop have given satisfactory results.

Mr. W. B. Woodhouse (Yorkshire Electric Power Co.) was of the opinion that the conclusions arrived at in the Paper could have been predicted, as they were the same as occur with a transformer. The effect of windage in reducing the temperature does not take place in an enclosed motor. Machines of the open type which depend on natural ventilation of the armature can be correctly designed, but they would not be satisfactory as enclosed motors. Designs including a system of forced ventilation were the best for large enclosed machines. He referred to an installation in a spinning mill, where the motors were fixed over an air duct which was in direct communication with the outside. The air, after passing through the motors, was discharged into the room. This plan gave satisfactory results. Mr. Hartnell's system of using large sheet-iron covers, with ample inspection doors, for open type motors he considered a good plan. One of the advantages of using alternating-current motors in factories was that fire insurance offices only demanded a covering of wire netting, whereas direct-current machines had to be entirely enclosed.

Prof. G. D. Aspinall Parr (The University, Leeds) wished to know if the Stalloy stampings referred to were the same thickness as the stampings they replaced. He was under the impression that Stalloy was a great improvement on the ordinary metal used for armature discs, but the author's experiments did not appear to confirm this.

Mr. A. J. Cridge (Sheffield Corporation) considered the Paper an eminently practical one, and hoped it would be followed by another on the same lines, but dealing with alternating-current motors. Referring to protecting motors with a sheet-iron case, he said it was not applicable to alternating-current motors, owing to induction in the cover itself, which heated it up.

Mr. W. F. Mylan (Sheffield) agreed with the author that it was impossible to make gas-tight motors, and the proper course to adopt was to make them strong enough to withstand internal explosion. He also was of the opinion that as a general rule there was no necessity for totally enclosing motors, and that so far as insurance risks were concerned they defeated the object in view. A fruitful source of trouble was the lack of proper attention resulting from being covered up.

Mr. H. C. Jenkins (Sheffield), referring to the use of motors in mines, said the present tendency of users was to adopt open type machines wherever possible, and in gassy mines electromotors should not be used at all, the risks being too great.

Mr. Hartnell, in a somewhat discursive reply, said the Stalloy stampings referred to were a little thinner than those they replaced. In his experience forced ventilation was the best way of ventilating a motor.

Leeds Local Section of the Institution of Electrical Engineers.—At the general meeting last Thursday Mr. H. E. Yerbury was elected as chairman, in place of Prof. G. D. A. Parr, and Mr. Rogerson vice-chairman, in place of Mr. Yerbury. The following gentlemen were elected as members of the committee:—Messrs. W. Emmott, W. B. Woodhouse, J. W. Hame, and J. M. Smyth, in place of J. W. Beauchamp, W. Hartnell, S. D. Schofield, and H. H. Wright.

Summer Tour of the Students' Section of the Institution of Electrical Engineers.—It has been proposed by the Students' Committee that the annual visit this year be made to Newcastle-on-Tyne and district. The matter has been discussed, and some preliminary arrangements have been made. Permission is being asked to see the following works:—Messrs. Parsons & Co. Heaton; Messrs. Armstrong, Whitworth & Co., Ltd., Elswick; Messrs. J. & H. Holmes; the Newcastle Power Co.'s power station and system; the Castner-Kellner Alkali Co.; the Consett Iron Works; Messrs. Swan, Hunter & Wigham, Richardson (shipyard); Messrs. Hood Haggies, Wire Rope Works, Gateshead; Messrs. Clark Chapman, Ltd., Gateshead; and an electrically-operated coal mine. The visit will take place from July 6th to July 11th, and the party from London will travel by train on Monday, July 6th, breaking up on the following Saturday. Further particulars may be obtained from Mr. W. B. Thompson, Students' Hon. Secretary.

Rent of a Cable.—In the Chancery Division of the High Court on Thursday Mr. Justice Warrington tried an action brought by the South Eastern Railway Co. and Managing Committee of the South Eastern and Chatham and Dover Railway against the National Telephone Co., claiming a declaration that defendants were not at liberty to construct, use, or maintain a cable upon a bridge at Tonbridge Station except upon payment of an annual rental of £30, and with the consent of plaintiffs. The question was whether or not defendants were bound by a contract they entered into, by which they obtained a licence from the South Eastern Railway to place a cable with the roadway of the road passing over the bridge vested in the South Eastern Railway, or whether they were entitled to say now that the South Eastern Railway had no power to grant a licence. His lordship held that defendants were not authorised to construct the cable without the consent of the railway company, and the plaintiffs were entitled to a declaration, the defendants to pay the costs.

HIGH-SPEED ELECTRICAL MACHINERY

Newcastle Discussion

THE Paper by Mr. Gerald G. Stoney and Mr. A. H. Law, which was read on Thursday, April 2nd, at the London meeting of the Institution of Electrical Engineers, was further discussed by the Newcastle Local Section on April 6th. The Paper, which was given at considerable length in our last issue (page 543), together with a report of the discussion in London, contained an account of the development and present state of the designs of high-speed generators manufactured by Messrs. C. A. Parsons & Co. Particulars and drawings of machines for both continuous and alternating currents were given, including designs of historical interest as well as those illustrating the firm's latest practice The most notable features of the continuous-current machines are the retention of the bipolar form up to large sizes, the preference shown for smooth as against slotted cores, the avoidance of carbon brushes, and the employment of compensating windings without commutating poles. The alternators are more in accordance with prevailing practice elsewhere. The rotors are of the salient pole type, and a curious method of enclosing the field windings is adopted. The Paper concluded with a description of an ingenious arrangement for giving a compounding effect to alternators.

The Discussion was opened by Mr. J. Holmes, who considered that in the description of Mr. Parsons' 1884 patent hardly sufficient justice was done to that gentleman. There was really here the first indication of the barrel winding which in after years came into such prominent use. Referring to the 1885 experiment upon compensating winding, he would not altogether agree with the Paper's verdict that the fault was entirely due to insufficient ampere turns. He thought it might also be due to ineffective design for the purpose. In 1889 he was personally looking into this problem, and designed a form of compensating winding, which was applied to one of the machines sold by his firm, and gave perfectly satisfactory results. The arrangement is shown diagramatically in the figure in which the directions of current in the armature under the field, and direction of rotation was shown by Dr. Thompson's convention of "points and crosses." In order to neutralise the cross-exciting tendency of the vertical band of armature conductors he got the idea of placing a slot in the pole faces and filling it with ampere turns, giving an equal and opposite cross-flux. As it was mechanically difficult to make a single coil of this winding vertically, he placed coils on the side of the limbs, as shown, and found he had not only got a neutralising effect of cross turns, but could so shift the flux of lines through each pole-face that it was automatically

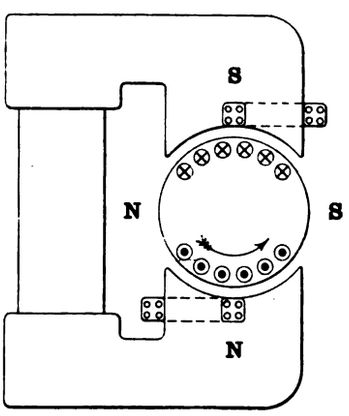

Diagram Illustrating Mr. J. Holmes' Remarks.

strengthened and weakened under the leading and lagging pole-tip in the precise way that was necessary to gain good sparkless commutation. If some such principle could have been applied instead of the arrangement shown in Fig. 1, perhaps the result would have been better. The design of armature in 1889, involving insulated discs at the end of the armature, reminded him of the Edison "Jumbo" dynamo, which had the same arrangement. The mention of the fact that in some of Messrs. Parsons' recent armatures of large size the conductors have been laid in slight grooves in the core reminded him that he himself had used a similar arrangement—having had, in fact, a patent for the same thing, which he had not upheld. The mention of brass-wire brushes was interesting, as lately carbon brushes, such as the Morganite brush, had been used, while the Westinghouse Co. had, he believed, in a recent machine used the radial surface of the commutator, placing the brushes sideways with the idea of avoiding jumping. The Morganite Co. had also introduced a special pneumatic-pressure brush-holder which, he had heard, was satisfactory on high speeds. The point mentioned as to the necessity of fixing the end windings of high-speed machines as firmly as possible was one of great importance. Even on slow-speed machines he had seen cases of violent distortion owing to insufficient security at these parts. The Paper mentioned the static balancing of armatures on knife edges. At one works which he saw recently the knife edge was superseded by a surface six inches wide, carefully planed up and kept level, the idea being that in a knife edge the surface of contact was so small tnat the weight of a heavy armature resting on it would cause the metal at that point to dent and sink in, prohibiting the armature from rolling well.

Mr. Turnbull, as an old Parsons man, referred rather humorously to some of the early difficulties. With reference to the compounding device mentioned near the end of the Paper, he believed that Messrs. Hookham many years ago used similar compensation windings on continuous-current apparatus. He would like to know the effect on the commutation of the exciter of the alternating fluxes superimposed on its ordinary flux. With reference to Morganite brushes, he had had some rather unsatisfactory experiences with some of an early pattern, but he believed that the Morganite Co. had since that time very greatly improved their brushes.

Mr. Davidson said that the compounding of the exciter mentioned in the Paper had been applied to about seven machines by Messrs. Parsons, ranging from 200 kw. to 750 kw., and no trouble had been experienced with the commutation. point concerning the working of these leakage paths was that the iron of the magnet must be saturated, and also the air-gap of the exciter is abnormally large. In ordinary machines it would be about $\frac{3}{8}$ in.; in this it was about $\frac{3}{4}$ in. Although the current in one phase may at an instant tend to assist the flux of the magnets through the bridge piece, the sum result of the superimposed alternating flux is to effect a gain of approximately half the leakage. In the first machine fitted this way the increase of exciter voltage when load came on the main machine was about 15 per cent. In a recent machine this rise could be brought up to 60 or 70 per cent. The practical effect is therefore that an alternator may have a very bad drop which can be compensated by increasing exciter voltage. To show how perfect the action was, one machine giving 500 kw. at 500 volts was connected up intermittently with a non-inductive resistance of full capacity, which was switched on and off. A glow lamp connected to the machine and placed in a dark room gave no perceptible flicker at these alterations of load.

Mr. Longman asked Mr. Stoney to give his impression of the performance of the Morganite brush with pneumatic brush gear, as the expense of heavy current brushes was heavy throughout a year. What result would the radial commutator have on life of brushes and commutator? Was there much sideplay in a turbine, and would this affect radial commutators at all? A displacement of 1/100 in. would effect sparking. With regard to the compensating device, would the fact that there was leakage round the top side of the exciter poles and not round the bottom affect the commutation? He had noticed, in some high-speed machines, that one bearing was always insulated, this being at one end of the shaft. There were several volts across that bearing and earth of alternating voltage. Was it of the same frequency as that of the machines, and to what action was it due?

Mr. R. H. Barbour wished to have one or two difficulties in the electrical and mechanical details of construction cleared up. He would like to know whether, for keeping the commutators quite true, the steel rings were found sufficient. In the use of carbon brushes the slightest irregularity—perhaps too small to be detected by a lead pencil—would set the brushes in disorder. It would be interesting to have details of the wear of brass brushes on copper commutators, as there might be some cutting. The Paper, in dealing with compensating windings, made no mention of placing separate poles between the ordinary poles and putting a winding on these. It mentions the method of varying effective resistance, but refers to the inductive effect on such an arrangement. It has, however, been found to answer properly if, instead of the usual non-inductive resistance being placed in shunt, the adjustment is made by means of a shunt having induction. He had noticed that the shaft shown in the latest machine illustrated was discontinuous. With the use of such shafts, was it not difficult to make the machine run true and balanced? The principle involved in the exciter, whose voltage is augmented by a flux due to alternating currents, is somewhat similar to the self-exciting alternator, where three-phase currents pass through a two-part commutator and are transformed to unidirectional currents for the field. The operation of this machine is satisfactory.

Mr. F. O. Hunt, in reference to the use of steel for binding

Digitized by Google

wire, asked if manganese steel had ever been tried. It had a negligible magnetic effect. Why should there be difficulty in running self-excited compensated dynamos in parallel? He was disappointed that the Paper had not dealt more fully with the question of flashing over. The question of balancing was interesting. He believed that in some American shops the knife edge test was not solely relied on, but an actual running balance was experimentally found.

Mr. LAW, in reply, mentioned that in the early days of experimental compensation windings on the lines shown by Fig. 1, Mr. Parsons had tried the effect of using not one hole only, but three, through the poles, in which to place his windings, thus foreshadowing still more closely modern practice. The carbon brush question was not mentioned in the Paper, as they were quite certain that it would crop up in the discussion, and they wanted to reserve to themselves the last word on the subject. This was that dynamos running at high speeds had given good results with carbon brushes. The high surface speed on the commutator was likely to lead to undue heating of the commutator. As time went on the surface would get rough, but this could be cured by a little polishing occasionally. Messrs. Parsons have now about half-a-dozen dynamos under construction with carbon brushes. At the same time they were not at present making carbon brushes their standard design. They preferred to make the commutators, even when fitted with metal brushes, of ample size to receive carbon brushes should at any time sufficiently good designs of brush and brush-holder appear on the market to warrant the change. Two of the oldest makers of high-speed electrical plant, Messrs. Brown Boveri and Messrs. Parsons, used metal brushes. Messrs. Brown Boveri have carbon brushes in front of the metal ones in order, as they expressly say, to lubricate the surface of the commutator. They had had no experience with the Westinghouse type of commutator. There would necessarily be a higher surface speed at the outside diameter. For a 300 to 500-kw. Parsons dynamo the surface speed of the commutator would be about 3,000 to 5,000 ft. per minute. With the Westinghouse type he imagined that the surface speed might go up to 11,000 ft. per minute, which would not be unsafe, but more difficult to deal with. The end play might also be a difficult matter to negotiate, as a flexible coupling limits end play to about 1/16 in. either way. So far as his knowledge of Morganite brushes went, they were ingenious and gave good results, but he failed to see why springs could not be equally well used. Mr. Holmes had referred to the importance of end connections, even on slow-speed machines. On high-speed machines, where the number of poles were few, the span of the end connections was correspondingly wide and trouble was more likely to ensue. The six-inch wide balancing surfaces had already been tried and found successful. They should, however, be hinged so that they may give a fair bearing on the shaft even when slight deflection occurs along the length of the shaft due to the weight of the armature. Mr. Turnbull referred rather humorously to the bursting of commutators. So far as he (Mr. Low) remembered, only one commutator had burst in the last eight years. With reference to the leakage-path device, it was at first thought necessary to distribute the flux equally at the top and bottom limbs, but a consideration of the old horse-shoe type of bipolar dynamo would show that distortion of the field in this way had very little effect on commutating properties. In answer to Mr. Chamen, he explained that a closed circuit for the alternating-current flux was better than an open one, though the latter could be used if the pole-faces were laminated. As Mr. Davidson pointed out, bad drops could be corrected by this device, though this could not be pushed too far on account of the possibility of the machine encountering heavy inductive loads. The leakage-path device had three paths, one in each phase, but it was possible to secure results with one phase leakage-path only, leaving the two other phases idle. Also it was possible to use a current transformer giving a single-phase current from three three-phase currents. With reference to the insulated end bearing, it was difficult to tell the frequency at present, though it was supposed to be that of the machines. Experiments would shortly be made with an oscillograph to test this. Its presence was due to the action of the dynamo as a unipolar machine as regards its stator, bedplate, bearings, shaft, and armature. A question had been asked as to the life of commutators of high-speed dynamos. An 1,800-kw. dynamo at Manchester had its commutator guaranteed for two years. As the result of gauging after considerable running, its probable life was determined at 10 to 12 years, before compensating winding was introduced. Now its probable life was much increased. Referring to the effect of interpoles, it was difficult to adjust the shunt inductive resistance for variations of voltage such as from 460 to 500 volts (lighting to traction voltage). Moreover, inductive shunts looked likely to be big and expensive. Discontinuous shafts were an interesting study. In large machines, such as those at Carville, the body of the shaft was made of high permeability steel of 30 tons tensile strength, while the ends had 40 tons tensile strength, but were of different physical properties. In reply to Mr. Hunt, manganese steel has the difficulty that it is so refractory as to be impossible to draw into wire. With regard to flashing over, he claimed that this evil was practically absent from two-pole dynamos. Regarding running balance, the revolving parts were at Messrs. Parsons run up much above speed in a sort of armour-plated house.

HAMMERSMITH-PUTNEY TRAMWAYS

THE Highways Committee of the London County Council has prepared a report with regard to the tramways from near Hammersmith Broadway, *via* Queen Street, Fulham Palace Road, High Street, Fulham, and across Putney Bridge to a point in Lower Richmond Road. The length of this route is about 2⅛ miles, and the Council's Act of 1902 prohibits the use of any system of overhead electric traction on the tramways. The extension of these lines from Hammersmith to Harlesden is being constructed on the overhead trolley system of electric traction, and, with a view to the construction in the near future of a through route from Putney to Harlesden on this system of traction, authority is being sought by the Council in the present session of Parliament for an amendment of the Act of 1902 so as to enable the overhead trolley system of electric traction to be used on the Hammersmith to Putney tramways. The greater portion of the route is situated in Fulham, and the Fulham Metropolitan Borough Council has agreed to the proposed adoption of the overhead trolley system.

The construction of the tramways in question is included in the programme of tramway works for 1908-9. The Highways Committee consider the construction of them to be a matter of considerable importance from the traffic point of view. The lines will join the Council's other lines, and will also be closely adjacent to those of the London United Tramways (1901), Ltd., at Hammersmith, and when the arrangements already approved by the Council for the widening of Hammersmith Broadway are carried out, it will be possible to run through services of cars from Putney to Harlesden. The Council has already approved estimates amounting in all to £20,320 in respect of preliminary works in connection with the construction of these tramways. These preliminary works have been put in hand, and include the diversion of gas and water mains along the route, and alterations of the south-western approach to Putney Bridge in order to provide improved terminal facilities for the tramways. Various street widenings along the route were authorised by the London County Council (Tramways and Improvements) Act, 1902. The execution of these widenings are now practically completed. It is necessary, however, in order to complete the purchase of certain property of the Ecclesiastical Commissioners for the street widenings, that the Council should pass a definite resolution to proceed with the construction of the tramways.

The electric power for working the tramways will be obtained from the Greenwich generating-station. No further buildings will be required, as arrangements have been made in connection with the Hammersmith to Harlesden tramways for the erection at Hammersmith of a portion of the car-shed which is to be established there, and also of a temporary sub-station, and these buildings will serve the Hammersmith to Putney tramways. The length of the tramways will be equivalent to about 4¼ miles of single track, and the total estimated cost of the construction and equipment of the lines on the overhead trolley system of electric traction, exclusive of buildings, and of the preliminary works mentioned above, is as follows:—Trackwork, &c., including special work, and £7,800 for rails, £34,100: overhead equipment, £5,650; cable-ducts, &c., £3,500; cables and feeder pillars, £3,000; rolling-stock, £5,700; sub-station plant and equipment, £2,500; total, £54,450. In view of the urgency of the matter the Committee suggest that the operation of the standing order which relates to proposals involving capital expenditure exceeding £5,000, should be suspended so as to enable this recommendation to be dealt with by the Council before the Easter recess.

The Committee therefore recommend that, subject to Parliamentary authority being obtained by the Council in the session of 1908 for the use of the overhead trolley system of electric traction on the tramways in question, the estimate of expenditure on capital account of £34,700, submitted by the Finance Committee, be approved in respect of the construction and equipment of the tramways on that system, namely, trackwork, &c., excluding rails, £26,300; overhead equipment, £5,650; feeder pillars, £250; sub-station plant and equipment, £2,500; total, £34,700.

The Finance Committee, having considered in its financial bearings the above estimate, submit the same as chargeable to capital (short period) account. When the question of the construction of this line was last before the Finance Committee, in December, 1906, it was estimated that the working would result in an adverse balance in the first year of £3,005 on the basis of a 4-minute service, or £995 on the basis of a 3-minute service, before providing for renewals. If 1d. per car mile be accepted as the standard for renewals, provision on this basis would increase these adverse balances to £4,221 and £2,668 respectively. These estimates were based on the assumption that the line would be reconstructed on the conduit system, and the substitution of the overhead trolley system, as is now proposed, would reduce the estimated adverse balances to £2,761 and £1,118 respectively for the first year, which would decrease by about £127 and £132 a year as the debt is paid off. It must be borne in mind, however, that the tramways account is at present bearing debt charges to the extent of over £2,000 a year in respect of street widenings and other works already carried out on this route.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

THE *Revue d'Électrochimie et d'Électrometallurgie* of March has an article upon the fusion and production of glass in the electric furnace. The article, which deals with the subject from the first experiments by Reich in 1881, is practically an historical survey of the various methods which have been tried. There are a good many difficulties in the employment of electrical energy for the fusion or making of glass. One difficulty is the very local heating which is apt to be produced by the electric arc. In most of the furnaces described, the mixture of sand, lime, soda, &c. which is employed for the manufacture of glass is caused to pass from a distributor through a series of arcs into a crucible placed below, the arcs being so arranged that after passing the last one the product is completely fused. Or it is caused to pass cascade-wise down a series of steps, and as it passes each step it is radiantly or directly heated by an arc. As a rule, after reaching the crucible it is kept in the molten condition by means of gas or other firing. One of the most interesting furnaces described is that of Brown, where the crucible is embedded in broken carbon, on each side of which electrodes are placed. When the current is passed, we thus have a resistance furnace produced, and the crucible is in the midst of the furnace. The article is to be continued.

In the same number, *loc. cit.*, there is also an article by Minet upon a new electric arc furnace. He thinks it necessary to give first of all a long description of various furnaces from that of Siemens, 1878, and then various forms of furnace experimented with by himself and others, perhaps in the next number—the article is to be continued—we shall arrive at the new furnace.

There is also an interesting article upon the preparation of aluminium carbide by C. Matignon. Moissan first obtained this substance by heating a mixture of aluminium and carbon in a carbon crucible by means of an electric furnace. Mallet heated aluminium and carbon to a temperature of 1,700°, but apparently was not able to convert it into the carbide. On the other hand, Frank repeated this work and obtained a carbide which on being added to water gave off a mixture of acetylene and hydrogen; it was probable, therefore, that the presence of impurities had led to the formation of calcium carbide. The carbide obtained by Moissan gave, when treated with water, methane

$$Al_4C_3+6H_2O=2Al_2O_3+3CH_4.$$

In 1901 Berthelot determined the heat of formation at 244·8 calories. From this high heat of formation he believed it should be possible to produce the carbide without it being necessary to employ the great heat of the electric furnace. By mixing 70 or 140 parts of aluminium with 24 parts of sugar carbon and oil of terebene, and heating the mixture in a Perrot furnace for 20 minutes, the carbide of aluminium was obtained, which, upon the addition of water, gave off 95 to 96 per cent. of methane.

The reaction can also be caused to take place by Goldschmid's method—that is, by mixing carbon and aluminium together and starting the reaction by means of a fuse Reaction between aluminium and benzene hexachloride can also be caused to take place by heating to 225°; the reaction is very vigorous, and takes place as follows:—

$$10Al+C_6Cl_6=2AlCl_3+2Al_4C_3.$$

"The Deposition of Zinc for Protecting Iron and Steel Surfaces," by S. Cowper Coles, is the title of a reprint from the *Transactions* of the Glasgow Technical College Scientific Society. In it the various processes of galvanising are described, beginning with that of dipping the articles into molten zinc. The author then describes the process of cold or electrolytic galvanising, and gives figures which go to show that this process is much more economical than the hot dipping process. By the old process the cost is given as 0·5688d., and with soluble zinc anodes as 0·3658d. per square foot. Of course, there are advantages and disadvantages in both methods. If the article is to be electrolytically galvanised, it requires a much more thorough and careful preparation than if it is to be galvanised by the molten process. Furthermore, in the galvanising of tanks, &c., any slight leaks which may be left by faulty joins are filled in by the hot process, but not by the cold process. On the other hand, articles plated by the cold, wet process will take on a very fine polish, and the coating is very even. The sheradising process is then described. In this process it will be remembered that metals can be galvanised by placing them in a box, covering them with zinc dust, and heating to a temperature of 330 to 400° C.; this is about 100° below the melting-point of zinc. After taking out the metal, it is found to be evenly covered with zinc. If the metal is cut it is noticed that the zinc has alloyed with the object to quite a considerable depth. Articles so treated will also take on a very fine polish. Another very interesting result which can be obtained is galvanising in relief. If the parts which it is desired should not be galvanised are coated with a stopping off composition, and then placed in contact with the heated zinc dust, the zinc is only deposited upon the parts which have been left exposed, so that by this means any desired form of pattern can be galvanised upon a metal. Finally, the Cowperising process was mentioned. In this the article to be galvanised is placed in a chamber into which a mixture of zinc vapour and hydrogen gas is led; by this means very brilliant effects can be obtained.

ELECTRICAL SCIENCE

British and American

The Chancellorship of Cambridge University.—Lord Rayleigh has been elected as the new Chancellor of Cambridge University in succession to the late Duke of Devonshire. Lord Rayleigh's Cambridge career commenced at Trinity College in 1861, and he became Senior Wrangler of 1865 and first Smith's prizeman. In 1879, when, on account of his well-known work in Physical Science, he had already been a Fellow of the Royal Society for six years, he succeeded the great Clerk Maxwell at the Cavendish Laboratory, Cambridge, as Professor of Experimental Physics, and during his five years' tenure of this position, he conducted classical experiments on the evaluation of the fundamental electrical units. He was for some years Secretary of the Royal Society and Professor of Natural Philosophy at the Royal Institution. His later scientific work, including his connection with Sir William Ramsay in the discovery of argon, is too well known to need recapitulation.

Short Spark Phenomena.—At last Friday's meeting of the Physical Society, W. Duddell exhibited an interesting experiment on the secondary current of induction coils. The induction coil was one of about six-inch spark length, and its primary current was taken from 100-volt mains through a resistance of about 30 ohms, and through a mercury break. In the secondary circuit were an adjustable spark gap and a thermal ammeter in series. The thermal ammeter read, of course, the root mean square of the current through it. Now the author showed that if the adjustable spark gap had its poles screwed up into metallic contact, the current through the thermal ammeter was a certain small figure; but if the gap was opened slightly, say to one-tenth of a millimetre, then a mean square current of many times the original value was registered. If the gap length was gradually increased, the reading increased till at a spark length of about one millimetre it was a maximum. As the spark length was further increased the reading diminished till at a spark length of five millimetres the mean square current became of the same order as it was when the spark length was zero. With further increase of spark length the thermal ammeter reading increased. The author showed also that rather unexpected phenomena occur when a galvanometer is used in place of the thermal ammeter. A galvanometer measures, of course, the mean current. When the spark terminals are in contact the deflection is zero. When the gap is a very small one the galvanometer deflection is considerable, and is in the same direction as that given by a single *make* of the primary current. As the length of the spark gap is increased the deflection grows to a maximum and then diminishes to zero. Further increase of the spark length causes the deflection to take place in the direction of the deflection given by a single *break* in the primary current. Of all these phenomena the author gave very slight explanation. The facts unfolded are nevertheless of interest, not only because they are somewhat paradoxical, but also because they may conceivably be of service in the testing of the secondary winding of an induction coil. In the discussion, A. Russell suggested that the explanation of the thermal ammeter experiments might lie in the well-known fact that in a circuit traversed by electrical oscillations, the impedance, and therefore the current, is a function of the inductance, the capacity, and the frequency, such that if the capacity and the frequency vary in opposite ways the function has a maximum and a minimum. In the case of the experiment just shown, the spark gap is, in effect, a condenser of small capacity and the circuit containing the gap has a determinate frequency. If the gap is lengthened the capacity is diminished, and the frequency increased, and thus the maximum and minimum of the experiment can be accounted for. S. Skinner called attention to some old experiments of J. J. Thomson on the electrolysis of steam, which seemed to have some bearing on the matter. The steam was electrolysed by the current from an induction coil, which, usually, as is well known, gives a unidirectional discharge; but in these experiments cited the electrolysis varied greatly with the length of the spark gap. With short sparks the hydrogen appeared at the negative ter-

Digitized by Google

minal, with sparks of medium length the hydrogen appeared at the positive electrode, and with long sparks the hydrogen appeared at the negative electrode.

The Carriers of Positive Electricity.—At the Royal Institution, last Friday evening's discourse was delivered by Prof. J. J. Thomson. The lecturer dealt principally with the problem of the nature of positive electricity. Though the disembodied negative unit of electricity is familiar enough to physicists, the ultimate particle of positive electricity has never been separated from masses of the size of the atoms or molecules of ordinary matter. Thus the particle of positive electricity has always been weighed associated with matter, the hermit has never been got out of his cell, though both persuasion and provocation have been applied in various ways. The lecturer summarised some of the main properties of positive rays, and then proceeded to show that in vacuum tubes the positive rays seem often to be issuing from regions they ought never to have appeared in. This was shown very emphatically by a helium tube containing a cathode made of two parallel triangular plates fixed close together. From such a cathode both negative rays (cathode rays) and positive rays (canal rays) can be seen simultaneously proceeding, for they are easily distinguishable in helium. Since the motion the rays possess is due solely to the action of the electric field in the tube on the carried charges, this experiment would seem to show that the "positive" carriers may sometimes be laden with negative charges. Here the lecturer stated his view that uncharged "positive" carriers may often be found in a vacuum tube; they may, because uncharged, reach the cathode in their wanderings, and these, becoming negatively charged, be repelled away from the cathode as so-called positive rays. The one characteristic of the positive carriers which is their real distinction is their large mass. By passing ionised gases between two very close parallel gauze strips kept at constant potential difference, the lecturer has succeeded in projecting the heavy particles in the gas with definite momenta along a tube and across a magnetic field. The field deflects the particles more or less according as their mass is smaller or greater. In this way using magnetic fields rising to 6,000 lines per square centimetre, he has succeeded in measuring the mass, and the relative number, of the positive carriers in air and in hydrogen. The conclusion he has reached is that about the same number of carriers in each gas have the mass of the hydrogen atom, another batch of carriers, also equal in the two gases, have the mass of the hydrogen molecule, while there are also batches of heavier objects not yet fully investigated.

Sir William Ramsay's Lecture in Vienna.—A lecture on radioactive gases was given last Saturday evening by Sir William Ramsay before the Electrotechnical Institute of Vienna. According to the *Daily Telegraph's* correspondent, almost all the Ministers, the entire staff of the British Embassy, and everyone enjoying a reputation in scientific circles in Vienna, were present.

Electric Discharges through Gases.—At the Royal Institution on Saturday last Prof. J. J. Thomson delivered the sixth and last lecture of the course on this subject. Most of the time was devoted to an explanation of the phenomena observed in an ordinary vacuum tube. If a section across the path of the discharge is considered, the current passing through that section is the same wherever the section is taken. Any variation in the number of carriers or particles must therefore be accompanied by a corresponding increase in the velocity and the electric force. The negative particles produced at the cathode by the impact of the positive particles got fewer in number as they proceeded along the tube, as they were driven to the walls of the tube. The velocity must therefore increase, and in the region of the negative glow the velocity was so great that fresh negative ions were produced by collision with the molecules, and the number of particles being increased, the velocity decreased. Where the electric force and the velocity were high, luminosity was produced. The number of particles would soon decrease, and the velocity would increase. Another luminous (high velocity) region would be produced, and again after the collisions a (low velocity) dark region. This was repeated along the tube, and produced the so-called striae. The narrower the tube, the more rapid the diffusion of particles, and the nearer the striae. A magnetic field also increased the loss of particles by driving them to the walls, and the striae were drawn nearer together. The total negative charge due to these negative particles was, the lecturer said, neutralised by an almost equal positive charge on the positive particles. At the surface of the anode, where the positive particles came from, there was a sudden drop of about 20 volts. Prof. Thomson then explained how it was that the luminous discharge ceased suddenly on a slight increase of the resistance in the circuit, and did not gradually die out. The curve expressing the relation between the current and P.D. for an exhausted tube was complex; that portion of it corresponding to the luminous discharge was convex to the (current) abscissa. A diminution in current then meant an increased P.D. Thus, if at the critical point the resistance in series with the tube were slightly increased, the necessary P.D., owing to the decreased current, would be larger than that available at the terminals of the tube, and the discharge would suddenly cease. Prof. Thomson then concluded the lecture with a few remarks on the electric arc. This, he said, was hardly a case of discharge through gases, but was a case of the discharge from incandescent solids. If a negative electrode were made red rot, it gave off a stream of negative particles whether it were surrounded with gas or not. The cathode of the ordinary arc was kept hot by the bombardment of positive particles from the anode. The cathode must be kept at a very high temperature, and so the cathode must be made of a substance which is a bad conductor of heat. The burning of the carbon cathode increased the temperature, and if this was hindered, as, for example, in the enclosed arc, the arc was more difficult to form owing to the decrease in the number of negative particles thrown off by the cathode. The lecturer then summed up the subject by saying that the two fundamental principles were (1) the motion of the charged particles, and (2) the production of fresh particles by collision. By applying these principles all the phenomena of electric discharges could be explained.

The Indian Institute of Science.—It is announced in *The Times* that the scheme for an Indian Institute of Science, which it is proposed to found by the munificence of the late Mr. Jamsetji Nasserwanj Tata, a prominent merchant and millowner of Bombay, is rapidly taking shape. A provisional committee has been appointed by Lord Minto, and building operations are to commence at once at the site which was given by Mr. Tata at Bangalore. The Government and the Maharajah of Mysore have contributed largely towards the cost. The chief work of the institute will be the establishment of departments of pure and applied science, and students who have passed through the Indian Universities will be trained so that they may apply science to the Indian arts and industries. The nearness of the great Cauvery power works, from which a supply of electricity at high tension will be obtained, has led to the decision to open a Department of Electrical Technology, and it is possible that a department of electro-metallurgy may also be established.

Continental

Longitude by Wireless Telegraphy.—In the *Comptes Rendus* of March 30th we find details of Bouquet de la Grye's proposals for an international hour signal by wireless. Chronometers and occultations are to be supplemented by a daily hour marked by a wireless wave capable of being received all round the world. The Eiffel Tower station has a range of 1,300 miles, and would cover the busiest portions of the Atlantic. For a world-wave, something bigger would be necessary. The Peak of Teneriffe has been proposed. It is 3,710 m. high, with an average gradient of $13\frac{1}{2}°$. The possibility of such a service has been acknowledged by Becquerel, Chairman of the Wireless Commission instituted by the French Government, and by Admiral Gaschard, who is in charge of the wireless service to Morocco. The latter does not, however, think that Teneriffe is necessary. A sea strand 6 km. long, such as is available at Guetn'dar, Senegambia, in the region of the trade winds, would be more convenient and quite effective. A beginning might be made with a service from the Eiffel Tower. The world-signal would have to be despatched at midnight, in order to get the maximum range of transmission along the dark half of the globe. The proposals have been referred to the Astronomical, Geographical, and Physical sections of the Academy, together with MM. Darboux, Poincaré, and Cailletet.

Number of Electrons in an Atom.—An interesting attempt to estimate the number of electrons contained in an atom is made by J. Bosler in the *Comptes Rendus* for March 30th. His result, derived from considerations of the energy displayed in radioactivity, goes to confirm Thomson's result that the number is of the order of the number expressing the atomic weight. According to Curie, a gramme of radium gives out 100 calories per hour. Rutherford estimates the mean life of radium at 1,300 years. This gives us an idea of the total energy available for dissipation, and due to the potential energy of the electrons and the positive elements (probably helium atoms) contained within the radium atom. The potential energy contained in a gramme of any substance may be put down as proportional to $N(ne)^2/a$, where e is the charge of an electron, N the number of atoms in the gramme, n the number of electrons in the atom, and a the radius of the atom. The latter probably varies with the atomic weight, and may be three times as great in radium as in hydrogen. Thus we get another estimate of the electrical energy in a gramme of radium. It is $2\frac{2}{3} \times n^2 \times 10^{13}$. The figure derived from the observed radioactivity and life period is 3×10^{16} ergs. Equating the two values, we find that n must lie somewhere below 10. The determination is, of course, very rough, but it should render a number of 1,700 electrons in the hydrogen atom very doubtful.

The British Association.—An advance programme of some of the arrangements for the forthcoming meeting of the British Association in Dublin has been issued. The meeting will commence on September 2nd with the Presidential address of Prof. F. Darwin, F.R.S., and the reception-room, which will be at Trinity College, Dublin, will be open the day before. The concluding meeting is fixed for September 9th. As already announced in Electrical Engineering, Mr. Dugald Clerk, F.R.S., will be president of the Engineering Section.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published April 9th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.
Names in brackets indicate communicators of inventions from abroad.

1907 Patents

1,373, C. A. Park and C. L. Mason. A device for use with the "Stone" system of train lighting, in which the dynamo is driven by a belt which slips if the speed is excessive. If the belt does not slip, the current may become excessive. The present device consists of a series solenoid operated switch which, if the current exceeds a certain predetermined amount, inserts a resistance in the main armature circuit. The resistance is again short-circuited on the current being reduced in value. Two claims, four figures.

6,649, British Thomson-Houston Co. (*General Electric Co.*). A method of providing machines of the compensated commutator type with a commutating field, without the use of interpoles, and particularly suitable for alternating-current compensated series motors in which there is not room for interpoles. The armature of the machine is wound with a fractional pitch approximately equal to or a little less than the width of the pole-face. The current in the coils of the slots opposite the interpolar space then neutralise each other, and it is only necessary to compensate along the pole-face, for which purpose a compensating winding is distributed along the pole-face. Furthermore, the short-circuited coils are just approaching or leaving the pole-tips, and so a commutating field of proper amount and phase can be produced at the pole-tips. A special shunt winding at the pole-tips can be provided, or that portion of the compensating winding situated at the pole-tips can be shunted with a non-inductive resistance, this causing the field at the pole-tip to have the necessary lag behind the main compensating field. Four claims, six figures.

7,181, British Thomson-Houston Co. (*General Electric Co.*). A system of control for electric winches for towing barges and other purposes. The winch, which is situated on the tug, is controlled by an electric motor, the motor being supplied with current from a generator, also on the tug. A device, consisting of two solenoids, one controlled by the current through the motor, and the other controlled by the variation in the effective length of the hawser acting on a screw and nut variable resistance switch, so controls the torque of the motor that the pull is increased when the distance between the ships increases and is decreased as the distance between the ships decreases. Thus, if the tug slows down, the hawser is reeled in to take up the slack, and if the tug suddenly increases in speed, the hawser is automatically lengthened to avoid shock, and then gradually wound in. Six claims, two figures.

11,166, J. S. Highfield. In high-tension direct-current systems it has been the usual practice to use a number of direct-current generators (each coupled to its prime-mover) in series. It is necessary to insulate each generator from earth, and consequently the generators have been supported on insulating bases, and coupled by means of insulating couplings to their respective prime-movers. To avoid the use of these insulating couplings, the prime-mover, which, according to this invention, may be a large unit, is coupled to an alternator. The alternator supplies current to a constant current transformer, the secondary of which is divided up into a number of equal sections. Each of these sections supplies current to a rotary converter and the direct-current sides of the rotary converters are connected in series. The rotary converters only need be insulated from earth, and no insulating couplings are required. When the demand on the station is small, one or more of the converters can be short-circuited, and this will not affect the current, as the transformer is designed for constant current. Instead of a single transformer, several in parallel can be used. Two claims, one figure.

11,523, W. Kneen and H. C. King. This specification relates to the points used in the conduit system for tramways, particularly where facing points are employed, and describes a mechanism for setting the slot points simultaneously with the operation of the rail points. This consists of push-rods, each of which is adapted to be maintained in operative engagement during the forward or setting stroke until it is moved sufficiently to set the point, when it is disengaged by a cam, so that its further motion is lost. Each rod on its rearward stroke resets itself ready for the next forward stroke, and moves back sufficiently to allow the plough to complete the movement of the tongue. Four claims, six figures.

16,710, Bruce, Peebles & Co. and La Cour. In machines the pole-shoes of which are fitted with amortisseurs of the usual type (*i.e.*, copper rods through the pole-shoes, the rods being parallel to the axis of the machine and being short-circuited by heavy end connections), the shoes may become unduly heated owing to currents generated in the amortisseurs by the local fluctuations of the magnetic flux in the pole-shoes, these fluctuations being caused by the irregularity of the slotted armature surface. If the copper rods are put in the shoes at an angle to the axis of the machine, these fluctuations do not induce current in the bars. The action of the amortisseurs in damping variations in the magnitude of the total flux is not impaired by this arrangement. Two claims, three figures.

20,372, V. Scholz. In the process of manufacturing metal filaments for incandescent lamps, from colloidal metals (see B.P. No. 28,154, of 1904, granted to Dr. H. Kuzel), the plastic threads are reconverted into a crystalline state by heating them to a white heat in a neutral or reducing gas. To prevent the filaments from becoming distorted while undergoing this treatment, they can be put under strain by hanging a small weight from the filament, or by causing a reaction between the current in the filament and a suitably placed magnetic field, or the above-mentioned weight can be acted upon magnetically. One claim, no figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.
Summaries of the more important of these patents will appear in our next issue.

1906 Patents

29,086, Lodge. Exciting Ruhmkorff coils.
29,398, Hewitt Apparatus for recording the time of signals on railways.

1907 Patents

1,596, Park & Mason. Electrically-operated switches.
6,932, Foster & Spoor. Electric igniting apparatus.
7,555, Handcock, Dykes & Smith. Electrical wiring.
7,556, Handcock, Dykes, & Smith. Boxes for electrical wiring.
7,557, Handcock, Dykes, & Smith. Boxes for electric wiring.
7,563, Friedheim. Electro-deposition of metal on hollow articles.
7,926, Hatfield & Lewis. Electric arc lamps.
8,020, British Thomson-Houston Co. (*General Electric Co.*). Systems of motor control.
8,388, British Thomson-Houston Co. (*General Electric Co.*). Systems of lighting by arc lamps.
8,629, Human. Utilisation of electrical energy in the case of intermittent loads.
8,860, Balachowsky & Caire. Driving wheels for electrically-propelled vehicles.
9,270, Cummins. Automatic electro-magnetic sanding gear.
10,931, Campbell. Electric incandescent lamp bulbs.
10,972, Porzellanfabrik Kahla, Filiale Hermsdorf Klosterlausnitz. Insulators.
12,913, Irving. Reciprocating electric motors.
13,342, Richardson & Vaughan. Electrical production of ozone.
13,403, Boult (*Soc. Anonima di Construzioni Meccaniche, Freni a Ricupero Cantino F. A. R.*). Starting devices for motors.
16,865, Brookes (*Asbestos Wood Co.*). Insulating materials.
16,968, Martin. Electrical resistance.
17,304, Summerscales & Pearson. Automatic switch point for overhead conveyors.
17,548, Milton. Inductor generators for ignition.
17,704, Marzi. Loud speaking telephone apparatus.
18,480, Schmidt. Electroplating metals.
19,101, Rawson & Sager. Electrical water-heater.
21,104, Fletcher. Magazine fuses for electric circuits.
24,983, Fidelmann. Pocket lighting appliances.
25,126, Cowper-Coles. Electro-deposition of metals.

1908 Patents

468, Siemens Bros. Dynamo Works (*Siemens Schuckertwerke Ges.*). Maximum demand meters.

Complete Specifications open to Public Inspection before Acceptance.

1907 Patent

24,802, Timar & Von Dreger. Apparatus for transforming electric currents.

1908 Patents

6,228, Grob. Method of producing a constant booster voltage with variable speed.
6,323, Steinert & Stein. Electro-magnetic treatment.
6,432, Kinsella & Hodgetts. Electrical alarms for tramcars.
6,453, Jirotka. Production of ozone.

Expiring Patents

No patents of electrical interest expire during the current week.

CATALOGUES AND PAMPHLETS RECEIVED

CURRENT TRANSFORMERS.—Two new price sheets, which form additions to Messrs. Ferranti's complete catalogue, have been issued dealing with current transformers for use with measuring instrument, and for operating relays, &c. One of these is the H open type for switchboard purpose. The cores are made up of best quality transformer-iron stampings, and the windings are insulated with mica and impregnated linen cloth or porcelain. With wound primaries, *i.e.*, sizes below 200 amperes, the primary winding is insulated and the core and secondary can be earthed. When the primary consists of a straight bar through the core—200 amps. to 500 amps.—then the secondary is the insulated winding and the core must be insulated from earth. The other leaflet gives particulars of a portable current transformer contained in a neat stained hard-wood box, provided with strong carrying strap and rubber buffer feet. Bolts are provided to enable the conductor to be bolted to the primary. These transformers have 800 ampere turns at full load, and are wound with especial care to avoid magnetic leakage. Their ratio is unaffected within wide limits of resistance in the secondary circuit. They are specially recommended for all indicating instruments, and will work several instruments in series, such as, for example, a wattmeter and an ammeter.

DIE FINISHED CASTINGS.—A leaflet from the Gratze Patents & Engineering Syndicate, Ltd. describes special castings of high finish which this firm manufacture. These castings are made in steel moulds under hydraulic pressure and in various alloys, which can be made to stand up to 14 to 16 tons tensile strain per square inch. The finish is excellent, so much so that screw threads can be easily moulded thereon and holes cast in the pieces so that practically no machining is required.

SIMPLEX CONDUITS.—A leaflet has been issued by Simplex Conduits, Ltd., containing translations into French, German, and Russian of a speech made by Mr. A. Lester Taylor, Chief Electrical Engineer to the Liverpool, London & Globe and the Royal Insurance Offices, at the opening of the new premises of Simplex Conduits, Ltd., in which he is reported to have said that conduit wiring with suitable accessories was the best and safest system it was practicable to adopt.

Kent Collieries Electrical Plant.—In the Official Referee's Court on Friday, Messrs. Ernest Scott & Mountain, Ltd., sued the Kent Collieries, Ltd., for £3,249, the balance of £5,780, cost of machinery and plant supplied, besides money paid by the plaintiffs by way of wages to men lent to the defendant company. The defendants denied liability, pleaded that the plant supplied was not in accordance with the contract, and on that ground they counterclaimed. Mr. C. A. Russell, K.C., appeared for the plaintiffs, and Mr. Bousfield, K.C., for the defendants. The plaintiffs contracted with the defendants for the supply of an electrical plant and driving engine at a cost of £5,780, and in addition £550 balance of the cost of a vertical spindle pump. There was another claim for £847, wages of men lent to the defendants. Other claims were for £105 for goods supplied, and £46 16s. 10d. for stripping and cleaning one of the pumps. The specification to which the plant had to work was to raise 1,000 gallons of water per minute against a head of 640 feet of water at 1,440 revolutions. All the allegations that the plant did not come up to specification the plaintiffs denied. The plaintiffs further said that it was contemplated that they were supplying engines and motors which would be worked continually or for an unlimited period, and that if the generators got overheated and broke down they did so because they were not used fairly or reasonably. The defendants, they said, absolutely worked one of the pumps to death, and it was now in a ruined condition. They further contended that the contract provided for the payment of the whole amount, irrespective of whether the machinery was tested or not.

Mr. Hodgkin, the Assistant Managing Director of the plaintiffs' company, said that he had advised the erection of duplicate plant in the first place, as the one set could not do the work continuously; or, failing the two sets, a stock of spare parts was of the utmost importance. The pumps were worked for a week or ten days down in the shaft, but were left all night without current passing through the motor windings. While cooling, moist air was drawn into the windings, and this had caused the trouble. The fusing of the coils, due to this, was, however, no indication that the motors were not according to the contract. Later, another pump was supplied to the defendants on loan. The first and second instalments of the account were paid, but defendants said that the third instalment was not due until their electrical expert had given his certificate. With regard to the temperature rise of the motors, one test showed that when the machinery was working 15 h.p. below the full load of 100 h.p. the temperature rose to 75° C. in one hour and to 101° C. after five hours, whereas the contract stipulated a maximum rise of 70° C. After another five and a half hours' test below full load the temperature was nearly 120° C. Mr. Hodgkin did not think 120° C. too high a temperature for enclosed motors insulated with cotton. The motor in question was insulated with asbestos. The specification said clearly that the plaintiffs should have nothing to do with the pumps after they were handed over to the defendants, and witness claimed that they were handed over before they were started working continuously. The pumps were returned in a very bad condition, the efficiency had fallen from 75 to 25 per cent., which meant that both generators and motors would have to sustain a much heavier load for the same amount of water raised. Mr. W. C. Mountain, Director of plaintiff company, said that he was quite satisfied that the plant was capable of doing the work specified if it were properly looked after. It was absolutely necessary that there should be a relief pump in work of that character, as the motors should have been overhauled every 24 hours, which overhauling would take a man from one to one and a half hours. Mr. Mountain said that, with regard to the testing, it was the defendants' duty to call upon the plaintiffs to make a test of the plant before their expert. Such a test was arranged for, but was never held. The plant had been started up, owing to the impatience of the defendants' directors, before the motor coils had been dried out. The motors were perfectly dry before being installed in the shaft, and were tested at plaintiffs' works with 10,000-volt alternating current. He denied that the machines were insulated in the first place with damp cotton. The insulation was not impregnated, as the machines were too large to allow of this. The process of impregnation, said Mr. Mountain, was only applicable to small machines. Varnished cotton insulation (which was used for one motor) was not absolutely impervious to damp. With regard to temperature, Mr. Mountain thought that 150° C. was not too high for an asbestos winding. Mr. John Morley, foreman engineer for the plaintiffs, gave corroborative evidence, and the hearing was then adjourned until the 29th inst.

LOCAL NOTES

ABERDEEN: *Parliamentary Expenses.*—An account has been presented of the Parliamentary expenses in connection with the Corporation Electricity Act of 1907 and the Corporation Order Confirmation Act, 1907. The expenses with regard to the former amounted to £2,122, and for the latter £1,278. The payment of these is to be spread over five years.

AUSTRALIA: *Sydney: Lighting Accounts.*—The electric lighting undertaking shows a loss of £1,308 for the year 1907. For 1906 the loss was £9,552.

BANGOR: *Telephone Wayleaves.*—In consequence of having received an intimation from the Urban District Council that an increased rent must be paid for their poles, the National Telephone Co. have refused to accede to the proposed terms, and intimate that, if the Council insists, it will be necessary for the company to discontinue its service in Bangor. The matter has been referred to the Finance Committee of the Council.

BERMUDA: *Electric Supply.*—The Bermuda Electric Light, Power, and Traction Co. announces that it will be in a position to supply electric current on May 1st.

BRIGHTON: *Electric Lighting Charges.*—A change is to be made in the electric lighting tariff now in vogue. Consumers upon the maximum demand system of 7d. for the first hour and 1d. afterwards will in future be charged 6d. and 2d. respectively. The flat rate of 4d. will remain. It is stated that there will also be an increase in the charge for street lighting.

Southwick Electricity Works.—The Works Committee of the Shoreham Harbour Trustees dissents from the view of the Corporation that the works carried out near the Southwick Electricity Station are sufficient for the protection of the foreshore of the harbour at that spot. The Harbour Master's report on the subject reads as follows: "With reference to the portion of the foreshore fronting the Electricity Works, I find that the work which has been done by the Corporation of Brighton consists of a line of piling and planking about 130 ft. long lying parallel with the foreshore and through the crown of the beach. The western end of the work is about 20 ft. short of the western boundary of the Corporation's land, but I am informed that the work will be extended to that point. The work consists of 7 in. by 7 in. piles 8 ft. 6 in. long, driven about 6 ft. into the beach, 9 ft. 6 in. apart from centre to centre, and planked on the sea side 3 ft. down from the top with 3 in. by 9 in. planks. This work, although being sufficient to merely support the material which is being deposited on the north side of it for filling-in purposes, is not, in my opinion, sufficient to withstand the force of sea which would reach it during a southerly gale at high spring tide. There are, however, indications that the beach is again accumulating at this part of the foreshore."

BURNLEY: *Electric Power Charges.*—The Corporation announce this week a reduction in the price of electricity. Electrical energy for power and heating purposes will be reduced to 1½d. per unit for the first 39 hours per quarter, calculated on

Digitized by Google

the consumer's maximum demand, and a 1d. per unit afterwards during the same quarter. Moreover, quarterly accounts will be subject to a 5 per cent. discount for prompt payment.

BURSLEM: *Electricity Accounts.*—The accounts of the Electricity Department for the year ending December 31st, 1907, show an income of £3,261, and expenditure £1,223. Of this gross profit, interest on loans absorbs £1,002, and sinking fund £800, leaving a net profit of £202. Expenditure on capital account during the year was £5,918, making a total capital expenditure of £52,397.

CANADA: *Telephone Purchase.*—A Bill has been introduced into the Ontario Legislature providing that, where the majority of subscribers in a district petition for the establishment or extension of a telephone system, the municipality can issue debentures for ten years to cover the cost of the work, and to levy a special rate to pay the annual instalments of principal and interest. Any deficiency may be made up out of the rates.

CHICHESTER: *Electric Lighting.*—A site has been secured at Stockbridge by the Chichester Electric Lighting Co. for its works.

COWDENBEATH: *Electric Lighting.*—The Manager of the Fife Electric Power Co. has had a conference with the Town Council with regard to the supply of electricity to the borough, and a report is to be drawn up by the company and presented to the Council at an early date.

DERBY: *New Power Station.*—The new electricity works of the Derby Corporation, which were described and illustrated in Electrical Engineering, Vol. II., 979, were formally opened last week by the Mayor, who started one of the new steam turbines, and Alderman Butterworth, Chairman of the Electricity Committee, who started the second turbine.

DURHAM: *Electricity in Coal Mines.*—A start has been made with the work of the New Winning East Pit, Lumley Colliery, near Chester-le-Street. It is stated that this will be the only coal mine in the world which will be worked entirely by electricity—all winding, pumping, hauling, screening, coal cutting, and lighting being carried out electrically.

EALING: *Noisy Tramcars.*—In connection with the action which the Council proposes to institute against the London United Tramways, Ltd., for an injunction in respect of alleged nuisance caused by the noise of the tramcars, the Chiswick Urban District Council has agreed to contribute a sum not exceeding £60 towards the cost of the action.

EDINBURGH: *Underground Telegraph Wires.*—The Secretary of the Chamber of Commerce has received a communication from the Postmaster-General in response to inquiries as to the progress of underground cable work in Scotland during 1907. The letter from the Postmaster-General points out that it is hoped within a few weeks' time to complete the line from Glasgow to Falkirk. The underground line from Linlithgow to Edinburgh, the letter states, would have been completed long since but for the difficulties which have been experienced in obtaining from the Corporation of Edinburgh the necessary consents to the execution of the underground work required in the streets of Edinburgh. An arrangement may probably be arrived at, but as this involves the use of existing ducts, so small that the size of the cable has had to be reduced, it may be necessary to duplicate the work later on.

Leith Tramways.—An amicable arrangement has been come to with regard to the points of difference between the Edinburgh Corporation and the Leith Town Council in regard to the proposed extension of the Leith tramways to Granton.

FLEETWOOD: *Transfer of Electrical Undertaking.*—An agreement has been come to between the Council and the Fleetwood & District Electric Light & Power Co. for the purchase of the undertaking of the latter at £16,000 for the works, and £2,500 for the site.

GLASGOW: *Assessment of Telephone Wires.*—A dispute has arisen between the Postmaster-General and the Glasgow Corporation with regard to the amount of the assessment upon the telephone undertaking acquired from the Corporation. Prior to the taking over of the undertaking by the Postmaster-General, the Telephone Department paid assessment amounting to £1,690, but the Post Office now raise objection to the amount. The Police Finance Committee of the Corporation recommend that a representation be made to the Treasury in order to secure payment.

HAMPTON WICK: *Noisy Tramcars.*—At the last meeting of the Council, the Highways Committee reported the receipt of a letter from the Commissioner of Police, stating that the result of careful inquiry showed the source of the noise from the tramcars was to be found not in the cars (which were kept in good condition), but in the track, which was very defective, so much so that in places the wheels came in contact with the wood blocks or stone setts. A copy of the Commissioners' letter as to the noise of the trams is to be sent to the Board of Trade, and the Borough Surveyor is to report to the committee on the subject in due course.

HANDSWORTH: *Tramway Purchase.*—The Board of Trade has been asked to appoint a referee to determine the price to be paid by the Council for the tramway company's undertaking in Handsworth. If an agreement cannot be come to upon the terms of the subsequent lease, the referee is to consider this matter also

HANWELL: *Transfer of Electric Lighting Order.*—The Metropolitan Electric Supply Co. intimates its willingness to take over the Council's electric lighting order for £550. The consulting engineer to the Council recommends that the company should also pay the interest on the money borrowed for the purposes of obtaining the order, viz., about £40, and he is in communication with the company upon this point.

INCE: *Electric Lighting Order.*—An agreement has been come to between the District Council and the Wigan Corporation with regard to carrying out the terms of the Council's Electric Lighting Order.

LAUNCESTON (TASMANIA): *Electricity Accounts.*—The report of the City Electrical Engineer for the year 1907 states that the expenditure on capital account during the year amounted to £3,353. Of this amount £648 was part of balance due to the contractors for three-phase plant, £944 for meters, construction work on mains, consumers' connections, &c., the balance being for general stores and private wiring, after allowing for repayments to the department for work done. The total expenditure to December 31st, 1907, is £164,196, including £2,825 value of stock on hand. The number of consumers is 3,175. An expenditure of £11,663 on consumers' meters has been incurred. A sum of £30,000 has been spent on the change over from single-phase to three-phase working. The report points out that when single-phase was wholly in use, the earnings from power were only £537. During 1907 the revenue from this source was £1,835, an increase of £1,298; leaving, after deducting increased maintenance charges, a net increase of £1,201. The total revenue for the year was £16,286, as against £14,934 for 1906. The increase in revenue from lighting is 2·86 per cent. over last year; the increase in revenue from power is 67·43 per cent., and from heating 20·05 per cent. The expenditure for the year shows an increase of £910. The revenue from street lighting was £2,434 for 357,878 units, equal to 1·633d. per unit. In 1895 the city was lighted by 274 gas lamps at £5 7s. 6d. each per annum = £1,473 15s. There are now 432 incandescent lamps and 175 arc lamps. The balance carried to net revenue account is £8,770, an increase of £375. Interest and contributions to sinking funds have increased by £135, leaving an actual surplus on the year's working of £1,557. The sinking and reserve funds now amount to £23,518. The gross profits since the commencement of the undertaking have been £66,070. During the year under review the units generated were 1,722,380; units used at power station, 17,000; units lost in transmission, 127,820; units supplied from sub-station, 1,577,560; units accounted for, 1,330,140; units lost in mains, transformers, meters, &c., 247,420. The total costs have decreased by 0·211d., or 12·7 per unit sold. The maximum load was 680 kw. Several new types of lamps have been obtained and tested during the year. The best of these are the "Osram" and the "Tungsten." Unfortunately at the present the filament of the former, being of a fragile nature, does not carry well in transit; the "Tungsten" filament, however, seems to be of a tougher nature, and the results on opening up the shipments are more satisfactory in this respect. The Corporation have obtained a few of these lamps, and they are available to the public at cost price, or are supplied free on the usual basis of lamp renewals to an equivalent in money value. The tests made so far show that the lamp maintains its original candle-power to within a few per cent. after about 1,000 hours' burning.

LIVERPOOL: *Motor Generators.*—At the last meeting of the Liverpool City Council a question was asked as to why the tender of the British Westinghouse Electric and Manufacturing Co. for the supply of a 500-kw. and 200-kw. motor generators was accepted. Sir C. Petrie, Chairman of the Tramways Committee, stated that the tender in question was the lowest, and in view of the fact that the Westinghouse turbines at the Lister Grove station had been working satisfactorily the Committee felt justified in accepting the tender.

LONDON: *London County Council. Highgate Hill Tramways.*—At the meeting on Tuesday the Council agreed to purchase for £13,000 the Highgate Hill cable tramways. About £26,000 is to be spent on electrifying the line (see Electrical Engineering, April 9, p. 574).

Hammersmith-Putney Tramways.—The report of the Highways Committee given on p. 596 was adopted.

Electric Lighting Loans.—The Finance Committee have submitted a statement to the Council showing the amount sanctioned during the financial year 1907–8 and the three preceding years. The following are the items in respect of electric lighting:—1904–5, £749,109; 1905–6, £319,119; 1906–7, £282,760; 1907–8, £272,518. The amount for the year 1904–5 does not include anything in respect of the loan of £1,415,000 made to the St. Marylebone Borough Council on July 26th, 1904, for the purchase of part of the undertaking of the Metropolitan Electric Supply Co., Ltd., as the Act authorising the Borough Council to make the purchase dispensed with the sanction of the London County Council to the borrowing.

Lea Bridge, Leyton and Walthamstow Tramways.—The London County Council propose to hold a special meeting soon after Easter to discuss the question of purchasing, by agreement, the portion of the Lea Bridge, Leyton and Walthamstow Tramways Co.'s undertaking in the Lea Bridge Road.

Digitized by Google

Great Northern, Piccadilly & Brompton Railway.—The Council has approved a plan of the exits and entrances at the street level of the station to be erected on the Great Northern, Piccadilly & Brompton Railway at South Kensington (Pelham Street). As these plans differ somewhat from the original ones submitted by the company, the Council has accepted a sum of £500 towards the cost of effecting a street widening opposite the station, rendered necessary by the construction of the exits and entrances nearer the footway than was originally contemplated.

Franco-British Exhibition.—The Council has approved the plan of the exits and entrances at the street level of the Central London Railway Co.'s proposed station at Wood Lane, Hammersmith, which is intended to serve the Franco-British Exhibition. The frontage of the station will be set back 15 ft. from the edge of the kerb, and three entrances and two exits will be provided.

Fulham: Electrical Development.—A canvasser for power and lighting purposes is to be appointed at a salary of £2 per week and commission.

Hammersmith: Tramways.—The Law and Parliamentary Committee, being of opinion that a double tramway line over Hammersmith Bridge would be dangerous, has decided to oppose the West London, Barnes and Richmond Tramways Bill. The same committee has decided that notice be served upon the London United Tramways, Ltd., requiring them to forthwith make good the defective joints in the tramway rails, and to take up and relay with new wood blocks the paving inside the tramway rails throughout the whole length of Goldhawk Road and Uxbridge Road in the borough.

Marylebone: Electric Lighting Loan.—The Council has decided to take up a loan of £31,306 for electric lighting purposes at 4 per cent. from the London County Council, repayable in 30 years.

St. Pancras: Stock Checking.—Negotiations have been entered into with several firms of valuers, with the result that an offer has been accepted from Messrs. Bromhead & Co., 33 Cannon Street, E.C., to make a thorough and detailed schedule of the stores in hands for balance-sheet purposes, and to check and price same, and supply the inventory as required for 35 guineas on the understanding that if engaged for more than one year they will only charge 25 guineas next year, so as to bring their fee to 30 guineas per annum, at which rate they are prepared to do the work in subsequent years.

Street Lamps.—The Chief Electrical Engineer having received from the Borough Engineer an inquiry as to the probable cost of shifting all the arc lamps in the Tottenham Court Road from the centre of the roadway to the pavement, in view of the asphalting of the thoroughfare, the former reports that the proposal would involve five additional lamps. There would be, he said, considerable difficulty to be surmounted, inasmuch as pretty nearly throughout the Tottenham Court-road the cellars come very near the surface, and consequently the small space left is choked with electric, telegraph, telephone, gas, water, and hydraulic mains. The estimated cost of increasing the length of the circuits from the centre of the road to the side, in every case shifting the existing posts and supplying and erecting five new lamps and columns, is £350, and, in addition to this capital expenditure, there would be a permanent revenue charge for the maintenance of the five lamps of about £87 per annum. The electricity committee strongly disapprove of the proposed alteration of centre lighting to side lighting, on the ground that experience proves that the centre lighting is more advantageous from an illumination point of view.

Westminster: Street Boxes.—The City Council Works Committee have had before them the views of the Westminster Electric Supply Corporation with reference to the committee's consent to the laying of mains and boxes in four thoroughfares, subject, *inter alia*, to the proposed boxes being ventilated by combined ventilating covers instead of by separate gratings. The company stated that very great care is taken to render the boxes watertight, that ventilation is essential, and the difficulty is to combine this with keeping the boxes clean and dry; that hitherto they have used small ventilating boxes connected to the main boxes by a pipe; that the little boxes with a grating on top are placed as close to the house front as possible, and after rain all that is necessary is to lift the grating and dry them, an operation which takes a few minutes only. After negotiations, the Council's Works Committee has decided to agree to the use of separate pits of the existing pattern for ventilating street boxes, provided each pit be placed as close as possible to the box itself, and, wherever practicable, over the line of the company's wires.

LONGTON: *Street Lighting.*—It has been decided to replace 41 gas lamps by 18 arc lamps for the street lighting. The capital cost will be £385, and the annual charges in respect of current, trimming, cleaning, attendance, &c., £504. The lamps will be run in two circuits of nine lamps each, and every alternate lamp is to be switched off at 11.15 p.m.

MANCHESTER: *Tramways Undertaking.*—The estimates of income from the tramways undertaking from the present financial year is £813,662. Capital expenditure for the year is estimated at £78,000, mainly on new cars, sheds, &c.

NEWCASTLE: *Cables under the Tyne.*—An application from the Newcastle Electric Supply Co. for permission to lay a 6,000-volt, three-core, lead-covered cable across the bed and foreshore of the Tyne between Carville, Wallsend, and Hebburn has been granted, but owing to the uncertainty of the date when the tunnel works will be completed, permission has also been granted to regard the works as a temporary works on the condition that the company exhibits a board indicating where the electric cables are on either bank of the river.

NEWPORT, MON.: *Tramway Depreciation.*—The Electricity and Tramways Committee recommend that before any surplus on tramway revenue account is applied in relief of rates, a sum averaging £3,000 per annum should be paid into the tramways reserve fund.

NUNEATON: *Street Lighting.*—In connection with the renewal of the Gas Co.'s contract for street lighting, the Electricity Committee endeavoured to secure the substitution of electricity for gas, but the Council decided that it would be unwise to make the change at present, owing to electricity being still "in its infancy," and new lamps being continually brought out.

OXFORD: *The Tramway Question.*—At the last meeting of the Corporation Councillor Hastings moved a resolution calling for a detailed statement of the whole of the legal and professional charges incurred in the purchase of the horse tramway system, the special arbitration case, and the contract for the construction and electrification of the new tramways. The Council went into committee on the question, and it was ultimately stated that the resolution was lost.

PEMBROKE: *Electric Supply Charges.*—The Electrical Engineer has been instructed to prepare a report upon a revision of the present system of charging for electrical energy for cooking and heating purposes.

PENZANCE: *The Electric Lighting Order.*—The Penzance & District Electric Supply Co. has been notified by the Board of Trade that the consideration of the question of revoking the company's order has been deferred to October 31st.

ROTHERHAM: *Tramway Receipts.*—The receipts from the tramway undertaking for the year ended March 31st, 1908, amount to £31,678, as against £26,916 for the previous year.

SHEFFIELD: *Tramway Extensions.*—According to the *Sheffield Telegraph*, a number of important tramway extensions are to be completed during the coming summer months. Work is at present proceeding upon the Hillsborough-Malin Bridge section, the permanent way of which is expected to be completed soon after Easter. Later on the Eccleshall extension will be put in hand.

TORQUAY: *Tramway Supply.*—With regard to the application of the Tramway Company for an increased maximum supply for working the tramways, Messrs. Kincaid, Waller, Manville & Dawson have reported to the Council as to the ways and means for complying with this request. The generating station at present does not permit of the addition of further plant, and the report recommends that the power-house should be wholly, or partially, removed to a larger site adjoining the dust-destructor works. This would involve the use of a cooling tower, as the site in question would prevent the use of sea-water for condensing purposes. Two alternative schemes have been presented, one of which involves the complete transfer of the plant and housing it in new buildings, and the second provides for the transfer of a portion of the plant, leaving the remainder as at present. The respective estimates are £29,390 and £16,000. At the last meeting of the Corporation the matter was referred to the Electric Lighting Committee for a report. There was a good deal of criticism of the reports of the consulting engineers, some members of the Council apparently being convinced that it is possible to instal the additional plant necessary on the present site. The estimates of the consulting engineers are based upon the consumption of 1,107,364 units by the tramway company during 1908, of which 659,065 units would be for traction purposes, and the remainder for lighting.

WATFORD: *The Electrical Engineer.*—The Council has decided to give the electrical engineer, Mr. J. R. Weston, notice terminating his engagement in consequence of his having engaged a temporary draughtsman without the sanction either of the Electricity Committee or the Council.

WEALDSTONE: *Electric Lighting.*—Under the Wealdstone Electric Lighting Provisional Order, 1906, the North Metropolitan Electric Power Distribution Co., Ltd., is bound to lay mains in the compulsory area within two years from July 20th, 1906. At the last meeting of the Council the Finance Committee drew attention to the fact that no work has yet been commenced by the company, nor were the committee aware that any were contemplated. It was ultimately decided that the Council could not interfere until the time has expired.

WEST HAM: *New Chain Grate Stokers.*—The Electrical Engineer having reported that it was necessary to proceed with the erection of two of the five chain grate stokers at the generating station, included in his estimate of £51,600, the Committee have decided in favour of his being empowered to proceed with this work at an estimated cost of £700.

Tramways.—The Town Clerk has reported to the Committee that a writ has been issued against the Corporation at the instance of Mr. F. Osman, the contractor for the construction of the tramways, for the recovery of £615 under an agreement for laying metallic returns from the Canning Town station to the end of the double track in Barking Road, and also for damages for breach of the contract entered into with the Corporation as to the laying of certain tramways in West

Digitized by Google

Ham, and for delay on the part of the Corporation in permitting him to commence the work. After careful consideration, the Committee, desiring to avoid litigation, have settled the claim, subject to the Council's confirmation, at £2,000, and a sum not exceeding £50 for costs.

WESTON-SUPER-MARE: *Street Lighting.*—The Local Electric Supply Co. has been granted permission to carry out some experimental electric lighting on the sea front.

WILLESDEN: *Harrow Road-Paddington Tramways.*—Subject to the Metropolitan Electric Tramways, Ltd., agreeing to do their utmost to expedite the widenings remaining to be carried out in connection with the Harrow Road and Paddington tramways, a three months' extension of time from May 6th, 1908, is to be granted them for performing the condition of a bond. This bond was entered into in December, 1906, in the sum of £25,000, to be paid to the Council in the event of certain widenings not being satisfactorily completed within a period of 18 months from November 6th, 1906, or within such extended period not exceeding six calender months, as, having regard to causes beyond the control of the company, should be necessary for such completion. The Council has decided not to further oppose the Metropolitan Electric Tramways Bill, 1908.

TENDERS INVITED AND PROSPECTIVE BUSINESS

ABERDEEN.—The Electricity Committee recommend that application be made for sanction to borrow £80,000 for extensions to the electricity undertaking, out of which sum the purchase of the Cults electricity undertaking will be made. The recommendation was adopted at the last meeting of the Corporation.

AMSTERDAM.—A concession has been granted to the Amsterdam and North Holland Electric Tramways Co. for a tramway from Amsterdam to Krommenie and two branch lines from Zaandyk to Wyk aan Zee, and from Wormerveer to Purmerend. The total length of the lines will be about 28 miles, and the work has to be completed within two years.

ARRAN.—The Marquis of Graham has instructed Messrs. Stevenson & McGuffie to draw up specifications for an electric light and power installation at his two residences and the estate offices in Arran. A water power scheme is in contemplation, using pelton wheels and a transmission line of about 12 miles in length will be involved.

ASTON.—Mr. R. H. Bicknell held an inquiry last week into the application by the Council to borrow £25,213 for the electricity undertaking. The capital expenditure upon the undertaking to date amounts to £134,466. Part of the loan now sought is in connection with the supply in Erdington, for which powers were obtained last session. It is estimated that the maximum demand during the next winter will amount to 2,156 kilowatts, whereas the plant capacity is only 1,708 kws.

CANTERBURY.—A local Government Board inquiry was held last week into an application by the Corporation to borrow £4,000 for electric lighting extensions.

DUNDEE.—Tenders are invited for the following:—(*a*) steam, exhaust, feed water, and drain piping system, with two steam-driven feed pumps and two hotwell tanks for main generating station; (*b*) equipment of circulating water pump room, including two electrically-driven vertical-spindle centrifugal pumps, in connection with the main generating station; (*c*) circulating water-pipe system (about 1,500 feet long), in connection with the main generating station; (*d*) overhead travelling cranes for main generating station and two sub-stations. Full particulars from the City Electrical Engineer, fee £3 3s., returnable, and tenders to the Town Clerk by April 27th.

GOVAN.—Tenders are invited for the supply of the following stores for the year ending May 15th, 1909: Oil, waste, and engine-room stores; cables; cable accessories; bitumen and compound for joint boxes; electricity meters; house service fuse boxes; wrought-iron tubes and fittings; cast-iron pipes; arc lamp carbons; coal; joint boxes; motors; motor starters and D.P. switches. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by April 27th.

HASLINGDON.—Tenders are invited for overhead tramway lines with tangential suspension, telephone system, and tower wagon. Particulars from the consulting engineers, Messrs. Handcock & Dykes, 1 Victoria Street, Westminster (fee, three guineas, returnable), and tenders to the Town Clerk by April 25th.

HORNSEY.—Tenders are invited for the supply of cable, feeder pillar joint boxes, &c., in connection with a new feeder cable to Muswell Hill. Forms of tender, &c., from the Borough Electrical Engineer (fee, 10s. 6d., returnable), and tenders to the Town Clerk by April 21st.

ITALY.—The *Bulletin* of the French Chamber of Commerce at Milan, for March, announces that the Rome municipality intend to instal a generating works having a capacity of 7,000 h.p.

LANCASHIRE.—Messrs. Pearson & Knowles Coal & Iron Co., Ltd., contemplate an expenditure of about £40,000 upon an electrical installation and new screening plant at their Maypole Colliery, Abram, near Wigan.

LONDON: *London County Council.*—Tenders are invited for the wiring and fitting for electric lighting of a tramway car shed at Mare Street, Hackney. Particulars from the Clerk, fee £2 2s., returnable, and tenders by May 12th. (See an official advertisement.)

Tenders are invited for the supply and delivery of (*a*) 175 double-deck, roof-covered, electric car-bodies; (*b*) 175 pairs of maximum traction swing bolster trucks; (*c*) 175 complete electrical equipments for operation upon the overhead trolley, surface contact, and underground conduit systems of electric traction. Full particulars from the Clerk to the Council (fee £2 2s. returnable), and tenders by May 9th.

The Highways Committee recommend that an expenditure on capital account not exceeding £31,000 be sanctioned for the execution of the road work and platelaying, exclusive of the supply of rails and special track work, on the conduit system, of the existing horse tramways from Lavender Hill via Queen's Road, Battersea, to Chelsea Bridge.

Hammersmith.—The Electricity and Lighting Committee have had under consideration the question of converting the system of lighting the streets in the borough from gas to electric lighting, in which the necessary low-tension mains have already been laid for private supply. Sixty-eight streets are affected by the proposal, and the Engineer has submitted a report showing that in these streets electricity giving a greater candle-power could profitably be substituted for the present gas supply at the same rate of charge, viz., £3 1s. per lamp per annum. No capital expenditure will be incurred in laying mains, as the suggested scheme provides for the use of the existing low-tension mains only, and it is proposed to purchase the present gas columns. The Committee proposes to take over the streets along which low-tension mains are laid, and supply a 44 candle-power electric lamp in substitution for the 30 candle-power gas lamp.

Hampstead.—The Borough Council is to lay a main for the supply of electric current to private consumers at an estimated cost of £41. The Electrical Engineer has been authorised to obtain meters and other stores at an estimated cost of £48 11s. 9d.

Poplar.—The Electricity Committee invite tenders for the erection of a sub-station building at Millwall in brick, ferro-concrete, or corrugated iron. Full particulars from the Borough Electrical Engineer, fee 5s., not returnable, and tenders to the Town Clerk by April 29th.

MORLEY.—For the purpose of providing additional plant in connection with the tramways an application is to be made to the Local Government Board for sanction to borrow £7,942. A further sum of £5,000 is to be borrowed for new cables.

SPAIN.—The *Gaceta de Madrid* of March 18th notifies that the Compania General de Tranvias has applied for a concession for an electric tramway in Barcelona, and that a period of one month is allowed for the presentation at the Direccion General de Obras Publicas, Madrid, of competitive propositions.

TONBRIDGE.—The Council invite tenders for the supply and erection of the following plant: Section A.—One 150-kw. high-speed steam generating set with ejector condenser. Section B.—Steam feed pump, 700 gallons per hour. Centrifugal Motor-driven pump, 20,000 gallons per hour. Steam, exhaust, feed, and water piping. Section C.—Two switchboard panels, milking booster and switchgear, cables and connections. Specifications, &c., from the Electrical Engineer (fee £1 per section returnable), and tenders to the Town Clerk by April 22nd.

WHITEHAVEN.—The Corporation is recommended to apply to the Local Government Board for sanction to borrow £1,700 for a surface condensing plant, battery, switchboard, and booster, extensions of mains, and auxiliary plant at the electricity works.

WIGAN.—An application is to be made to the Local Government Board for sanction to borrow £22,696 to cover expenditure on capital account, in addition to committments during the coming year.

WILLESDEN.—The Electrical Engineer has been instructed to prepare the necessary specifications and advertise for tenders for the installation of additional plant at an estimated cost of £1,500 at the Salusbury Road sub-station, in order to cope with the increased demands of the district. An additional feeder cable is to be laid from the Salusbury Road sub-station at an estimated cost of £2,070, to relieve the present overload on the High Road, Kilburn, feeder, and mains are to be extended in Furness Road at an estimated cost of £62. The Council has approved the action of the chairman of the Electricity Committee authorising extension of mains in St. Gabriel's Road (estimated cost, £31) and Teignmouth Road (estimated cost, £17 10s.).

WOOD GREEN.—Messrs. May & Hawes have been retained to advise on the electrical work for the new infirmary. An offer has been received from the North Metropolitan Electric Power Supply Co.

YORK.—A Local Government Board inquiry was held on Tuesday into an application by the Corporation for sanction to borrow £25,285 for the purpose of the electricity undertaking.

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

BECKENHAM.—It was stated at the last meeting of the Beckenham Urban District Council that the superintendent of the Fire Brigade had reported that the present system of fire alarms gave rise to many unnecessary calls, and that tenders had been submitted for an improved system known as the "Stuart and Moore Pendulum" system. The Council decided in favour of acceptance of the National Telephone Co.'s tender to fix this system in Beckenham at an annual charge of £180. It was pointed out that the annual rent paid for the existing system, including daily testing, was £172. The only other tender was that of the G.P.O., for what was known as the "Buzzer" system, with street posts and overhead wires, at £152 per annum, to which the superintendent estimated that £26 should be added as the cost of testing, and £10 for the rent of an exchange, making a total of £188.

BRIERFIELD.—The Brierfield District Council has accepted the tender of Messrs. Carter & Co., of Nelson, for the maintenance of fire-alarms in the district during the year ending March 31st, 1909.

ELECTRIC POWER IN STEEL WORKS.—Messrs. Marples, Leach & Co. advise us that they have been successful in securing the order for the supply, delivery, and erection of a high-tension two-phase alternating-current induction motor for driving two 10 in. and 8 in. mills at the works of Messrs. Samuel Osborn & Co., Ltd., Sheffield. This motor is being wound for the high-pressure distributing mains of the Sheffield Corporation Electric Supply Department at 2,000 volts, two phase, 50 cycles. The motor is normally rated at 350 b.h.p., but is capable of sustaining very considerable overloads for short periods without injury; it is being provided with wound rotor, brush lifting, and short-circuiting device, by means of which the wear and tear on the brushes and slip rings is reduced to a minimum. In order to enable the fly-wheels to take their proper share of the work, the rotor is being provided with a bank of resistances which rotate with the machine, thus allowing a considerable percentage of slip when the load exceeds the normal. This motor is the largest motor which has yet been placed upon these mains, and it is anticipated that very great economy will result in the working of the mill.

ERITH.—The Council has accepted the tender of George Wright, Ltd., at £7 13s. 6d., for the supply and fixing (exclusive of builders' work) of a collapsible steel gate (8 ft. by 8 ft.) for the Northumberland Heath tramway shelter.

The Council has also accepted the following tenders for annual supplies of stores to the electricity department:—Oils, W. H. Wilcox; gauge glasses, W. H. Wilcox; carbons, Veritys, Ltd.; meters, General Electric Co., Ltd.; incandescent lamps, Veritys, Ltd.; joint boxes, Callender's Cable & Construction Co., Ltd.; cut-outs, British Insulated & Helsby Cables, Ltd. With regard to tenders for cables, &c., the Electrical Engineer is to obtain samples from several of the lowest tenderers and report thereon to the Electric Lighting and Tramways Committee.

GREAT EASTERN RAILWAY.—An order for 10 "Cascade" induction motors for driving printing presses has been placed with the Sandycroft Foundry Co., Ltd.

HEYWOOD.—The following tenders have been accepted:—Section A: Boiler, &c., Messrs. Thomas Hill & Sons, £1,605; Section B: Engine, dynamo, condensors, &c., Messrs. Browett, Lindley & Co., Ltd.; Section C: Lighting switchboard, Messrs. Whipp & Bourne, £827; tram feeder cable, British Insulated & Helsby Cable Co., Ltd. The Heywood Electricity Committee have also instructed the Borough Engineer to prepare specifications and quantities for the extensions (buildings and foundations) at the electricity works.

ILFORD.—The following contracts have been entered into for the ensuing year:—Cables, W. T. Henley's, Ltd.; coal, Dinham, Fawcus & Co., Ltd., E. Foster & Co., Ltd., Lindsay Blee & Co., Ltd.; house service and fuse boxes, General Electric Co., Ltd.; incandescent lamps, Cryselco Electric Lamp Co., Ltd.; joint boxes, W. Lucy and Co., Ltd.; meters, Ferranti, Ltd., and Siemens Bros. Dynamo Works, Ltd.

LONDON: *London County Council.*—The following tenders have been received for shafting, pulleys, &c., for the first portion of the central car depôt in Woolwich Road:—Forced Lubrication Co., Ltd., £400 3s. 2d.; Smith & Grace Screw Boss Pulley Co., Ltd., £453 17s. 8d.; David Bridge & Co., Ltd., £485 13s. 7d. and £466 15s. 2d.; The Unbreakable Pulley & Millgearing Co., Ltd., £553 2s. 3d. and £556 12s. 6d.; Buck and Hickman, Ltd., £572 1s. 3d. and £546 7s. 8d. The Highways Committee recommend the acceptance of the tender of the Forced Lubrication Co. at £400 3s. 2d. The Highways Committee also recommend the acceptance of the tender of Messrs. H. W. Ward & Co., at £103 14s. 9d., for accessories for a 7½ inch capstan lathe at the same depôt.

The Highways Committee further recommend the acceptance of an offer by Messrs. Hadfield's Steel Foundry Co. to undertake, for a sum of £4,524 10s., the manufacture and delivery of the special trackwork required for the renewal of the permanent way of portions of the tramway track in Westminster Bridge Road, Kennington, Clapham, Old Kent Road, and Camberwell Green. The tramways in question were among the first to be constructed by the Council for electric traction, and electric car services have been in operation since May, 1903, and January, 1904.

The following tenders have been accepted in connection with the construction of 20 new car bodies by the Tramways Department, of car furniture, brake and sanding gear, window operating gear, and ventilator operating gear:—Hurst, Nelson & Co., car furniture, £369 0s. 9d.; United Electric Car Co., 50 sets of brake gear at £4 19s. per set; Hurst, Nelson & Co., 50 sets of sanding gear, movable steps, and life-guards, at £8 2s. 6d., £3 12s. 6d., and £4 5s. a set respectively, and 50 sets of window operating gear at £12 10s. a set; Hoskins & Sewell, Ltd., 50 sets of ventilator operating gear at £3 a set. The tender of Messrs. Hurst, Nelson & Co., for the supply of 400 sunblinds for the 50 car bodies referred to, and a further 18 for maintenance purposes at £292 10s., has also been accepted.

As the result of a careful examination it has been found that certain of the plates of the battery at the Victoria Embankment generating station have deteriorated, and the Highways Committee recommend that an offer by the Electrical Power Storage Co., who supplied the battery, to carry out the necessary repairs for £130, should be accepted.

Fulham.—The Borough Council has accepted the following tenders for annual supplies for the electricity department:—General Electric Co., Ltd., fuse wire, &c.; G. A. Pestalozzi & Co., carbons; Lucy & Co., house cut-outs; Duckham & Co., Ltd., cylinder oil; W. H. Wilcox & Co., Ltd., crank chamber oil; H. Edmonds & Co., packings, &c.

Hammersmith.—The Electricity and Lighting Committee has accepted the tender of the Main Colliery Co. for the supply of Graigola and Victoria coal, at 15s. 10d., for a period of three months, with the option of continuing the contract for a further nine months.

Marylebone.—The following tenders have been accepted for stores for the electricity undertaking: Edison & Swan, Ltd., cut-outs and switch blocks; W. McGooch & Co., Ltd., pear switches; Wm. Patterson, dynamo brushes, brass wire brushes, copper gauze brushes, copper tinsel brushes; Reason Manufacturing Co., Ltd., house service meters; Chamberlain and Hookham, Ltd., prepayment meters.

TYNESIDE.—An order has been placed with the British Thomson-Houston Co., by the Tyneside Electrical Developments Co., for an exhaust steam turbine, having an output of 1,500 k.v.a. at 2,875 volts, 40 cycles, at a speed of 2,400 revs. per min. This machine will work in connection with the Tees Bridge Iron Co. We give further particulars in a note on page 588.

WORCESTER.—The tender of Messrs. J. Wood & Sons, Ltd., for extensions to the pump-house at the Hylton Road station has been accepted at £149 10s.

COMPANIES' MEETINGS AND REPORTS

ANGLO-ARGENTINE TRAMWAYS.—At the annual general meeting on Thursday the report and accounts given in our issue for April 2nd were adopted. Mr. J. Concanon, the chairman, who presided, dealing with the prospects of the undertaking, said that he thought the profits for the year 1908 would show a considerable increase. Up to April 1st the gross receipts showed an increase of £30,742. With regard to the financial stability of the company, he mentioned that the balance standing to the credit of the paving depreciation fund, and the general depreciation renewals fund, was £215,979. With a view to ascertaining more closely the figure which should in future be charged annually to revenue under this head, an exhaustive examination of the question would be made towards the end of the year. The directors propose to make an issue of £500,000 new debentures very shortly, £200,000 of which would be applied to meeting additional capital expenditure for increased rolling stock, &c., and the remaining £300,000 to the purchase of £300,000 of La Capital Traction & Electric Co., of Buenos

Digitized by Google

Aires 5 per cent. debentures. This might be regarded, the Chairman said, as a step towards the acquisition of other tramway undertakings.

BALAGHAT GOLD MINING.—Lord Ribblesdale, presiding at the annual meeting last week, called attention to the fact that the cost of electrical power supplied from the Cauvery Falls power scheme had been reduced from £24 to £10 per horse-power per annum, a reduction which would, he said, result in a saving to the company of £7,770 per annum.

BATH ELECTRIC TRAMWAYS.—The report and accounts to December 31st, 1907, states that owing to the condition of the money market during the greater part of the past year the extension to Saltford was not proceeded with. It is proposed to construct this section at the first favourable opportunity. The additions to capital expenditure account during 1907 amounted to £1,284. The falling off in the number of passengers carried has adversely affected the revenue account. The decrease in earnings may be wholly attributed to the unsatisfactory weather conditions prevailing during 1907. Various economies have been effected during the past year, and further savings in expenses are proposed which should benefit the year now current. After charging the expenses of operation and administration, there remains a balance of £13,368, to which is added balance brought forward from previous year, making a total of £13,749. Deducting interest on 4½ per cent. first mortgage debenture stock, interest on loans, and dividend on preference shares for the year to December 31st, 1907, there is a balance of £2,489, which the directors recommend should be carried forward. At the meeting on Tuesday the report and accounts were adopted.

BRISBANE ELECTRIC TRAMWAYS INVESTMENT.—The accounts for 1907 show an available balance of £54,180, including £2,267 brought forward. After payment of debenture stock interest and preference dividend there remains a sum of £17,130, out of which a dividend at the rate of 4 per cent. per annum is recommended, carrying forward £2,130. The report makes mention of the fact that the appropriation of the available balance of the Brisbane Tramways Co., of which this company holds all the shares, includes an allocation to renewals of £15,000, carrying forward £296.

BRITISH ELECTRIC TRANSFORMER.—The annual meeting was held last week, Mr. J. Albright presiding. One of the directors, Mr. A. M. Billington, dissented from certain paragraphs in the report, and an amendment to the resolution to the effect that the report be received, but not accepted, was carried. A poll is to be taken.

BROMLEY ELECTRIC LIGHT & POWER.—The report for 1907 states that satisfactory progress has been made by the company, the number of connections having increased from 71,222 to 77,802, and the revenue from £13,997 to £15,237. Considerable extensions have been made to the generating plant during the year, and an additional sub-station has been erected at Elmstead. The year's trading, including the amount brought forward, shows a profit of £12,386, and after payment of debenture interest and depreciation of stock there is a balance of £8,953. A further dividend for the last half-year, making 5½ per cent. for the year, is recommended, and the sum of £4,500 placed to reserve account, leaving £308 to be carried forward. At the annual meeting last week, when Mr. F. E. Gripper, the chairman, presided, the report and accounts were adopted. The Chairman said that if the business of the company increased during the current year at the same rate as it had during the past year or two, the directors would have no hesitation in paying a dividend of 6 per cent. The amount placed to the reserve fund was nearly 3 per cent. of the whole of their capital, and this, he thought, was a very satisfactory condition of things. No new capital had been issued during the year, but the sum of about £6,000 had been spent on machinery.

CALCUTTA TRAMWAYS.—The report for the year ending December 31st, 1907, shows gross traffic receipts £167,378, working expenses £104,235, and a revenue balance of £63,333. Against this have been debited the following amounts: Debenture interest, £15,750; interim dividend, £24,081; preference dividend, £8,253, leaving a balance of £15,248. To this is added the amount brought forward, £822, and interest earned, £2,908, making a total of £18,979, from which the directors recommend that a final dividend at the rate of 2s. 6d. per share, and that the balance of £1,778 be carried forward. In view of the heavy amount charged for maintenance during the year, the directors do not propose to make any addition to the depreciation fund, which, after adding £2,185, interest on the depreciation fund investments, and the £5,000 transferred from the balance of profit and loss account for 1906, and deducting £5,817, written off during the year for renewals, now stands at £48,080. The gross receipts are in excess of those of the previous year, which then constituted a record, by £8,521. The expenses, on the other hand, have increased by £17,317, made up of power expenses £2,024, due wholly to the fact that the plant had to be overhauled in consequence of the excessive pressure put upon it by the increased traffic, traffic expenses, £1,710, due to increased efficiency of service, maintenance and repairs, £7,164, principally due to the difficulties experienced in maintaining the cars owing to the pressure of the traffic and inadequate space for repair shops, and general expenses, £6,418, mainly due to the necessarily increased amount payable for income tax and the settlement of claims of the municipality for track rent in excess of the amount agreed for the original system. These claims had for a long time been in dispute, and a compromise was only arrived at last year. A very important factor in the reduced amount available for the service of the ordinary shares has been that so much more has been needed for the fixed charges on the new capital raised for the construction of the extensions. During the year the new ordinary shares, which had up to December 31st, 1906, been bearing interest at 5 per cent. per annum, ranked for 1907 *pari passu* with the old shares, and, in addition to this, it was found necessary to raise further capital in the shape of preference shares for the purposes of the extensions, which also became a charge upon the earnings, in priority to the ordinary capital. These additions to capital only became revenue-producing to a small extent, by reason of the unexpected delays in the construction and opening of the extensions. After their repeated disappointments, the directors hesitate to name a time for the opening of those extensions which are practically completed, but they may say that it is confidently expected by those in charge that the Howrah system, and the Behala line, will be ready for traffic by May 1st.

At the meeting on Tuesday the report and accounts were adopted.

CORK ELECTRIC TRAMWAYS & LIGHTING.—The report for the year 1907 shows receipts amounting to £51,513, and expenses, £31,797. The total balance available, after adding amount brought forward, is £20,419, from which has to be deducted interest on debentures, £4,600, leaving £15,819. The half-yearly dividends on the 5 per cent. cumulative preference shares absorbed £6,145, reserve for depreciation, £2,500, whilst the sum of £2,990 has been written off. Of the balance a 3 per cent. dividend on the ordinary shares is declared, and £733 15s. 9d. carried forward. The lighting and power business again shows very satisfactory progress, the receipts from these sources showing an increase of £2,870, or over 12 per cent. as compared with the previous year, and they now exceed the traction receipts. The large increase in the price of coal has, however, adversely affected the costs, but the directors have not raised the price of electricity as it is hoped that the high price of coal will not be permanent. Owing to bad weather experienced throughout the year and to trade depression the traffic revenue has been very disappointing, there being a decrease of £792 as compared with the previous year's receipts. During the years 1906 and 1907 it became necessary to replace certain cables laid under the bed of the river at a cost of £1,742. At December 31st, 1906, £412 was written off this amount, and the directors have now written off the balance of £1,330. During the past year a considerable length of overhead line has been renewed out of revenue, and larger percentages have been written off certain items than in former years. Capital expenditure during the year has been mainly expended on house services and additional plant for the power station. No shares or debentures have been issued during the year. The meeting is on the 28th inst.

CUBA SUBMARINE TELEGRAPH.—The report for the half-year to December 31st, 1907, shows total receipts of £17,478, and expenses £6,177. To the balance of £11,300 has to be added the sum of £6,500 brought forward from last account. £3,000 have been added to reserve fund, which now stands at £106,000, and after providing for preference dividends and 6 per cent. dividend upon the ordinary shares, a balance of £7,000 is carried forward. At the meeting on Wednesday the report and accounts were adopted.

HARROW ELECTRIC LIGHT & POWER.—Mr. G. W. Spencer Hawes presided at the annual general meeting last week, when the report and accounts were adopted. The number of units sold during the year have increased by 53,000, the largest since the company came into existence, and arrangements are in hand for the installation of additional generating plant. The total receipts amounted to £8,862, compared with £7,938 for 1906, and the total expenditure, excluding depreciation, amounted to £3,867, compared with £3,285. Fuel costs show a slight increase owing to a rise in the price of coal of 2s. 8d. per ton, whilst repairs and maintenance, in consequence of the over hauling of house meters, &c., also show an increase. After deducting debenture interest and interim dividend on preference shares there is a balance of £2,521, and the report recommends payment of a final dividend on the preference shares and 5 per cent. on the ordinary shares, leaving £479 to be carried forward. The capital expenditure during the year amounted to £1,615. The average price obtained was 5·12d. against 5·28d. during 1906, and the working expenses have increased from 2·42d. per unit to 2·45d. per unit. The sum of £1,900 has been placed to depreciation account, which now stands at £15,369. In his speech the chairman stated that, in consequence of the assessment upon the company's property having been increased from £560 to £1,200, they appealed, with the result that it had been reduced to £855.

Digitized by Google

NORTH OF SCOTLAND ELECTRIC LIGHT & POWER.—The accounts for the year 1907 show a gross profit of £1,795, including £101 brought forward from the previous year. After deducting interest on debentures and loans, and writing off £115 balance of exhibition suspense account, £467 depreciation on free wiring and meters, and putting £677 to reserve, there is a loss of £98.

OLDHAM, ASHTON & HYDE ELECTRIC TRAMWAY.—The report for the year 1907 refers first to the fact that the directors have had under consideration the question of making provision for renewals other than that ordinarily charged against the year's revenue, and the sum of £1,716 has been set aside for this purpose. The total revenue amounts to £33,296, and expenditure, including debenture interest and the amount for renewals referred to above, £26,547. Adding to the balance the sum of £494 brought forward, the sum available for distribution is £7,243. Of this, £500 is to be set aside for a cumulative sinking fund for the redemption of outstanding debentures, and an amount is placed to depreciation and reserve account, which brings this to £13,000. In addition, a 7 per cent. dividend is declared upon the ordinary shares, making 6 per cent. for the year, and £243 is carried forward. Capital expenditure during the year amounted to £898, and the total capital expenditure to date is £155,303. The company has joined the British Electric Federation.

RIVER PLATE ELECTRICITY.—The accounts for 1907, after providing for debenture interest and depreciation, show a net revenue of £17,290. The figure for last year was £12,018. Dividends of 6 per cent. on the preference and ordinary shares are recommended, and the sum of £4,000 is carried to reserve. The amount carried forward is £5,410. The dividend on the ordinary shares for 1906 was 2½ per cent.

"The Future of the Telephone Service."—Mr. Herbert Laws, in reply to Mr. A. R. Bennett's last letter on this subject, repeats the statement that he has no position in the National Telephone Co.'s organisation, and, therefore, no title. This correspondence is now closed.

North-west London Tube Railway.—In connection with the deputation from residents on the route of the Victoria-Marble Arch-Cricklewood tube railway, mentioned in our last issue, Mr. J. Devonshire, Managing Director of the Metropolitan Electric Tramways, Ltd., has written to the Chairman of the Organising Committee stating that his directors were quite disposed to think that the proposed tube railway would adequately meet all the requirements of the district. If, therefore, the tube railway is proceeded with, they will take no further steps in the direction of the re-promotion of a tramway along Edgware Road.

Middlesex County Council Tramways.—The Chancellor of the Diocese of London, Dr. Tristram, K.C., on Wednesday last week, granted an application by the Vicar and Churchwardens of St. Peter's, Cricklewood, to sell to the Middlesex County Council a strip of the churchyard for the purpose of a street widening in connection with the construction of a tramway under Section 4 of the Middlesex Light Railway Order of 1903. The agreement in question will be between the lessees of the County Council, the Metropolitan Electric Tramways, Ltd., and the purchase price, which is to be allocated to the repair of the roof of the north aisle of the church, and the decoration of the east end of the church, is £50.

Electricity in Horticulture.—The *Electrical World* describes a new application of electricity to accelerating the growth of plant which has been made by a Mr. Hartman, of Turbine, Ontario, who has employed electrical heating for garden frames for vegetables and flowers. In the comparatively cold climate of Northern Ontario a current of from 15 to 20 amperes at a potential of 110 volts has been found to be sufficient. The heater has been successfully used for two seasons, and consists of about 260 ft. of No. 12 B. & S. gage iron-wire wound in coils 2 in. in diameter. A piece of 1½-in. pipe was used in winding the coil, which was afterwards cut into seven parts and mounted on porcelain knobs on a piece of asbestos board, the coils being connected in series. The heater was placed under a rough board frame about 6 ft. by 8 ft., the floor of which above the heater was covered with about 5 in. of earth, the two sashes afterwards being used to cover the top of the frame. Electrical energy was taken from a 110-volt circuit, and, owing to the line losses, the actual current received at the frame last year was 15 amperes at 80 volts. The previous year a current of 18 amperes at 100 volts was obtained, and good results were obtained in both cases. The heat was found to be sufficient to keep the earth always noticeably warm, and in the cold early spring weather tender flowers and vegetables grew rapidly. In some cases the growth was so rapid that the plants were large enough to be set out to advantage were it not for the danger of frost.

NEW COMPANIES

MARPLES, LEACH & CO.—This company was registered on April 6th, with a capital of £20,000 in £1 shares (14,000 six per cent. cumulative preference), to adopt agreements (1) with W. M. Rolph, R. A. Marples, and S. G. Leach, and (2) with R. A. Marples and S. G. Leach, and to carry on the business of electricians, electrical, consulting, mechanical and general engineers, makers of and dealers in electric tramcars, motor-cars, flying machines, aeroplanes, carriages, cycles, and other vehicles, manufacturers of and dealers in dynamos, motors, telephones, bells, electroliers, and arc and other lamps, distributors and suppliers of electricity, &c. The subscribers are W. M. Rolph, R. A. Marples, S. G. Leach, F. K. Bull, F. Huy, F. J. Duncan, and G. A. Macdonald. No initial public issue. The number of directors is not to be less than three nor more than five; the first are W. M. Rolph, R. A. Marples, and S. G. Leach (managing directors). W. M. Rolph may, upon certain conditions, appoint other directors. Qualification (except directors appointed by W. M. Rolph), £1,000. Remuneration as fixed by the company. Registered office, 26-30 Artillery Lane, Bishopsgate Street Without, E.C.

NORTH BRITISH ELECTRIC POWER SYNDICATE.—This company was registered on March 31st, with a capital of £4,325 10s., in 4,300 "A" shares of £1 each, and 510 "B" shares of 1s. each, to promote a company or companies for constructing, establishing, and working an undertaking or undertakings for the generation, distribution, supply, and employment of electricity in the United Kingdom or elsewhere, to adopt agreements (1) with the Hon. Ferdinand C. Stanley and F. M. Voules, (2) with B. Bernheim and W. B. Cownie, and (3) with the National Electric Construction Co., Ltd. The subscribers are:—P. R. Reeves, W. J. Park, W. J. McNelly, W. Eacott, R. Bott, S. Jordan, H. O. Hill. No initial public issue. The number of directors is not to be less than three nor more than five; the first are J. T. Jervis, B. Bernheim, W. B. Cownie, and Sir Home Gordon, Bart. Qualification 100 "A" shares. Remuneration £50 each per annum (chairman £25 extra). Each share confers one vote, provided that the "A" shareholders may not vote on any resolution to reduce the capital by cancelling all the "A" shares and returning the amounts paid up thereon with such sum as shall, with the aggregate amount of dividends paid thereon, be equal to interest at 10 per cent. per annum from the date of issue. Registered office: Queen Anne's Chambers, Westminster, S.W.

PRIVATE TELEPHONE CO.—This company was registered on April 4th, with a capital of £1,000 in £1 shares, to adopt an agreement between M. Atkinson and M. C. Greenhill of the one part, and L. M. Porter of the other part, and to carry on the business indicated by the title and that of electricians, manufacturers of and dealers in electrical apparatus, mechanical and electrical engineers, &c. The subscribers are M. Atkinson, M. C. Greenhill, Florence E. Pittard, A. Green, G. S. Jacob, F. J. Radcliffe, and H. C. Bennett. No initial public issue. The number of directors is not to be less than two nor more than three; the first are M. Atkinson and M. C. Greenhill. Qualification £100.

RIPPINGILLE MANUFACTURING CO.—This company was registered on March 30th, with a capital of £2,000 in £1 shares, to take over the business of a manufacturer of electric fittings, iron, steel, and brass castings, surgical and other instruments and appliances, carried on by F. S. Rippingille in Plume Street, Aston-juxta-Birmingham, as the Rippingille Manufacturing Co., and to adopt an agreement with the said vendor. The subscribers are:—F. S. Rippingille, H. Martin, R. A. Baker, H. H. Cooper, Mrs. M. E. Jagger, W. T. Packwood, W. J. Baker. No initial public issue. The number of directors is not to be less than two nor more than five; the first are F. S. Rippingille (permanent managing director), and two others, to be appointed by him. Remuneration of managing director, £350 and 10 per cent of the net profits; of other directors, £25 per annum. Registered office: Plume Street Works, Aston-juxta-Birmingham.

"X" SYNDICATE.—This company was registered on March 31st, with a capital of £2,000 in 1,900 ordinary shares of £1 each and 2,000 deferred shares of 1s. each, to acquire and turn to account any invention relating to the production, treatment, storage, application, distribution, and use of electricity, and to carry on the business of electricians, engineers, makers, and suppliers of and directors in electricity, electric power, and light, manufacturers of electrical apparatus, &c. The subscribers are:—C. J. Feeny, V. F. Feeny, R. Fraser, F. Morse, C. H. Clarke, S. L. Morse, E. F. Cassor. No initial public issue. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first. Remuneration, £50 each per annum (chairman £100). Registered by L. B. Feeny, 19 South Molton Street, W.

Indian Telegraph Service.—According to the *Manchester Guardian*, the strike of telegraph operators is at an end, and normal working has been resumed. This must mean that the Viceroy has foregone the decision to give the new rules a month's trial.

Digitized by Google

MISCELLANEOUS CITY NOTES

CITY OF SANTOS IMPROVEMENTS CO.—Subscriptions have been invited during the week for £150,000 5 per cent (tramways) debentures at 95 per cent. These will be secured by a trust deed upon the tramways and electric lighting concessions of the company. The debentures are redeemable at par by the operation of an accumulative sinking fund of 1½ per cent. per annum, commencing in 1909. The company reserve the power to redeem all or any of the debentures at any time upon six months' notice at 105.

BABCOCK & WILCOX.—A dividend of 2s. 4 4/5d. (including bonus) has been declared, making 20 per cent. for the year 1907.

INDO-EUROPEAN TELEGRAPH CO.—A dividend for the six months ended December 31st, 1907, of 17s. 6d. per share, making 6 per cent. for the year, and a bonus of 20s. per share is recommended. The Board also recommend a special distribution of 15s. per share free of income tax, out of interest upon investments.

KALGOORLIE ELECTRIC LIGHT & POWER CO.—A dividend on the ordinary shares of 5 per cent. per annum for the six months ending June 30th, 1908, is recommended.

MARCONI'S WIRELESS TELEGRAPH CO.—It is announced that the report and balance sheet will be issued immediately after Easter. The annual meeting will be held on April 30th.

MEXICO TRAMWAYS CO.—A dividend of 4 per cent. per annum for the March quarter is recommended.

MONTE VIDEO TELEPHONE CO.—A dividend of 6 per cent. per annum less income tax is recommended on the ordinary shares for the half-year to March 31st.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—A circular has been issued to the profit-sharing secured noteholders setting forth a scheme which has been recommended by Messrs. Speyer Bros., and the London and Amsterdam Committees, for dealing with the company's 5 per cent. profit-sharing secured notes, which fall due on June 1st. The main features of the scheme are as follows :—The company will deposit and pledge an additional £3,500,000 (nominal) Tube shares, and the equity of the power house, with the London and Westminster Bank, the trustee for the noteholders, and issue £1.000,000 Prior Lien 5 per cent. bonds, due November 1st, 1920, for cash requirements, £3.000,000 4½ per cent. bonds, due January 1st,. 1933, and £5,200,000 6 per cent. income bonds, due January 1st, 1948. The noteholders are asked to exchange their notes as to 40 per cent. nominal value into 4½ per cent. bonds, and as to 70 per cent. nominal value into income bonds at par, the exchange taking place as on December 1st, 1907. In order to bind any dissentient minority of the noteholders, it is necessary to proceed with the scheme under the Joint Stock Companies Act of 1870, and for this purpose the company will be put into temporary voluntary liquidation. A receiver and manager is being applied for concurrently with the issue of the circular, so as to protect the assets during the interval caused, which must of necessity elapse before the scheme can be made binding. It is proposed that Sir George Gibb be appointed.

In the Chancery Division yesterday, Mr. H. Terrell, K.C., applied by consent for the appointment of a receiver and manager. The matter was one of great urgency, he said, because, if proceedings were taken by the holders of the profit-sharing notes against the company, the Chelsea power house might have to be shut down, and consequently the whole of the railways supplied from it would be stopped. The assets of the company, it was pointed out, consisted of very large holdings in the capital and debenture issues of the Metropolitan District Railway Co. and the three tube railways connected with it, and also large holdings in the London United Tramways, Ltd. Counsel, on behalf of Messrs. Speyer Bros. and the London and Westminster Bank assented to the application, and Mr. Justice Warrington appointed Sir George Gibb, the vice-chairman and managing director of the company.

WESTERN UNION TELEGRAPH.—A dividend of 1¼ per cent. for the March quarter has been declared. The net revenue for the quarter was $666,937.

Tramway Strike in America.—The *Standard* New York correspondent states that in Chester, Pennsylvania, the tram-drivers and conductors, with the hearty support of the townspeople, have struck to secure recognition of their trades union. The police have been fired on, and trams have been smashed.

Faraday House.—As a result of the recent scholarship examination, the Governors of Faraday House have awarded an exhibition of twenty guineas per annum, tenable for three years, to Cyril Launcelot Underwood, of the Grammar School, Bedford.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night was £59 to £59 10s. per ton (last week, £60 5s. to £60 15s.).

A NEW LAMPHOLDER.—We are asked to state that the sole selling agents for the Bruston patent lampholder and lamp cap described on page 576 of our last issue are Messrs. A. Vandam & Co., of 39 Victoria Street, S.W.

BROCKIE-PELL ARC LAMPS.—The Brockie-Pell Arc Lamp Co. have notified us that they have removed to works and offices at Wimbledon, S.W., where all their well-known makes of open type, enclosed, and flame arc lamps will in the future be manufactured under the same supervision as before. All accessories for lamps previously supplied can be obtained without any delay, and all inquiries should be addressed to the Brockie-Pell Arc Lamp Co., Wimbledon, S.W. Telephone No. : 200 National.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The Monobloc Accumulator Syndicate is being wound up voluntarily. Mr. H. Newson-Smith, 37 Walbrook, London, is liquidator.

DISSOLUTIONS OF PARTNERSHIP.—James Smith and Albert Barron, carrying on business as electric fittings merchants, &c., at 46A Holborn Viaduct, and 48–9 Farringdon Street, London, as J. J. Smith & Co., have dissolved partnership.

Mr. C. W. Stansell and Mr. R. A. Stansell, carrying on business as electrical engineers, &c., as Stansell & Son, Taunton, have dissolved partnership. Debts by C. W. Stansell, who continues.

APPOINTMENTS AND PERSONAL NOTES

Mr. Charles Lill, of East Ham, has been appointed sales engineer to the Hackney Electricity Department, at a commencing salary of £120 per annum, rising by annual increments of £10 to a maximum of £150.

Mr. Thompson, Mains Superintendent in the Erith Council's Electricity Department, has tendered his resignation.

Mr. J. Arthur Sykes, deputy engineer and manager of the Heston and Isleworth electricity undertaking, has been appointed head of the electrical department of a large rolling mill, shipbuilding and steel works in Scotland.

Councillor Barrow has been appointed Chairman of the Birmingham Tramways Committee, in place of Alderman Leale, who has been appointed Chairman of the Water Committee.

Mr. A. Harris, of the Liverpool Post Office, has been presented with a tantalus and a set of gold sleeve links and studs by the staff on the occasion of his departure from Liverpool to take up the post of general superintendent of telegraphs in Bristol.

Mr. R. Ley Alkin, A.M.I.E.E., of the electrical engineering and contracting firm of L. J. Healing & Co., of Yokohama, Kobe, and Tokyo, will shortly arrive in England on a business and pleasure trip. His address will be c/o Tozer, Kemsley & Fisher, Ltd., 84 Fenchurch Street, E.C.

NEW PUBLICATION

"Proceedings" of the American Institute of Electrical Engineers. April. (New York : The Institute.) 50 cents.

Electric Signalling for Railways.—The electro-pneumatic system of Messrs. M'Kenzie & Holland, Worcester, for operating the points and signals which has been in operation for some time at the Newcastle station of the North-Eastern Railway, is being installed at the Glasgow Central Station of the Caledonian Railway.

High-Speed Electrical Machinery.—Mr. Miles Walker has kindly pointed out a slight error in his remarks as reported on page 549 of our last issue in the discussion on Messrs. Stoney & Law's Paper. The dimensions of the 2,000 kw. rotor of which he spoke should have been given as 20 inches diameter by 40 inches long.

Telegraph Traffic.—The via Fao route has again been interrupted and restored, and there is a momentary interruption of cable communication between Mole St. Nicholas and Cape Haitien. The Japanese lines were also down until the 15th inst., resulting in the loss of telegraphic connection with Tokio and Yokohama beyond Shidzuoka. The Eastern Extension, Australasia, & China Telegraph Company have laid the cable between Cocos and Java, and the line is now open to international traffic. The rates are the same as on the "Via Madras" line. The Alaska cable has suffered an interruption beyond Sitka.

SUMMARY

An electric omnibus has made the run from London to Brighton on one charge. (Page 612.)

The following books are reviewed in this issue:—"Stationary Steam Engines," edited by William H. Fowler; "Experimental Electrical Engineering and Manual for Electrical Testing," by V. Karapetoff; "An Introduction to the Study of Electrical Engineering," by Henry H. Norris; "The Post Office Electrical Engineers' Journal"; "The Hughes and Baudot Telegraphs," by Arthur Crotch. (Page 613.)

Full statistical information regarding the working of the Liverpool Corporation Tramways is given in the annual report, which has been issued by the Traffic Manager. An analysis of the accounts shows that the total expenses per car-mile, including all capital charges, were 10·104d. A sum of £55,587 was carried to reserve, renewal, and depreciation account, and £27,793 was contributed in aid of the general rates. (Page 615.)

Some notes are given of the electrical engineering exhibits at the Birmingham Exhibition of Arts and Industries. (Page 616.)

The type of electric lift in service at Chicago in the Board of Trade Building, and known as the "Mabbs" elevator, is of interest on account of the novel construction of the mechanism. The driving motor itself is the counterweight for the car, and climbs up and down a rack in a separate shaft. The control of the motor is effected entirely through the field circuits, and special automatic braking arrangements are provided. (Page 616.)

In a Paper read before the Cleveland Institute of Engineers, Mr. H. Crowe described a form of the Ilgner system for driving reversing rolling mills, and gave an interesting series of records of current consumption in actual cases. He also dealt generally with the advantages of electric over steam driving. (Page 617.)

An interesting discussion followed the reading of Mr. Eustace Thomas's Paper on works management last week at the Manchester Local Section of the Institution of Electrical Engineers. Various opinions were expressed as to the amount of "red tape" necessary to hold the organisation together; and Dr. Garrard gave a detailed description of the cost-keeping methods in use at the works of Messrs. Ferranti, Ltd. (Page 619.)

Three wireless telegraph installations are included in the equipment of the United States Naval Academy. The main station is used for picking up and retransmitting messages from ships. Transmitting apparatus of the Slaby-Arco type is used, with a de Forest electrolytic receiver. A smaller installation on the Stone

Digitized by Google

system is used for demonstration purposes, as well as a simple form of home-made apparatus. (Page 620.)

A GOOD deal of attention is being paid in America to the electric driving of paper mills. A description of the equipment of a large mill where water power is available is given in an illustrated article. (Page 621.)

IN the course of a Paper read before the American Institute of Electrical Engineers by Mr. C. W. HINE, a number of methods of voltage regulation in rotary converters were summarised, particular attention being paid to the use of small booster machines mounted on the same shaft and connected in series with the alternating side. (Page 624.)

A LECTURE by Mr. POULSEN on wireless telephony and telegraphy is summarised, and is supplemented by notes on recent developments in the Poulsen apparatus. (Page 625.)

A PAPER, entitled "Notes on Electric Haulage of Canal Boats," by Messrs. L. B. STILLWELL and H. PUTNAM, was read last month before the American Institute of Electrical Engineers. In this Paper the authors describe some tests made on a certain canal in Pennsylvania, and a careful comparison of the energy consumption in the locomotive and mono-rail tractor systems respectively is made, the result of which is favourable to the former system. Speed limitations and locking times are among the points considered. (Page 627.)

IN a Paper before the Glasgow Local Section of the Institution of Electrical Engineers, Mr. G. STEVENSON advocated the use of squirrel-cage induction motors for electric driving in preference to slip-ring motors, even for motors up to 100 B.H.P. The author described the application of friction clutches to electric driving with squirrel-cage motors, and finally criticised the regulations of Local Authorities and supply companies with regard to the installation of squirrel-cage motors. (Page 629.)

A PAPER on the transmission of power over long distances by underground cables was read by Dr. RICHARD APT before the Elektrotechnischer Verein at Berlin recently. The author advocated the use of single-core cables in preference to three-core cables for three-phase supply at pressures above 30,000 volts, and worked through an example of transmission at 40,000 volts over a distance of 87 miles by underground cables to show that such a scheme was a reasonable proposition. A short description of the high-tension cable line of the County of Durham Power Distribution Co. was also included in the Paper. (Page 631.)

A VERY complete electric-car testing plant has been installed in an American educational laboratory. The car under test is supported on wheels representing the track mounted on shafts, which also carry flywheels for producing the equivalent of inertia of a train, and generators which can act as electric brakes to produce the effect of gradients. (Page 634.)

So far metallurgical difficulties have prevented the working up of silicate ores of nickel. But by means of a chlorination and electrolytic process it is now suggested to work the ores of New Caledonia and North Carolina. The subject of diaphragms for electrochemical processes is one of perennial interest to electrochemists, and there is still room for improvements in the various diaphragms at present employed. Under ELECTROCHEMISTRY AND ELECTROMETALLURGY some of the diaphragms at present employed are referred to. Other subjects dealt with are the production of hydrogen peroxide, the manufacture of artificial rubies, and the report of the British Aluminium Co. (Page 634.)

UNDER "Electrical Science" in the British and American Section is an abstract of a recent Paper on the effect of annealing on the magnetic properties of various magnetic substances. A Paper by BRAGG and MADSEN on the nature of Gamma-Rays and an article by HERING on the fundamental law of electromagnetic induction are also abstracted. In the Papers abstracted in the Continental Section, RIES studies the photoelectric properties of selenium, ZEEMAN observes the Zeeman effect with the interferometer, and FISCHER describes a method for exhibiting electric lines of force. Some experiments by BECQUEREL pointing to the existence of positive electrons inside atoms are also mentioned. (Page 635.)

A PATENT specification by Sir OLIVER LODGE, published last Thursday, describes an improved method of exciting a Ruhmkorff coil. Another by H. S. HATFIELD and F. M. LEWIS relates to the construction of enclosed arc lamps in which flame carbons may be used, means for circulation of the gases being provided. A specification by A. H. HUMAN describes an arrangement for electric driving with an intermittent load, with which the use of an auxiliary flywheel machine is dispensed with, and D. MARZI has one relating to an improved loud-speaking telephone apparatus, in which a lever operates the diaphragm and is controlled positively in both directions. (Page 637.)

A CORRESPONDENT sends a note with regard to the laying of underground cables. (Page 639.)

A SCHEME for a working agreement between the Belfast Corporation and the Cavehill and Whitewell Tramways Co. is now under consideration by the Corporation.—An agreement has been arrived at between the Liverpool Corporation and the National Telephone Co. by which the present charges for unlimited service shall be maintained to existing subscribers, but the message rate or the measured system of charging is to be applied to all new subscribers.—The Paddington Borough Council has rejected a recommendation by its Works Committee that a portion of the Harrow Road should be electrically lighted in preference to gas.—At meetings of the Beckenham and the Londonderry Corporations, objection was taken to sending delegates to the annual conference of the Incorporated Municipal Electrical Association, but eventually it was decided that delegates should attend.—In proposing a somewhat increased tariff for electricity supply in Brighton, Mr. J. CHRISTIE gives as his reason the high price of coal, which, he says, approximates to two-thirds of the total cost of generation. (Pages 639–641.)

THE Perth (W.A.) Postmaster-General's Department invites tenders for large supplies of telephone material.—Extensions to the Ayr Electricity Works, at a cost of £15,000, are recommended.—Two electric lifts are required by the Antwerp municipality.—Tenders are invited by the Eccles Corporation for a Lancashire boiler and 210 kw. generating set; for overhead tramway lines, with tangential suspension, telephone system, &c., by the Haslingden Corporation; for electric supplies by the Govan Corporation; for 175 double-deck roof-covered electric car bodies, with equipment for the overhead trolley, surface contact, and conduit systems by the London County Council; and for steel tramway poles, overhead line equipment, &c., by the Rawtenstall Corporation.—The Calcutta Corporation has received three tenders for public lighting, two of which are by the Calcutta Electric Supply Corporation, and the Oriental Gas Company respectively. The former has submitted alternative tenders, the annual cost of which are £43,637 and £38,818, against £34,117 by the Gas Company. The Electric Lighting Committee recommends the acceptance of the latter, but a poll of the ratepayers is to be taken. A concession has been granted by the Dutch Government to the Amsterdam & North Holland Electric Tramways Co. for the construction of a system of electric tramways in Holland. (Pages 641 and 642.)

THE report of Messrs. Babcock & Wilcox for 1907 shows a balance available for distribution of £335,664. Dividends of 3 per cent. on the preference shares, and

Digitized by Google

8 per cent. on the ordinary shares, in addition to a bonus of 4 per cent., are to be paid. The balance carried forward is £38,664, after placing £100,000 to reserve fund, and £25,000 to the dividend equalisation fund. The City of Birmingham Tramways Company's accounts for 1907 show a balance of £33,367; a 5 per cent. dividend and a bonus of 5 per cent. is recommended. The report of the Dudley & Stourbridge Electric Traction Co. shows a balance available for distribution of £11,898, and a 5 per cent. dividend is recommended. A balance of £88,523 is shown in the accounts of the British Aluminium Co. for the year 1907. A final dividend of 7 per cent. is recommended on the ordinary shares, carrying forward £36,502. (Pages 642 to 644.)

After delaying the question of improving the lighting of a portion of Harrow Road for some time, the Paddington Borough Council has refused to act upon a recommendation of its Works Committee to adopt electricity, and the present unsatisfactory condition of affairs is apparently to be allowed to continue. The cost of the present gas system is £3 per lamp per annum, or £198 for the 66 lamps in the part of the road under consideration. The Metropolitan Electric Supply Co. and the Gas, Light & Coke Co. early this year offered to improve the lighting, the former proposing to instal 24 flame arc lamps at an average annual cost of £13 each, or a total of £312 per annum, *plus* an initial cost of about £170 for new posts where tramway poles were not available. The Gas, Light & Coke Co., on the other hand, offered to instal 66 lamps, each containing two Kern burners, for £305 5s. per annum, with no initial outlay, as the new burners could be placed on the old lamp-posts. The Committee reported that they had come to the conclusion that electric lighting was undoubtedly better than gas for improving the lighting and appearance of the thoroughfare, and that the Council would be justified in adopting it, notwithstanding the slight additional cost. It may also be pointed out that a memorial in favour of electric lighting from 200 ratepayers in Harrow Road was followed by a further memorial containing 75 signatures. When the Works Committee's report was first presented to the Council early in March, it was decided—to meet the objection of the Finance Committee that the proposal would open the question of electric lighting for the whole borough, involving the Council in additional expense—to postpone the consideration of the matter until the next meeting. A special meeting was held last week, however, to consider the position, with the result above indicated. We think that the Paddington Borough Council cannot be well advised if it is so fearful of incurring unduly heavy expenses if the question of electric lighting over the whole borough is considered. Main streets can undoubtedly be better and more economically lighted by flame arc lamps than by any system of gas lighting, and although the incandescent gas lamp has hitherto been able to hold its own against the carbon filament and Nernst lamp in side streets, the advent of the metallic filament lamp has now put an entirely different complexion on the matter. In the case of a small and not over rich municipality, the burden of incurring the necessary capital expenditure for changing its street lighting from gas to electric, and the obligation of writing off that part of the capital expenditure on the former which has not yet been redeemed, may be a deterrent, but a borough so rich and important as Paddington should not evade its duty of providing its citizens with the most suitable street illumination. We quite agree with the Finance Committee that the substitution of flame arcs for gas jets in Harrow Road would probably result in an agitation by the ratepayers for better lighting in many other parts of the borough, but that is the greater reason for a beginning to be made in this direction.

The extended applications of electric driving, and the greater variety of conditions under which motors have to work, have led electrical engineers in the last few years to devote more attention to the design of motors for specific purposes. Especially in the case of large powers, a careful inspection of the nature of the work to be done, and the conditions of running, is often made before the type, or sometimes even the design, of the machine is settled upon. The user is, of course, to some extent limited in the choice of motor by the nature of the available electric power supply, and in the case of a three-phase circuit the relative claims of an induction motor with a short-circuited rotor, and one with a wound rotor and slip-rings have to be weighed. Mr. G. Stevenson, in his Paper before the Glasgow Local Section of the Institution of Electrical Engineers, considers this question at some length, and strongly favours the view that, in consequence of the simplicity of its electrical and mechanical construction, and the absence of brush-gear, the squirrel-cage motor is to be preferred to the slip-ring machine for practically all purposes where constant speed is required. He even goes so far as to say that, instead of providing some electrical method of starting up on load, the machine should be run up to speed light, and should then, by means of some suitable friction clutch, be connected to the load. There is no doubt that a well-made clutch, carefully adjusted and carefully handled, will give excellent results, especially if the motor is provided with a fairly heavy flywheel; but there is always a possibility, in the case of starting up against a heavy torque, of the clutch engaging quicker than is intended, and reducing the speed of the motor to such an extent as to blow the fuses. On the other hand, if undue slip is allowed, the wear in the clutch becomes excessive, and very frequent adjustment is required. On the whole, we are inclined to think that, in most cases, the advantage as regards behaviour in unskilled hands and cost of maintenance will lie with the purely electric method of starting. Although the slip-ring method is an extremely simple one, there are isolated cases in which trouble has been experienced, especially with motors placed in positions subjecting them to great vibration; but there are alternative methods, as, for instance, the use of the motors described by Mr. L. J. Hunt in a Paper before the Manchester Local Section of the Institution of Electrical Engineers last year (Electrical Engineering, Vol. I., pages 545 and 606). Mr. Stevenson appears to be surprised that the rules of the various supply authorities vary so much with regard to the permissible size of squirrel-cage motors which may be connected to their supply mains. It must be remembered, however, that it is only recently that improved design and construction have permitted the use of much smaller air-gaps than formerly, and have reduced magnetic leakage in the larger sizes of squirrel-cage motors, which have now a far better power factor and lower starting current.

The "solid" system of laying cables, that is to say, laying the cables in wooden, stoneware, or iron troughs, and filling up the troughs with a bituminous compound, has been for some time past the favourite method employed on distributing networks in this country. During recent years, however, there has been a revulsion in many instances in favour of laying cables, suitably armoured, "direct" in the ground. It is not only the lower cost of this method that has been the cause of its gaining favour once more, but also the fact that trouble has not infrequently been occasioned by the bituminous compound in ducts on the solid system when a heavy short-circuit occurs. Cases have been known in which melted and even burning bitumen has run down along the service cables into houses, but a more frequent cause of trouble has been the giving off of an explosive gas when some of the filling compounds are heated up to a high temperature by a short circuit. Another point is that service joints take longer to make on the solid system, and the job is more "messy" than in the case of the plain "direct in ground" system. In the course of a short note on the subject, a correspondent mentions a case, however, in which the lead covering, not protected by being laid solid, has been attacked by electrolysis, owing to insufficient bonding. He mentions, however, that the cable was laid in a clayey soil, and that clay was also used at the service boxes to keep the compound from running out. It is not sufficiently well known that certain clays have a direct chemical action on lead, and that it does not necessarily require the presence of stray tramway return currents for the lead to be attacked. Possibly in this particular case, the bonding, which should certainly not have been neglected in the first instance, may nevertheless not prove a permanent cure for the evil. While we are of opinion that the solid system is employed in a large number of instances where armoured cables laid directly in the ground would be more suitable, those who are about to adopt this latter method should first take the precaution of having samples of the soil analysed.

ARRANGEMENTS FOR THE WEEK

TO-DAY (THURSDAY), APRIL 23rd.

Institution of Electrical Engineers.

8 p.m. Extra Meeting at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, S.W., when the discussion on Messrs. Handcock & Dykes' Paper, "Electric Supply Prospects and Charges as Affected by Metallic Filament Lamps and Electric Heating," will be concluded.

TUESDAY, APRIL 28th.

Royal Institution.

3 p.m. Afternoon Lecture I. on "The Development of the Modern Steam Turbine and its Application," by G. G. Stoney.

WEDNESDAY, APRIL 29th.

Institution of Electrical Engineers: Students' Section.

7.30 p.m. Meeting at Finsbury Technical College, Leonard Street, City Road, E.C. Paper to be read: "Radio Telegraphy," by Marvin and Smith.

FRIDAY, MAY 1st.

Royal Institution.

9 p.m. Evening Discourse on "The Scientific Work of Lord Kelvin," by Prof. J. J. Larmor, F.R.S.

ELECTROBUS RUN TO BRIGHTON

One of the fourteen electric omnibuses which have been constructed by the Electric Vehicle Co. for the Brighton and Hove Omnibus Co.'s service was run on Monday from London to Brighton as a demonstration of the possibility of a run of this length (56 miles) on a single battery charge with a vehicle of the proportions of an omnibus. The omnibus ran from the Hotel Cecil to the Palace Pier, Brighton, and afterwards climbed the steep ascent from the Parade to the Western Road and proceeded to its garage in Hove without any recharging, and we are informed that another 20 miles could have been covered if necessary. The only trouble experienced was a hot bearing in one of the road wheels. No difficulty was experienced in climbing the hills encountered with the seven tons weight of the car and its load, although the speed in some cases drooped to about two or three miles per hour; but it must be understood that the omnibus was provided with the standard gear designed for an average speed on fairly level roads of 12 to 14 miles per hour. Had the gear been lower, better results could have been attained on the hills. The average current consumption on the level when travelling at 12 miles an hour was 80 to 85 amperes, and when hill climbing at five or six miles an hour, between 100 and 125 amperes, the battery voltage being 95. On several occasions the ammeter showed momentarily a consumption of 250 amperes, but by placing the motors in series the car speed was reduced and the consumption lessened to about 100 amperes. Upon completion of the run the battery showed, when discharging at 85 amperes, a voltage of 85, and on open circuit 92 volts. The lower figure shows 1·79 volts per cell, and the higher one 1·96 volts. The vehicle is of the ordinary double-decked type, to seat 34 passengers, conductor and driver, 18 outside, and 16 inside, and weighs with full complement of passengers and accumulators 7 tons. The battery consists of 47 cells with pasted plates, made by the Tudor Accumulator Co., and has a capacity of 560 ampere hours on a 5-hour discharge rate. The weight complete with electrolyte was 30 cwt. The omnibus is driven by two six-pole series-wound enclosed motors rated at 5 h.p., and running normally at 800 revs. per minute. The drive to the rear road wheels is through double reduction spur gearing and silent chains. The wheels are driven independently, so that no differential is needed. The controller is of the series-parallel drum type, operated by a handle in centre of driving seat. It provides for 5 speeds forward and 3 reverse speeds. Three mechanical brakes are fitted. The first acts on the countershaft, the second on both gear rings on the road driving wheels, while the third is an emergency electric brake sufficiently powerful to hold the car on any gradient.

Telegraph Traffic.—Nothing of importance has to be reported this week except that the dispute between the Indian Government and the telegraph operators is at an end. A five-weeks' trial of Mr. Medland's scheme has been agreed to, and absentees from duty will be permitted to return, but will lose pay for the strike period. On the 20th inst. the cable between Paramaribo (Dutch Guiana) and Cayenne (French Guiana) was restored after having been interrupted since March 14th.

Code Telegrams.—The Postmaster-General has addressed a letter to the Glasgow Chamber of Commerce in reference to the proposal at the International Telegraph Conference at Lisbon to modify the use of code telegrams. The letter refers to the tendency to compile artificial groups of words which in many cases can hardly be regarded as pronounceable, with the result that such words are difficult to transmit, and are likely to lead to error. The Postmaster-General is of the opinion that in many cases unreasonable use of the concession to use code words has been made, and he gave as an instance the following words, which appeared in a code recently submitted: buiksroty, bywrgrochx, and liqraqkper. The object the Postmaster-General has in mind, the letter continues, is that the present conditions as to the pronounceability should be somewhat more clearly defined, in order to put some limit for the future to a growing tendency which, if unchecked, cannot fail to produce results highly injurious to the telegraph service generally, and, therefore, to the public and to commerce. There is, however, no intention of adopting other than a wide and even generous interpretation which would cover the great bulk of the codes at present in use.

REVIEWS OF BOOKS

Stationary Steam Engines. Edited by William H. Fowler. 295 pp. 9¾ in. by 7 in. 326 illustrations. (Manchester: Scientific Publishing Co.) 12s. 6d.

This book is written by a well-known and experienced author, and is provided with numerous excellent illustrations. It deals with many types of reciprocating engines, and enters very thoroughly into the designs of cylinders, valves, pistons, and packings. The practical considerations of engine frameworks and moving parts are dealt with, as well as types of governors, valve gears, flywheels, and lubricating arrangements. Various representative types of slow and high-speed engines are very fully illustrated and explained. The types of slow-speed engines include those constructed by Musgrave, Van den Kerchove, Hicks-Hargreaves, the Wallsend Slipway Co., Galloways, J. & E. Wood, Escher-Wyss & Co., Allis-Chalmers, Robey, Borsig, Sulzer, Carels, Bollinckx, and Fairbairn, Combe & Barbour. These, it will be seen, include the principal makers in Europe and America, and the full descriptions, admirable blocks, and detailed drawings will be found most useful. The various valve gears adopted by the above-named makers are dealt with very fully.

The author then illustrates some well-known types of high-speed reciprocating engines. These are explained in a practical manner. Bearing pressures, cylinder clearances, &c., which require more detailed attention on the part of the designer of high-speed engines are carefully set out. Some more information might have been given on the working difficulties with piston rings, which may be said to be the only detail in high-speed engines which is not wholly satisfactory. Sectional drawings and descriptions of Willans & Robinson's central valve, Belliss & Morcom, Browett-Lindley, W. H. Allen, Brotherhood, Scott, Reavell, McLaren, Peache, Sissons, Clarke-Chapman, Westinghouse, and Alley & McLellan's engines are given, so that almost every well-known type of British high-speed engine is described.

In the chapter on governors, reference is made to a Paper by Captain Sankey on the subject of the relative advantages of throttle and cut-off governing. Strange to say, no reference is made to the late Mr. Willans' paper, read in 1893, as we might have expected. The principal types of governors in use are fully dealt with. The kinematics and construction of engine flywheels form a very excellent chapter; we do not, however, see any reference to the trouble due to slackening of keys, which has proved a serious difficulty in some large flywheels. The concluding chapter on condensers contains a lengthy reference to Professor Weightman's Paper, read before the Institute of Naval Architects. Jet, surface, barometric jet, ejector, and evaporative condensers are shortly described.

We think the author dismisses the subject of cooling towers too shortly, as only steel towers are described, and no reference is made to the more commonly used wooden towers. We would suggest that the author might with advantage also include in a future edition the recommendations of the Engineering Standards Committee as a reference, and as well as a chapter on pipework. We strongly recommend the book to all engineering students, draughtsmen, and engine designers.

Experimental Electrical Engineering and Manual for Electrical Testing. By V. Karapetoff. 790 pp. 9 in. by 5¼ in. 538 illustrations. (London: Chapman and Hall.) 25s.

This book, says the preface, is written as a laboratory manual suitable for the general electrical engineering work of most American colleges of engineering. It will, however, not only be read with interest by those engaged in teaching in this country, but will also be found useful to many engaged in actual work.

It is arranged on what the author calls the "concentric" system, for fuller details of which he refers us to his paper at the 1907 Convention of the A.I.E.E. While each subject is dealt with by itself, it is intended that the book shall be gone through three times; first taking the elementary part of each chapter, then a second time going further into each subject, and the third time taking the more advanced parts. The method appeals to us. By having the whole in one text-book, the second and third course men are made sure of their back-work, while the first course man, if he is worth anything, will skim over the more advanced parts, and will see what his work is leading to—an encouragement the first course man frequently lacks.

One of the most valuable parts of the method is the "report" which the student is constantly being called on to make, on all kinds of apparatus and plant, from ammeters and bridges to lifts, wiring, and tram-car controllers. Reasonable lines for these are pointed out, but so as to encourage individuality, not uniformity. Most English teachers will envy the wide range of plant on which his American colleague appears to be able to turn his pupils loose.

In the earlier part of the book—Instruments, the Magnetic Circuit, Lighting, &c.—there are a few points which might be corrected. Photometry is well treated, and there is an excellent chapter on illumination; but we cannot understand the Marshal luminometer being accepted without comment. It was brought out and abandoned by Mr. (now Sir William) Preece in very early days, and the method of varying the power of the standard lamp by voltage is very little better now than then. Among meters, again, the way in which "originality" is allowed to the Sangamo Meter makes one think the author has never heard that the Ferranti has been in wide commercial use for years. There is a little mistake of a decimal also in the Carey-Foster Bridge. Its limit of accurate work is given at 0·01 per cent., whereas it is nearer to one in a million in everyday work.

A very wide range is dealt with in lines, generators, motors, efficiency tests, transformers, armature winding, switchboards, railways, controllers, &c. To deal thoroughly with any one of these subjects would take up the whole book; to deal superficially with all would be useless. The author steers the middle course with some skill, giving a sufficient number of well-chosen groundwork matters, clearly dealt with and worked out, and a few practical commercial examples. He doubtless feels that a student who has gone steadily through what he finds in this book will have learnt to work, and be able easily to read up any branch in which he wants to specialise, besides having a fairly wide knowledge on most work outside his own branch.

As to mathematics, the author's feeling seems to be that for engineers, graphics are better than analytics, and neither than either. We think that in this many engineers will agree with him.

There is one unpleasing little bit. Joint resistances are treated as a mid-Victorian Cambridge don would have done it, instead of by a few lines of common sense and reciprocals; and then left in the form $\frac{1}{R_{jt}} = \Sigma_1^n \frac{1}{R}$, from which the pupil may—or may not—disinter the only formula that he will ever want, viz., $R_{jt} = R_1 R_2 / R_1 + R_2$. But perhaps this is only put in to show how bad men would have written this book, just as the four appallingly bad illustrations serve as a foil to the remaining 534 which are exceptionally good.

An Introduction to the Study of Electrical Engineering. By Henry H. Norris. 404 pp. 9 in. by 5¼ in. 179 illustrations. (London: Chapman and Hall.) 10s. 6d.

The idea of this book is good—to give a general view of electrical engineering based on the various applications familiar to all; a general view, not exactly to the man in the street, but rather to the technical man in other branches. The further the writer goes the further he gets away from this idea, which is a pity. When he remembers for whom he is writing he sometimes does put things so very nicely and clearly that we hope for a second edition, leaving out half or three-quarters of the present matter, and replacing it with as good as that which remains.

The first fifty pages may be summed up as "who first did what, and when," and they form a very convenient, short, historical summary. The chapter on electrical quantities and units is very clearly put, but is more suitable for clearing the brain—and it often wants it badly—of the working engineer, who knows them already in practice, rather than for the beginner. One excellent point, here and in other parts, is that immediately after a statement, one or more numerical examples are often given: merely question and answer, which can be worked out from what has just been said. This clinches the matter on the spot, and makes sure it is really understood. We generally find such examples, if given at all, are collected at the end of the chapter, where they are but little use, as most readers cut them. Another excellent feature is giving at the beginning of the book a list of "Symbols used in Electrical Literature." It saves a good deal of trouble. Doubtless the omission of some such words as "by me and my friends" is a printer's error.

As to the rest of the book, if rewritten with Figs. 75–6, 82, and 133–4 as patterns of what is wanted, and with some slight sense of order, proportion, and sequence, the whole would make a very good and useful work, for there is much good matter in it.

This present edition, indeed, may be of service to a man who has been at work for some years, and lacks a clear conception on certain points.

The Post Office Electrical Engineers' Journal. Vol. I. Part I. 80 pp., 9¾ in. by 6 in. Published for the Institution of Post Office Electrical Engineers, by H. Alabaster, Gatehouse & Co. Price 1s. nett quarterly.

The new quarterly journal of the Institution of Post Office Electrical Engineers differs from the majority of the official journals of scientific and engineering institutions. It does not contain, as might be expected, duly revised and corrected versions of Papers read before the Institution, with reports of the discussions, but is made up of a number of articles which have apparently been contributed specially to the Journal. Only three pages are devoted to minutes and reports from the nine local centres of the Institution. The journal starts with some "words of welcome" by Sir John Gavey, and it also contains a short statistical article on telephone progress in London by Mr. G. F. Preston (General Manager of the Post Office London Telephone Service). There are several excellently written technical articles, some of which, however, suffer considerably by the very poor reproduction of the diagrams with which they are illustrated.

Messrs. C. C. Vyle and E. V. Smart describe the polarised sounder designed by Mr. Vyle, in which the cores of a sounder, resembling in general appearance the ordinary pony pattern, are inductively magnetised by a permanent magnet placed with its poles at a distance of five mils below the bottom of the cores. This keeps the magnetisation on the steep part of the curve, without, however, there being any danger of reversal. It is stated that a 500+500-ohm polarised sounder of this pattern can be actuated by half a milliampere, that three milliamperes can produce Morse characters at 20 words per minute, and 10 milliamperes give strong loud-working signals. The inductance of the instrument is 62 henries. At present the sounder is in use on a 400-mile line from London to Glasgow, and on other long-distance lines. Mr. Chas. E. Hay has contributed an article on the "Common Battery Duplex," a system in which a line is worked duplex from a battery placed at one end only; he has devised a means of overcoming previous difficulties in working this system. A serial article on "The Telephoning of London," is commenced by Mr. W. Noble, Superintending Engineer of the Metropolitan Central District. The first instalment deals with the initial survey of the underground duct construction. Among the interesting figures given in Mr. Preston's statistical article already alluded to are the average number of calls per line per day in various London exchanges. At the Central Exchange the average is the highest, but yet only 6·81, while at Hampstead it falls to 3·1. These low figures, however, are obviously due to the large proportion of message-rate circuits; there are 30,245 subscribers on the message rate as against 3,855 on the unlimited service rate Other articles are "The Typewriter and Piece Work in Telegraphy," by Donald Murray (on the large use of the typewriter and of abbreviations on the United States telegraph system), "Common Battery Telephone Transmission Systems, and Some Methods of their Application by the Post Office," by M. Ramsay; "Glasgow Trunk Exchange—New Equipment," by J. S. B.; "The Zones and the Trunk Lines," by John Lee (Assistant Traffic Manager), "The Skerries Wireless Telephone," by J. S. Elston (an earth-plate conduction system put down in 1899 or 1900, and apparently not giving very good results).

The journal is edited by Messrs. H. R. Kempe, H. Hartnell, A. W. Martin, J. E. Taylor, T. F. Purves, A. O. Gibbon, and D. H. Kennedy (Managing Editor). We are surprised to see that a journal edited by engineers of the Post Office Telegraph Service, and circulating practically only among this class of readers, should be permitted to publish advertisements of electrical manufacturing firms.

The Hughes and Baudot Telegraphs. By Arthur Crotch. 83 pp. 4¾ in. by 7 in. 41 illustrations. (London: S. Rentell & Co.) 1s. 6d.

This little book is almost entirely descriptive of the instruments named in the title, and takes it for granted that the reader is acquainted with the general principles of telegraphy. The Hughes type-printer has never been extensively used in this country, and thirty years ago had nearly disappeared from the Post Office stations. For international lines the advantage of delivering the actual instrument slip in plain letters, and so avoiding errors due to linguistic differences, has served to keep it in general Continental use, in spite of the somewhat highly skilled labour needed for the operation and maintenance of a complex instrument. So when the Post Office took over the cables of the Submarine Telegraph Company, the Hughes was again numbered among Post Office apparatus. To those familiar with the original instrument, the description in the book under review will be of interest, as showing how it has been improved in certain details, of which the substitution of an electric motor for the heavy driving weight must be an immense relief to the operator. The governor described is another considerable improvement.

In the diagram of the Hughes Duplex Repeater, Fig. 16, it is impossible to follow the action of the two six-way switches and the "Simplex-Duplex" switch, and the text gives no assistance. Neither is the function of the Wheatstone receiver in the "leak" circuit mentioned, nor the speaking sounders shown. This may lead to no difficulties to those in the "Service" who recognise the repeater set as available for either Morse or Hughes working, but is perplexing to the less well informed. The diagram is extremely difficult to follow at all, owing to the confusing effect of crowded parallel lines, and the absence of identifying numbers or letters at the terminals.

The description of the Baudot system is not easy to read, but with a little care, and reference backwards and forwards, a clear understanding of the system, and the somewhat intricate apparatus employed, is attainable, and understanding will result in admiration for the ingenuity displayed throughout. The reference backwards and forwards is partly due to several cases of wide divorce between the figures and the text describing them; an irritating characteristic of many descriptive works, which the author and printer would do well to alleviate in future editions in this case. The author's plan of starting by a detailed description of the mechanism, and finishing with a statement of what it does, might also be modified or reversed with advantage. It gives one the feeling of marching with a guide who points out a series of landmarks with no indication of what they lead up to. Nevertheless, the careful reader will reach the destination of comprehension, and perhaps that is in itself sufficient praise for such a highly technical descriptive work. The diagrams are for the most part clear and intelligible. Fig. 37 requires lettering to distinguish the "correcting" and "corrected" stations. The half-tone blocks of the Hughes instrument and repeater should be replaced by better specimens.

LIVERPOOL CORPORATION TRAMWAYS ACCOUNTS

THE seventh annual report of the Traffic Manager of the Liverpool Corporation Tramways for the year ended December 31st, 1907, has just been issued. An analysis of last year's report was given in ELECTRICAL ENGINEERING, Vol. I., p. 585. There has been no extension of track during the year, the length of track operated remaining at 104 miles. A few new routes have been arranged, and two extensions are proposed. Full particulars of the routes, services, and fares, together with a map of the system, are given. During the year there were 37 fatal accidents caused by vehicles in the city, of which 10 were tramway accidents. The plough lifeguard with which the cars are fitted has pushed 27 people who had fallen in front of the cars, or had been knocked down, clear of the metals without any serious injuries. The ratio of fatalities to passengers carried amounted to 1 in 12,404,324, as against 1 in 30,523,632 in 1906. The total number of cars in stock at the end of 1907 was 515, of which 402 were double-deck cars with top canopies, and 86 were double-deck cars without top canopies, the remaining 27 being single-deck cars. On an ordinary day 398 cars are in service. The improved sanding apparatus, described in full in ELECTRICAL ENGINEERING, Vol. I., p. 585, and which was designed by Mr. C. W. Mallins, the Traffic Manager, has proved so satisfactory that it is to be fitted to all the cars. The following figures for the last three years show the increase in traffic on the system, which comprises 104 miles of track:—

	1905.	1906.	1907.
Passengers carried ...	119,123,644	122,094,528	124,043,239
Car mileage	12,067,033	12,115,934	12,231,799
Traffic receipts ...	£550,084	£563,777	£572,822

Thus the increase in the number of passengers carried for the year 1907 over 1906 was 1,948,711, or 1·59 per cent. The increase in receipts was 1·6 per cent., and the increase in mileage 0·95 per cent. The average earnings per car-mile for 1907 amounted to 11·24d., as against 11·17d. for 1906, or an increase of 0·07d. per car-mile. The density of the traffic is still increasing. In the busy season of 1906, 5,967 cars arrived at and left the Pierhead on the different routes per day. The figure in 1907 was 6,075 cars per day, and the number of cars passing the Town Hall was 3,712 per day.

The table in the opposite column is an analysis of the cost of working entirely under electric traction for the years 1906 and 1907, reduced to pence per car-mile.

The working expenses analysed in this table amounted to £398,734, and the receipts from all sources were £598,366, of which £572,822 was traffic receipts as given above, and £7,389 was by advertising. Of the balance of £199,632, interest and sinking fund absorbed £110,361, and £5,891 was paid as rental of leased lines, leaving a final excess of income over expenditure of £83,380. Of this £27,793 was contributed towards the rates, and £55,587 was carried to reserve, renewal, and depreciation account.

The average length of a penny stage was the same as for the previous year, namely, 2 miles 699 yards, and the average fare per passenger was also the same, or 1·108d.

The total capital expenditure up to December 31st, 1907, including the purchase price of the horse undertaking amounted to £1,913,189, of which £11,378 was spent during the year under review. Of this sum of £11,378, over £10,000 represents the cost of new cars and their electrical equipment. A table, showing how the capital expenditure up to December 31st, 1906, was made up, was given in the article to which reference has already been made.

ANALYSIS OF EXPENSES PER CAR MILE

	Year ended Dec. 31st, 1906.	Year ended Dec. 31st, 1907.
Traffic expenses—	d.	d.
Superintendence	·090	·098
Wages of motormen and conductors ...	1·938	1·973
Wages of other traffic employees ...	·322	·322
Cleaning and oiling cars	·261	·265
Cleaning, salting, and sanding track ...	·033	·035
Fuel, light, and water for car depots, cash offices, and waiting rooms, including cleaning	·041	·041
Ticket check, including wages of inspectors and clerks	·126	·135
Uniforms, badges, bags, and belts ...	·078	·058
Lighting routes	·003	·003
Miscellaneous	·053	·050
	2·945	2·980
General repairs and maintenance—		
Permanent way	·636	·624
Electrical equipment of line	·123	·152
Buildings and fixtures	·050	·031
Workshop tools and sundry plant ...	·013	·011
Cars	·807	·825
Other rolling stock	·002	—
Miscellaneous equipment	—	·001
	1·631	1·644
Power expenses—Cost of current... ...	1·980	2·109
General expenses—including rates and taxes, management charges, compensation and law charges, &c. ...	1·079	1·090
Total working expenses (not including capital charges) ...	**7·635**	**7·823**
Rent of leased lines	·116	·116
Interest and sinking fund	2·171	2·165
Total expenses (including capital charges)	**9·922**	**10·104**
CAR MILE EARNINGS	11·17	11·24

Wireless Telegraphy.—It is reported that the Canadian Government proposes to establish a wireless or cable telegraph service between Prince Rupert and Queen Charlotte Islands and between various larger islands.

Electricity in Brazil.—In a report upon the mining industry in the State of Minas Geraes, Brazil, by Mr. G. Campbell, H.M. Vice-Consul at Rio de Janeiro, the following paragraph appears under the heading "Electricity": "Fortunately, there are abundant supplies of water, which are being used for working the mines and for lighting towns. There is a great future for electricity in the country, and it is already developed to a considerable extent. Small towns of 4,000 inhabitants have electric light, and some have trams. It is true that at present it is impossible to read a book by the light, but that will be improved. Add to this that there are numbers of small factories whose existence must depend on economy, that butter and cheese are made in large quantities, and that Brazil is ambitious to become a manufacturing country, and there should be many opportunities for electrical engineers." The report later states that a firm of electricians might be able to obtain some small orders, and could use this opportunity to study the country and the abundant water supply with a view to eventually installing a plant for smelting purposes.

The Iron and Steel Institute.—The annual meeting of the Iron and Steel Institute will be held on Thursday and Friday, May 14th and 15th, at the Institution of Civil Engineers, and its annual dinner will be held on the first of these days. Accompanying the programme of the meeting is a description of the new premises into which the Institute are moving, consisting of a suite of 10 rooms, formerly occupied by Sir Douglas Fox & Partners at No. 28 Victoria Street. Although in the same building as the Institute's former quarters, the accommodation afforded is much increased. Amongst the Papers which are expected to be discussed is one on an experimental electric furnace for the smelting of iron, by Prof. B. Igewsky (Kiev), and a Paper by Mr J. W. Lambert on the pyrometric installation of the Ordnance Factories, Woolwich. It is announced that the autumn meeting of the Institute will be held at Middlesbrough, and that an invitation to members to accompany an excursion of the Canadian Mining Institute in September has been received. It is proposed to visit the mineral areas of Eastern Canada, including the silver-cobalt ore region, the nickel and iron mines of Ontario, the asbestos and chromite regions of Quebec and other districts.

BIRMINGHAM EXHIBITION OF ARTS AND INDUSTRIES

We announced in our issue of March 26th the opening of an Exhibition of Arts and Industries by the Lord Mayor of Birmingham in the Bingley Hall, the proceeds of which are to be devoted to the building of a convalescent home under the auspices of the Hospital Saturday fund. As is usual in exhibitions of this nature, there is a considerable section entirely devoted to engineering.

The first exhibit to attract our attention was a 60-B.H.P. suction gas plant made by T. H. & J. Daniels, Ltd., Stroud, Glos., which generates gas for driving an adjacent 63-B.H.P. vertical high-speed gas engine by Messrs. E. S. Hindley & Sons, Bourton, Dorset. The engine is coupled direct by a solid bolted coupling to a direct-current generator mounted on an extension bed-plate, the speed of the combined set being 500 revolutions per minute. Forced lubrication is used; the engine has three cylinders, and magneto ignition gear is employed, the timing of the spark being adjustable whilst the engine is running, either on the three cylinders simultaneously, or on each cylinder separately. The governing is effected by throttling the gas supply, and consequently each cylinder makes an explosion in every cycle. The Daniel gas plant above mentioned also supplies gas for a 12-B.H.P. "Dudbridge" gas engine, the plant being capable of running this small engine on light load alone, thus proving that suction plants can work at loads far below their normal rated capacity, a fact which the performances of many plants have gone to deny.

The 60-h.p. producer and engine are daily supplying current for the exhibition at a cost, we were informed, of 1/10d. per B.H.P., including water and anthracite coal at 33s. 6d. per ton. The National Gas Engine Co. are exhibiting three of their engines; one of these, of 6·5 B.H.P., is supplied with gas from a suction producer of their own design, and provides light for company's stand at a cost stated by the makers to be 1/5d. per B.O.T. unit. This engine is of the horizontal type, with massive flywheel, and the dynamo, which is direct-coupled to the engine crankshaft, is carried on an extension bed-plate.

Several motors, switchboards, and measuring instruments of various types are shown by the Walsall Electrical Co., Ltd., who are the official electrical engineers and contractors to the exhibition. Messrs. Mawdsleys, Ltd., of Dursley, Glos., are showing a number of their motors, dynamos, and electrically-driven machines; it is one of the dynamos made by this firm which is driven by the Hindley gas engine above mentioned. Several machines for the removal of iron from brass and other metal are exhibited by Messrs. The Rapid Magnetting Machine Co., Ltd., of the Crescent, Birmingham. One useful machine on view was for the removal of iron from destructor furnace slag and other heavy material. Their standard type of machine separates iron from brass and other metal turnings. The only representatives of the makers of electrical fittings are Messrs. Best & Lloyd, of Handsworth, Birmingham, who display a number of pendants and wall-brackets in a variety of styles and finishes, prominent among these being the well-known "Surprise" pendant.

The University of Birmingham have a stand at which are to be seen the Hoho welding process, bridge megger, arc and mercury vapour lamps, and samples of insulators and accumulator plates. A choking coil, recently built at the University for experimental investigations, was also a feature of this stand. The City of Birmingham Electric Supply Department occupy a very prominent position and attract a large amount of attention. The exhibit is intended to interest prospective consumers, and a feature of the stand is the inquiry office, at which, according to the placards, information and advice can be obtained in connection with any application of electricity. There is a display of metallic filament lamps (Osram and tantalum), the efficiency of which is demonstrated by measuring instruments, and a number of flame arc lamps are also to be seen. Various motors, some driving machines and tools, are shown in operation. Heating devices of both the convector and radiator types are largely in evidence, and there are also some electric ovens and other cooking apparatus.

Accounts of the North Metropolitan Electric Power Supply Co.—A slight error occurred in the arrangement of the figures of the analysis of the revenue account of this company on p. 586 of our last issue. The figures 0·066 pence per unit and the corresponding total £3,075 should stand for the total distributing costs, and the total works costs should be £29,678, or 0·637 pence per unit. The error does not affect the final total of £40,252, or 0·865 pence per unit.

American Protest Against the Revocation Clause in the New British Patents Act.—It appears that considerable exception has been taken in the United States against the clause in the new Patents Act under which any person may apply for revocation of a patent on the ground that the manufacturer of the patented article is carried on exclusively or mainly outside the United Kingdom. No similar clause exists in the United States, although in some European countries a similar protective condition is in force. It is reported, however, that negotiations are on foot for "a conventional arrangement" between the Governments of Great Britain and the United States, "by which the lapse of a patent for non-working may be reciprocally waived."

AN AMERICAN DESIGN OF ELECTRIC LIFT

In a recent issue of the *Western Electrician* (Chicago), a description is given of the electric elevators installed in the Board of Trade Building in that city. The requirements of the service in this building are very severe, in that the traffic is not only heavy throughout business hours, but exceptionally so while the Exchange is in session, for large numbers of brokers have to be carried with the utmost speed from the Exchange floor to their respective offices. When the building was constructed in 1883, four hydraulic elevators, operating at a speed of 500 ft. per minute, were installed. These machines were replaced in 1887 by electric elevators of the screw type, and an additional electric elevator of the drum type was installed to run from the main to the Exchange floor only. A fifth electric elevator of the Mabbs type was installed in 1902, and in 1906 the older screw-type elevators were also replaced by elevators of the Mabbs type.

The principle of the Mabbs elevator is that the operating motor constitutes the counter-balance of the car, and works up and down a rack. The cable and sheave rigging is arranged so that the motor is geared two to one; *i.e.*, when the driving motor runs up half the height of the building, the car is lowered from top to bottom, and *vice versa*. The cables attached to the car run over a sheave in the space over the elevator-shaft, then down again and around a sheave at the top of an A-frame fixed to the driving motor, and are fastened to a girder about midway of the height of the building. The driving motor has a vertical shaft, and drives two worm wheels on horizontal shafts on either side of the motor. On each end of each of these shafts is a pinion. These engage the four racks mounted on the faces of the vertical cast-iron columns at each corner of the motor-shafts. Thus, when power is supplied to the motor, it climbs up or down the motor shaft, moving the car respectively down or up the elevator-shaft. The two shafts need not be close together; in this particular installation the two shafts are separated by 35 ft. in one instance. The conductors supplying the current to the motor are arranged on porcelain blocks mounted on the inner face of one of the cast-iron columns. The contact-brushes, of which there are eight per motor, have each a contact surface of over one square inch, and are mounted on self-adjusting holders.

The motor is entirely controlled through the field circuits. The field system consists of four poles on which are three distinct windings, a light series field winding, used only in starting, the main shunt field winding, which is always connected while the motor is running, and an auxiliary shunt winding which is gradually cut out during accelerating. With the main shunt field winding alone excited, the maximum speed of the armature is obtained, which is somewhat over 1,000 revs. per min. The motor is enclosed, and the gearing below is entirely enclosed in a case, which is filled with oil to nearly the centre of the horizontal shafts. The oil does not have to be replaced more often than once in every two and a half years. The pinions and racks, which are lubricated with grease, make less noise in operation than the motor. All the gearing is machine cut, and is of steel, with the exception of the worm wheels, which have phosphor-bronze rims. The wear on the rims has been insignificant.

Below the sheave mounted over the motor is a slack-cable device which trips the main circuit-breaker immediately any cable is loosened. Below this device and on top of the vertical shaft of the motor is the automatic friction brake, which consists of a pulley and brake-shoes applied by the action of a spring. When the machine is running, these shoes are held out of contact with the brake pulley by solenoids; consequently, directly the current is cut off by the operator or by the action of the circuit-breaker, this friction brake is automatically applied.

At the top and bottom of the elevator-shaft are placed powerful pneumatic buffers. The control of the elevator motor is effected entirely by electromagnetic switches, which are interconnected to give a definite sequence of action with rapid and smooth acceleration and retardation of the car. Speed control is through adjustment of the auxiliary shunt field. In stopping the machine, current is cut off from the armature, and the latter is short-circuited through a bank of resistances, thus obtaining a considerable braking effect.

Automatic stops are placed at the upper and lower limits of travel of the machine, which slow down the motor and cut off the current in case of negligence of the operator. The worm gearing is a preventive against the car starting to move without the application of motive power. The cars are six square feet inside, and the height of travel is about 130 ft. The motors have an average energy consumption of 3·5 kw. hours per car-mile. The running speed is about 550 to 600 ft. per minute.

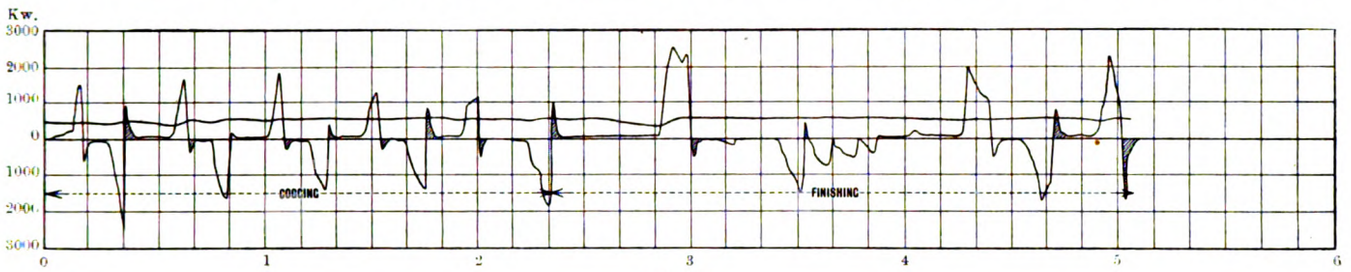
ELECTRICALLY-DRIVEN REVERSING ROLLING MILLS

MR. HENRY CROWE read a Paper on April 6th before the Cleveland Institute of Engineers on the above subject. He said that in these days of keen competition possibilities of any reduction in the cost of the manufacture of iron and steel were of great importance. He did not propose to describe electrically-driven three high or other continuous-running mills, but remarked that when a works possess their own power station, or can purchase electricity cheaply enough, there could be no doubt of the many advantages of this system.

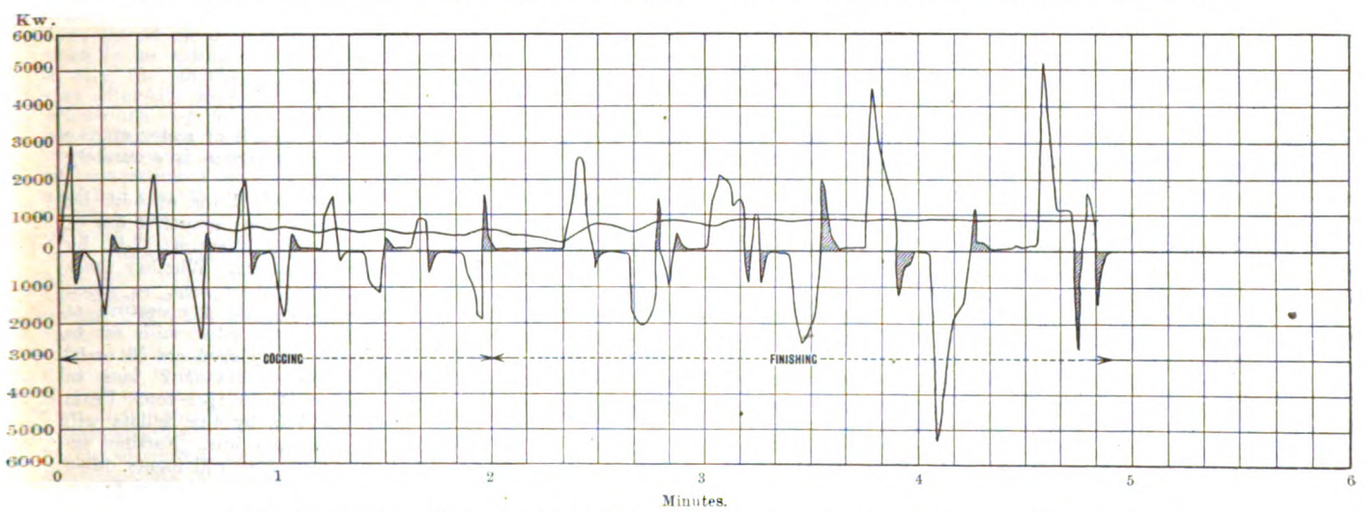
He then showed a diagram of the main electrical connections of a reversing mill equipment of the well-known Ilgner system. The current from the power station passes an isolating switch and a three-pole oil switch fitted with an overload release, and the amount of current and its potential is recorded by the usual ampere, volt, watt, and watt-hour meters. The current then passes through a transformer, which operates the slip resistance motor, and on to the induction motor, direct coupled to the continuous-current generator and the flywheel of the Ilgner set.



The brushes of the reversing mill motor are directly coupled to the brushes of the generator of the Ilgner converter set. The armatures of the generator and the mill motor are protected against excessive currents by the automatic circuit breaker, and these machines are further protected by a no-voltage release in connection with the fields of the mill motor.

The current required for exciting the field magnets of the mill generator and the reversing mill motor is obtained from a special motor-driven exciter set.

In starting up, the Ilgner converter set and the exciter set are run up to speed. The field magnets of the mill motor are generally fully excited, and the polarity of these magnets is never changed; but this is not so with respect to the magnets of the generator. When the controlling lever is in mid-position there is no current passing round the field magnets of the generator, consequently no current generated and therefore the mill motor is stationary. On moving the controlling lever in one direction the fields are excited and the mill turns at a speed and in the direction of rotation corresponding to the position of the controlling lever which regulates the amount of current passing round the fields and the direction of that current. It is convenient to be able to run the mill at a greater number of revolutions than that corresponding to the maximum torque, and this is effected by the operator pulling the controlling lever still further over, which puts a resistance in series with the mill motor fields, reducing the density of the fields and so increasing the speed of the mill with a corresponding decrease in torque.



In large rolling mills the power required may vary from 0 to 10 or even 15,000 h.p. in either direction, but these great powers are not required for long periods, and to attempt to drive a mill of such powers without the aid of some system which would average up the power would be practically impossible, such great fluctuating loads would have disturbing effects on any power station, and the cost of the power station would be prohibitive had it to be made large enough to provide for the heaviest loads. By the use of heavy fly-wheels running at high speeds a great amount of energy can be stored up and readily given out again.

The method of slowing down the speed of the fly-wheel can be done in direct-current motors by suitably compounding the fields, and in an induction motor by inserting resistance in the rotor winding by what is known as the automatic.

Elongation 14·6 times. Average power put into rolls, 338 kw. for 310 seconds. Power put into converter 488 kw. or 48 units=29 units per ton rolled. Efficiency 69 per cent.

FIG. 1.—POWER CURVES FOR $15\frac{3}{4}'' \times 15\frac{3}{4}''$ INGOT. 1·45 TONS ROLLED IN 15 PASSES INTO 4″ × 4″ BILLETS.

Elongation 63 times. Total units put into mill, 44·96. Total units put into converter, 60·8. =45 units per ton.

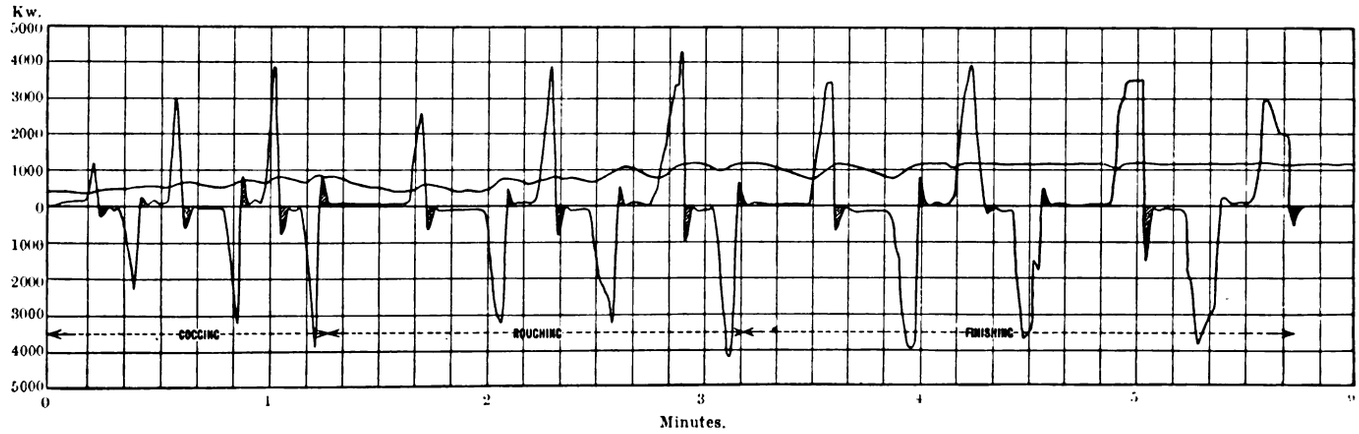
FIG. 2.—POWER CURVES FOR $15\frac{3}{4}'' \times 15\frac{3}{4}''$ 1·35-TON INGOT ROLLED IN 17 PASSES INTO 2″ × 2″ BILLETS.

In one form of this, the resistance consists of metal plates suspended in earthenware tanks containing water; the position of these plates, which is controlled by the "slip motor," regulates the amount of the resistance. Should the current from the mains increase, the current to the slip motor, which is supplied from a series transformer, also increases, with the result that the resistance plates are lifted, thereby adding resistance to the rotor of the induction motor driving the converter set, and thus reducing the speed of the motor and allowing the fly-wheel to give up the requisite amount of energy to pull the piece through the rolls. On the load decreasing, the current to

Digitized by Google

the slip regulating motor also decreases, its torque therefore diminishes and the resistance plates fall, reducing the resistance in the rotor of the induction motor, which therefore increases its speed, and the energy which was taken out of the fly-wheel is now restored. This slip-regulating resistance is also used as a starter for starting up the Ilgner converter set. After the stator switch has been thrown in, the resistance of the rotor is gradually cut out by the lowering of the resistance plates by means of a hand-wheel. The liquid forming the resistance is kept cool by means of a series of cooling pipes placed in the tank, through which a continuous stream of cold water is circulated.

Special precautions have to be taken to make the generator and the mill motor run sparklessly with the brushes in one fixed position. In addition to the ordinary exciter, the installation at Teschen is provided with a second exciter generator, whose field current is that of the main current driving the mill motor; its voltage therefore corresponds to the load on the mill. The current generated by this special exciter supplies special windings on the mill motor and generator. The mill motor fields are further strengthened, this device has the effect of preventing excessive rushes of current, and prevents the circuit breaker from flying out should there be any careless handling of the controller.



It might be supposed that the power required to make the mill motor and rolls reverse rapidly and frequently is a very considerable loss, but in this system of control the power given out by the coming to rest of the mill motor and rolls can be given back to the fly-wheel. The control lever is moved in such a position that the back electro-motive force in the mill motor is greater than that of the generator of the converter set. The mill motor thus becomes a generator and the converter generator a motor, so that the mill receives a heavy braking current and at the same time the power used in stopping the mill is not wasted, but is partly restored to the fly-wheel set.

The author then referred at some length to the advantages of steam engines possessed by the electric motor for rolling mill work in the way of uniformity of torque.

An important advantage of the even torque of the electric drive is that there is less likelihood of breakage of boxes, spindles, and wobblers of rolls. Yet another advantage is the fact that when the piece bites the rolls the mill does not appreciably slow down, as instantly the mill motor tends to slow down extra current flows through the armature owing to the reduced back electromotive force, so that the mill motor exerts automatically the requisite torque to pull the piece through the rolls. Therefore the mill will not stall, but will pull anything through up to the maximum power for which the circuit breakers are adjusted. For the same reason the mill will not appreciably race when the piece is through the rolls, although the driver will naturally use the inertia of the mill to perform the rolling of the tail end of the bar, and for this reason electrically-driven mills run exceedingly smoothly and quietly. With regard to the question of acceleration, there is no doubt that the steam engine with the small inertia of its moving parts can reverse and accelerate much more rapidly than any large reversing mill motor that has yet been put to work. But this is a question of putting plenty of power into the motor and of keeping the diameter and weight of the armature down. At the same time it is not always wise to reverse a mill too quickly; for example, when there are three or four stands of rolls coupled together, to reverse such a mill too quickly is not wise, as it only tends to break boxes and spindles, and there is no object gained in reversing a mill in less time than it takes to get the piece back to the rolls. Whether the electric motor will reverse quickly enough to suit very rapid reversing, such as is required for the soft rolls of a plate mill where the slab is very short and the reversals very rapid, has not yet, I think, been tried, but it must be remembered that when the slab is very short the speed of the rolls is low, and this being so rapid reversing is not so difficult as would appear at first sight.

Figs. 1, 2, and 3 are reproduced from records showing the current or power put into the rolling mill motor, also the power required from the power station to roll a 1·45-ton ingot into 4 in. by 4 in. blooms, a 1·35-ton ingot into 2 in. by 2 in. billets, and a 1·8-ton ingot 11 in. by 6 in. girders respectively.

From these diagrams it will be seen how very perfectly the fly-wheel converter averages up the great varying loads on the mill. In rolling 4-in. by 4-in. blooms it will be seen that the greatest load on the mill is some 2,500 kw., while the current taken from the power station is steady at about 600 kw. In rolling down to 2-in. by 2-in. billets it is interesting to see how very much more power is required to reduce the section down to 2 in. by 2 in. as compared with 4 in. by 4 in., the 2-in. by 2-in. billets taking some 60 per cent. more power than the 4 in. by 4 in. The third diagram represents the rolling of 11-in. by 6-in. girders, the power in the mill motor rising as high as 4,000 kw., while the current taken from the power house is represented by about 700 kw. rising to 1,200 kw. while in the finishing rolls. Now that the recording of the actual power required to pull the bar through each pass is so easily and perfectly recorded, any uneven drafting of the rolls will be more easily corrected. The total power used by the rolling mill is accurately recorded by a watt-hour meter on the switch board, and the cost of providing power is accurately known for every section rolled per ton.

Units in mill motor, 69. Units from power house, 94. Efficiency, 73·5 per cent. Units per ton rolled, 52.

FIG. 3.—POWER CURVES FOR 17″ × 18″ INGOT ROLLED IN 19 PASSES INTO 11″ × 6″ JOISTS.

It would appear, then, that to roll, first, 1 ton of 4-in. by 4-in. billets requires 25·4 kw. or 430 lb. steam; second, 1 ton of 2-in. by 2-in. billets requires 38 kw. or 650 lb. steam; 11-in. by 6-in. girders requires 50 kw. or 860 lb. steam. Whether these figures will be improved upon remains to be seen, so much depends on the hardness of the steel and the temperature at which the rolling is carried on. One of the latest mills set to work is the mill at Rombach, which already produces 50 to 60 tons of 3¼-in. square billets direct from ingots of 2 tons in weight, with a current consumption of 22 kw. per ton. From these figures it is to be expected that 4-in. by 4-in. billets will be produced for 20 kw. per ton, or even less. Further interesting data relating to the kws. required to roll ingots down direct into rails, joists, billets, is published in *Stahl and Eisen*, from which it will be seen that to roll

53lb. rails	from	1·4	ingots	70 kw.	are required.
72lb. ,,	,,	1·5	,,	60 ,,	,,
41lb. joists	,,	1·8	,,	56 ,,	,,
86lb. ,,	,,	1·85	,,	53 ,,	,,
4″ & 4″ billets		1·45	,,	29 ,,	,,
2″ & 2″ ,,		1·35	,,	52 ,,	,,

The average production when these figures were taken varies between 12 and 18 tons per hour. It will be seen that the output is very small, the rolling being carried on too slowly to give good results in current consumption. 29 kw. is given for 1 ton of 4-in. by 4-in. billets at the rate of 17 tons per hour, when only 14 tons per hour were rolled in the same mill the current consumption rose to 33 kw. per ton. Whereas at Rom-

Digitized by Google

bach, with 50 to 60 tons per hour of 3¼-in. billets, the current consumption is much more favourable at 22 kw. Whether the electric mill is rolling much or little, the Ilgner converter set is running all the time, and this absorbs about 120 kw.

The disadvantages of the electrical reversing mill are the high capital expenditure, and the electrical losses between the motor driving the fly-wheel converter and the mill motor. There appears to be no inducement to any firm who have to produce their electricity by burning coal directly under boilers to instal a special power station to drive a mill, or even two mills, say a cogging mill and finishing mill, supposing there was a saving in the coal bill, the capital outlay required for the electrical plant would probably counterbalance any possible saving in the coal bill. The great advantage of electrical rolling, in fact the greatest advantage of all, is that the generation of all the power required, for the whole works, is in one large central station.

That electrically-driven mills have made more rapid progress in Germany than in England is partly accounted for by the fact that coal is dearer in Germany than in England. And also that the rolling mills work in conjunction with blast furnaces which produce large quantities of electricity very cheaply with the aid of the gas engine, and without cheap electricity electrically-driven mills will make no headway. It cannot, of course, be said that which pays well in Germany would necessarily also pay well in England, neither can it be said that electrically-driven mills are right for every works, each works must consider their own conditions.

The new mill at Rombach, equipped by the A.E.G. of Berlin, consists of two stands of rolls 32 in. diameter. The two mill motors are capable of exerting 15,000 h.p. at 120 to 160 revolutions. The voltage of each motor is about 600, and the torque is 90 metre tons. The Ilgner converter is drawn by a motor of 2,800 h.p. Four fly-wheels of 25 tons each, making 300 revolutions per minute, are used to equalise the loads. The mill is designed for an output of 60 to 70 tons per hour.

THE MANAGEMENT OF ENGINEERING WORKSHOPS

Manchester Discussion

THE Paper by Mr. Eustace Thomas, which was read before the Manchester Local Section of the Institution of Electrical Engineers last week, and was given in abstract in our last issue (page 580), was followed by an interesting discussion. The Paper itself dealt with some of the general principles by which economy may be obtained in manufacturing works, especially as regards shop routine, lists of materials, drawings, records, &c., and the day work as compared with the piece work or premium system.

In declaring the discussion open, the chairman, Mr. M. B. Field, said a few words emphasising the importance of the subject, which he thought had not been treated of by the Institution before.

Mr. Gunther said, in reference to the comparison of general and specialised shops, he thought that a general shop, that is, not taking every class of work, could be run quite as efficiently in its way as shops which are highly specialised, such as those dealing with small electrical appliances, and so well known that the efficiency comes out really very fine indeed. As to each workman having a drawing or sketch, that goes without saying. In all well organised places he agreed that the drawings should be of as complete a character as possible, fully dimensioned, and wherever possible, if it is a job likely to be repeated, the drawings should carry all leading particulars. He did not quite see that in an ordinary works a routine book was necessary. As a rule, the job that a man had given to him was not the same day after day except in a place making one class of work; but where one man had to do each day the same class of work, or extending same over several days, no doubt a routine book would be very advisable. His firm had considered the question of numeration of tools, drawings, and stock pieces very carefully, and had come to the conclusion that the best thing was to sweep all that away, and to commence with the drawing. Inspection of work at each stage, in the case of stock orders, was often a very difficult matter to arrange. He was afraid that premium and piece work were going out in engineering works. When non-union and unskilled labour was being dealt with it was easier, but when dealing with unions it was rather too big a task.

Mr. H. Bevis (General Electric Co.) thought that the value of a good foreman could not be over-estimated. A good deal of the efficiency of a shop depends upon the foremen, and he thought that they should be employed more exclusively on clerical and administrative work. It was quite a mistake to give them the technical work to do; this should be rather for the tool-shop or drawing-office, and it should be the foreman's chief aim to finish and produce the work under the conditions mentioned in the Paper. He believed that statistics were most valuable, and paid for themselves over and over again if they were utilised properly. Coming to the question of auxiliary stores, he thought that it was an essential thing to have what they called sub or auxiliary stores. The main stores should keep raw material and everything that was common to several departments. The sub-stores should contain only material that was common to the department in which it is used. To obviate the possibility of material not being in the main or sub-stores when required, he believed in having assembly rooms. The whole of the parts were assembled, and the job was never put out to the bench until they had got the whole of the parts. He did not agree with the remark in the Paper: "If the assemblers are on piece or premium work they draw attention themselves to any inaccurate manufacture of parts coming to them." This was, no doubt, some check, but where they were making quantities of stuff, he thought it was then rather too late. The time that they should be checked up was when it was being manufactured in the early stages. If they were only going to send it back when it was found not to fit, it was too late to save the loss.

Mr. Eckstein (Messrs. Eckstein, Heap & Co.) did not believe in making a works rely absolutely upon red tape. As regards the auxiliary stores, he did not quite see what would happen when a job was stopped, and the material had to be returned to the main stores. His idea of an auxiliary store was a place provided in absolute vicinity of the bench, where the workman had a certain amount of material to see definite orders through, but any such auxiliary stores must not be allowed to develop into a number of general stores.

Mr. H. W. Wilson doubted that a certain amount of red tape was desired or necessary; his experience was that red tape accumulated until it became not only unnecessary but undesirable, and several cases had come under his own personal notice where this red-tapeism had caused considerable loss, both of time and money. Systems, whilst very admirable things, could be carried to extremes, and the tendency of all systems, unless continually being checked, was to get too complicated to make a job profitable. It was better, in his opinion, to have a certain small amount of waste going on in small parts than to have the things checked and cross-checked until the cost of the clerical labour was more than the actual manual labour in making them. With regard to the check on times set, the primary object of a manufacturing business was to make a profit, and the two principal items were, broadly speaking, material and labour. Material no one could vary very greatly, but the item where an ingenious works manager had a chance of making a saving was on the labour if he could persuade in some way his men to manufacture a bit more than men in other works. It was thus most desirable to have an expert check on times set.

Dr. C. C. Garrard (Messrs. Ferranti, Ltd.) said that the most important thing about the management of any engineering works was the cost-keeping. The functions of the shop superintendent and foremen must be organised in correlation with the cost department. A proper system of cost-keeping should not only form a basis for estimating, but should serve as a method of management, and transform a merely qualitative works control to a definitely quantitative one. Every job or process should be actually priced in money terms before it is started, and the work controlled during process, so that at any instant the management can know what any process has cost up to that particular moment. Regarding the relative merits of the piecework and the premium bonus systems, he preferred the former. The great objection to the latter was that the workmen got the idea that they did not receive the whole benefit of their extra exertions.

Dr. Garrard then proceeded to outline the system of cost-keeping which he had introduced at the works of Messrs. Ferranti, Ltd. The previous system in use in the works in question had been the "Lewis" system, the foundation of which was the job card which each man received. On one side of the card was the space for the man's time, on the other for the material used. Thus the workman had to go to the stores to draw out material and get it entered on his card. This was, however, very unsatisfactory. Not only did the material for a certain order get divided up in a lot of job order numbers in an entirely fortuitous manner, but a lot of time was wasted by each individual man bothering about finding material. The proper principle was for each man to be supplied with material as fast as he required it, and without him shifting from his machine or bench to find it. It was one of the principle functions of the up-to-date foreman to see that this was done, so that the time lost in going from one job to another was reduced to a minimum. The system he had referred to was a modification of the Lewis system with additions. For every job which was not an absolutely standard article with a constant selling price, an estimate card was made out in the drawing office before the job was put in hand. It was the duty of the works management to

Digitized by Google

see that the article manufactured came within the estimate. Each shop had its own stores, and the material required for every works order number was issued by the stores as requisitioned by the foreman. For standard articles, standard printed requisition sheets were used to avoid waste of time in writing. The material costs for each works order number were kept by the cost clerk who worked in the stores. All issues were entered on cards. Four different-coloured cards were used. These were for stock materials from the stores concerned, castings from the foundry, materials from other departments, and materials from the general stores. Every item went through the shop stores however, and the only object of dividing the cards in this manner was to facilitate departmental book-keeping. The total of the four cards gave the total material costs on any works order number. When the works order number was complete a summary card was made out and filed in the drawing office. This, together with the estimate card and the labour analysis card, were filed together in special drawers like a card index. As regards the labour, each works order number was divided up into a number of job order numbers corresponding to the different processes. Time-work cards or piecework cards were issued to the workmen for each job order number. When each job was finished the sheet was returned to the job clerk, who entered up the total time and cost in his time book. The labour costs were entered up on the job number card and summarised on the labour analysis card, a copy of which analysis was kept in the drawing office record as explained above. As regards stock order numbers, these were treated in exactly the same manner as the works order numbers, and the stock parts when completed went into the stores at the price they had actually cost, and were also debited out on the various works order numbers at the same price. As many similar articles as possible were put through on each works order number. As regards pricing stock parts, these were priced at the actual cost in labour, material, and testing, *plus* shop establishment charges. The shop establishment charges did not include general establishment charges, which remained, more or less, unaltered whatever the output. The shop establishment charges included all shop charges which varied with the output, such as general labouring, supervision, &c., and which were directly under the control of the shop management. These varied with the output, but not so fast as the output. They varied between 40 per cent. and 60 per cent. of the labour cost. All goods made were costed in this manner, and, as an inducement to the reduction of cost, a bonus was paid, based upon the difference between this shop cost and the selling price. In order to be able to control costs of standard articles he had found it a good plan to plot the costs in the form of curves.

Mr. Eustace Thomas replied briefly. With regard to the catalogue numbers, he still thought that the matter of catalogue numbers was rather an important one. They had found in doing a great deal of general work, and having to design special pieces for special apparatus, these were apt to get associated with a particular job, which was forgotten in a very short time. A new draughtsman coming in, and having no recollection of this job, would start and re-design this over and over again, and parts would get multiplied out of all reason. It was quite true, and it was very regrettable, that workmen as a whole had deteriorated very considerably in consequence of the system of manufacture adopted. It was often found that if one relied upon a workman to think out a matter, one was apt to get "left."

WIRELESS TELEGRAPH PLANT AT THE UNITED STATES NAVAL ACADEMY

An article in the *Electrical World*, by Lieut.-Com. W. H. G. Bullard, describes the wireless station at the United States Naval Academy, Annapolis, Maryland, which forms one of a chain of stations on the Atlantic Coast.

The station was established not as a transmitting station for long distance, but rather as a relay station to forward messages from other stations or from vessels. For this reason the power installed was small, the station set having only a rated capacity of 2·4 kilowatts. This power is obtained from a storage battery of 40 cells, giving a normal voltage of 80 volts. When occasion demands, this battery is charged from power obtained from the main power station supplying the Naval Academy with light and heat. The transmitting circuit contains the induction coil, condensers, inductance and spark gap of the Slaby-Arco type. Direct current from the storage battery is led to the primary of the induction coil, and the make-and-break is effected by means of a mercury turbine interrupter, making 1,600 revolutions per minute. With a line voltage of 80 volts, a maximum of about 25 amperes may be used in the primary windings. The condenser consists of seven leyden jars, connected in multiple with a total capacity of 0·014 microfarad. The inductance is a spiral conductor of No. 8 copper wire, consisting of 9·9 turns of a mean diameter of 17 in. The spark gap is a single break between zinc electrodes with a normal length of $\frac{3}{4}$ centimetre and a maximum length of $2\frac{1}{8}$ centimetres.

The receiving device now used is of the De Forest type of electrolytic cell used in connection with the head telephones of the Schmidt-Wilckes make. This cell uses a Wollaston wire, glass jacketed, and of 0·006 in. diameter, as the anode, and a platinum wire as the cathode, in a solution of pure nitric acid. In connection with this cell is used a primary battery, with potentiometer. Associated with the detector in the receiving circuit is a capacity 0·005 microfarad with a variable inductance of two coils of copper wire wound with 500 turns on each coil. The aerial is a loop of a total length of 1,054 ft., consisting of four wires of phosphor bronze. It has a horizontal length of 100 ft. and a vertical length of 166 ft. The aerial is coupled direct to the transmitter inductance and has a natural wave length of 335 metres. The wave length ordinarily used is 318 metres for the lower hump and 420 for the upper. With the coupled circuit for 425 metres, the lower hump is 348 metres and the upper hump is 500 metres.

In the Department of Electrical Engineering at the Naval Academy, and entirely distinct from the working station described above, is installed a 5-kw. Stone wireless telegraph plant. This is used for the sole purpose of demonstration and for the instruction of midshipmen in their electrical course. The power is obtained from the Academy power plant, direct current of 110 volts being converted by means of a motor generator into an alternating current of the same voltage.

The distinguishing features of the Stone set are the multiple arrangement of the transmitting inductance, the series key for making signals, the spark gap and the "weeding-out" circuit of the receiver. The set is inductively coupled to the aerial, and consists of four coils in parallel for the primary, connected inductively as an air transformer to four coils in parallel in the secondary. One terminal of each secondary coil is connected to the aerial through a loading coil, and the other to ground. With the high frequency of the alternating current - 120 cycles per second—and the large inductance, this is necessary to produce the short wave-length desired. In this system, the circuit is made and broken to produce the proper signals on the high-potential side of the induction coil. This obviates breaking the heavy current of the primary and the consequent arcing and burning of the key contacts. The high-potential side is made and broken in both leads of the mains by a line of contacts in series. These contacts are actuated by small electromagnets, wired in series with the low-potential current of 110 volts. Inserted in this circuit is a resistance to reduce the current through the electromagnets to about one ampere. The key that operates the series keys is on the operator's table, and is a simple telegraph key whose terminals are connected to a small condenser. Making and breaking this auxiliary current has the effect of making and breaking the line on the high-potential side of the induction coil. The spark gap consists of a series of parallel brass rods through which the spark occurs, and it can be regulated by a rod on one terminal which slides over them, cutting out more or less of the rods. To remove the metallic vapour formed at the spark, a strong blast of air is blown over it from an auxiliary blower. The receiving circuit contains the usual inductance and capacities, and normally consists of three circuits, all inductively connected. The third circuit contains the electrolytic detector and head telephones. The middle circuit is termed the "weeding-out" circuit, and is used when sharp tuning is necessary to cut out interference. All the capacities are of the variable sliding type, and the primary inductance of the sliding bare wire type. Arrangements are made for varying the mutual induction of all the circuits by moving one inductance in relation to the other in each circuit. The condenser is of the glass-plate tinfoil type, made up in four sections, one being connected to each of the four primary circuits of the oscillating transformer. Its dielectric is castor oil, which is used to reduce the violet discharge at the edges of the tinfoil on the glass plates.

In connection with the instruction of midshipmen, there is installed in the Department of Electrical Engineering another small wireless telegraphy plant of no particular make or system, but containing all the elements required for the proper sending and receiving of signals. The power is transformed from the Academy plant voltage to a lower voltage of continuous current by a small rotary transformer. This direct current is used with an ordinary induction coil with a hammer make-and-break; a battery of leyden jars forms the condenser, and a helix of copper wire the inductance. For receiving, a small incandescent lamp is used as a detector, the filament being removed and the interior filled with nitric acid introduced to cover the platinum points of the leading-in wires. This is used in connection with an ordinary telephone receiver.

A new wireless plant of 20-kw. capacity has been contracted for by the Bureau of Equipment, Navy Department, to be installed at the Naval Academy, which will make one more plant that can be utilised for instruction and demonstration purposes, and an installation of wireless telephones will shortly be made to aid in the general course of instruction.

THE ELECTRICAL EQUIPMENT OF AN AMERICAN PAPER MILL

THE accompanying illustrations show the arrangement of American electric motors of direct-current and alternating-current types installed in the Watab Paper and Pulp Mill at Sartoll, on the Mississippi River.

Power is supplied by a hydro-electric station located near the centre of the river, adjoining the grinding-room. This latter contains a number of grinders operated directly by water power from special turbines, but all of the other power is electrically transmitted to the various electrically-driven machines in the different departments. The main mill building, which is of reinforced concrete, includes a machine-room and basement 72 × 250 ft., and a beater room and basement 40 × 122 ft., also a wood-room and basement 36 × 70 ft. There is also a boiler-house 58 × 72 ft., and a pulp mill 32 × 152 ft., as well as a pump-room 20 × 70 ft. The boiler-room contains two Stirling water-tube boilers which furnish steam for heating the building and for drying the paper. The power-house is 72 ft. long and 32 ft. wide, and the water is supplied by a dam 600 ft. long, thrown straight across the river, and affords a head of approximately 17 ft. The power-house and grinding-room form a part of the dam, and the remainder consists of gates and spillway of the ordinary rock filled crib construction.

The electric power generating installation includes three 600-kilowatt three-phase 60-cycle 480-volt alternating-current revolving field generators, each direct connected to a sextuplex water-wheel operating at a speed of 200 revolutions per minute. The exciting current for these generators is supplied from a 75-kilowatt 120-volt direct-current generator, coupled to a single water-wheel, or from a motor-driven exciter of the same capacity. There are two motor generator sets in use, each consisting of a 250-kilowatt 240-volt direct-current generator coupled to a 480-volt synchronous motor to supply current to the variable speed motors in the machine-room.

It is stated that the alternating system was adopted as being best suited to withstand the rigorous requirements of paper-mill work, and least liable to give trouble with motors when located in moist places. The current is distributed through a 13-panel switchboard, arranged with wattmeters and ammeters, so that an accurate log may be kept of the power required by each separate department. Thirteen feeder circuits carry current to 51 constant speed alternating-current induction motors, and to eight variable speed direct-current motors of the Allis-Chalmers' design and construction.

The variable speed shaft of each of the two 154-in. Beloit machines is driven by a 250-h.p. variable speed direct-current motor, coupled directly in the centre of the shaft. This motor operates at a speed of from 370 to 540 revolutions per minute, corresponding to a paper speed of from 300 to 600 ft. per minute. The entire speed variation is accomplished by means of resistance in the shunt field of the motor. The field rheostat has 138 steps, and a change of approximately 2 ft. per minute in paper speed is obtained for each step. This is a much finer variation than can be obtained easily through the medium of any mechanical speed-changing device; it must be borne in mind, too, that the changing of speed is accomplished without any loss of time, as the controller is located on the machine-room floor, adjacent to the drying rolls, and the movement of the controller handle by the attendant occupies little more than a second.

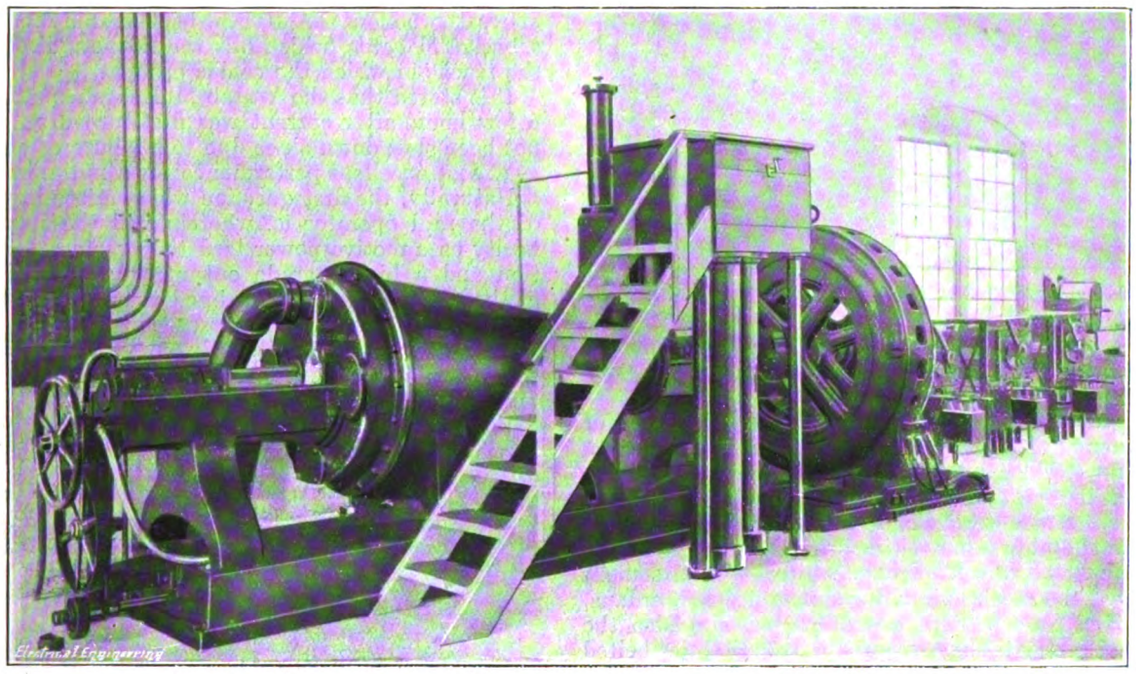

Fig. 1.—"Majestic Jordan" Machine, driven by 150 h.p. Induction Motor.

At the head of each machine the re-winder is driven by a variable speed 30-h.p. direct-current motor, having a speed range of 2 to 1. Two 7½-h.p. motors of the same type, with 25 per cent. speed variation, operate the shakes of the two machines. The only other direct-current motors in the mill are two of 5-h.p. capacity, with a speed range of 2 to 1, which drive special cutters located in the machine-room basement. At the wet end of each machine, in addition to the shake, the group consists of a save-all, driven by 5-h.p. back-geared induction motor, suction pump driven by 30-h.p. geared induction motor, fan pump with 40-h.p. direct-coupled motor, machine pump with 7½-h.p. geared motor, and machine chest agitator and flat screens driven by a 30-h.p. belted motor. To this group belong

Digitized by Google

also the broke beater, driven by a 40-h.p. belted motor, and the broke beater pump, driven by a 40-h.p. direct-coupled motor. The beater-room is equipped with six beaters and two Majestic Jordan machines. The beaters are driven in pairs, one right and one left, by three 100-h.p. motors located in the basement. These motors have their shafts extended both ways with pulleys on either end; outboard bearings are also provided to ensure rigidity and freedom from belt slippage. Belts connect the motors directly with the beater pulleys.

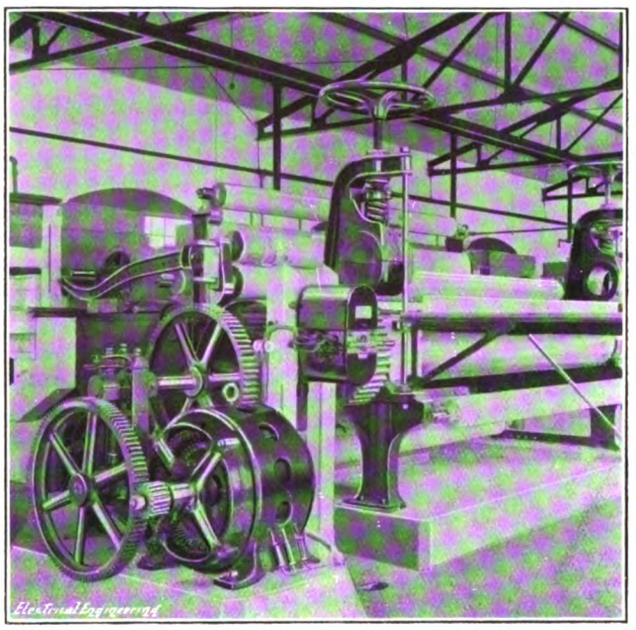

Fig. 2.—10 h.p. Motor backgeared to Wet Paper Machine.

A unique feature of the mill is the electric drive for the Jordans, each of which is directly coupled to a 150-h.p. motor, running at 312 revolutions per minute. As shown in Fig. 1, the base of the Jordan is extended to receive the motor, which is arranged to slide on rollers as the plug is moved in or out by means of the regulation hand wheel. In the beater-room basement are located the stock pumps for supplying the Jordans, each driven by a 7½-h.p. geared motor, and also the Jordan chest agitators driven by two 15 h.p. belted motors. The controllers for starting and stopping all motors governing the supply of pulp to the beaters and the Jordans are located on the beater-room floor, so as to facilitate rapid handling of stock.

The pumps controlling the water supply and those for handling the ground wood pulp are located in the pump-room, the entire water of the mill, outside of the boiler feed, is obtained through three 6-in. centrifugal pumps, each direct connected to a 40-h.p. motor. Two centrifugal pumps for pumping pulp from the grinders to the flat screens in the wet machine-rooms are located in a pit beneath the pump-room. Each of these is direct connected to a 50-h.p. motor. In this room are also the centrifugal Decker chest pump, direct coupled to a 40-h.p. motor, the triplex pressure pump for grinders driven by a 40-h.p. geared motor, the triplex back-off pressure pump driven by a 7½-h.p. geared motor, and the silver screen driven by a 5-h.p. back-geared motor.

The wet drives are located in the wet machine-room, also two Deckers and twelve flat screens. The wet machines are each driven by a 10-h.p. back-geared motor, as shown in Fig. 2. The flat screens, which are located immediately behind the wet machines, are shown in Fig. 3. They are driven through friction clutches connected to a line shaft by means of the mitre gear, this line shaft being direct coupled to a 100-h.p. motor. The Deckers are driven by belts from the wet machine shaft. A machine shop, adjacent to the wet machine-room, is driven by a 10-h.p. belted motor.

There are six barkers and a 60-in. log saw, with the necessary conveyor in the wood-room equipment. Some of these machines are shown in Fig. 4. The logs used for making pulp are taken from the river to the saw by a log haul, which is driven by a 5 h.p. back-geared motor. The saw and live rolls are direct coupled to a 30-h.p. motor, the coupling being of sufficient weight to act as a flywheel, and thus reduce the actual power required for sawing. The sawed wood is carried to the barkers by a conveyor driven by a 10-h.p. back-geared motor; this same motor also drives a splitter. Each of the barkers are driven by a 7½-h.p. direct-coupled motor, the iron base of the barker being cast with a pedestal to receive the motor. The prepared wood is carried to the grinding-room by a conveyor driven by another 10-h.p. back-geared motor. A shaving fan, driven by a 40-h.p. belted motor, blows the chips from the barkers directly on to the boiler grates. What additional coal fuel is required is carried in hoppers above the boilers. A 10-h.p. back-geared motor drives a basket elevator, which fills the hoppers directly from the trucks in which the coal is brought.

It is stated that the Watab Mill began making paper a few hours after current was first turned on, and has not been shut down since due to a failure of equipment—a most excellent performance for a mill of this kind.

Naturally, the first question which arises in the mind of the mill operator is, wherein will the use of electricity as a motive power lead to lower cost of production and a higher grade output. As a result of use of the motor drive, it is claimed that there is not only reduction of transmission losses, but greater reliability and greater elasticity, also reduced cost of maintenance, as well as a steady speed throughout the mill, besides tending to far greater cleanliness.

With regard to the reduction in the transmission losses, actual tests show that these losses, in the case of mechanical drive, vary from 40 to 60 per cent. of the power delivered at the engine or water-wheel shaft; 50 per cent. being a very fair average. This figure, of course, does not apply to the grinders or the beater shaft when driven direct, as is usually the case. It is claimed that, in comparison with this, with the electric system power can be transmitted from the shaft of the prime mover to the shaft of the driven machine, with an average loss of from 20 to 25 per cent., from 3 to

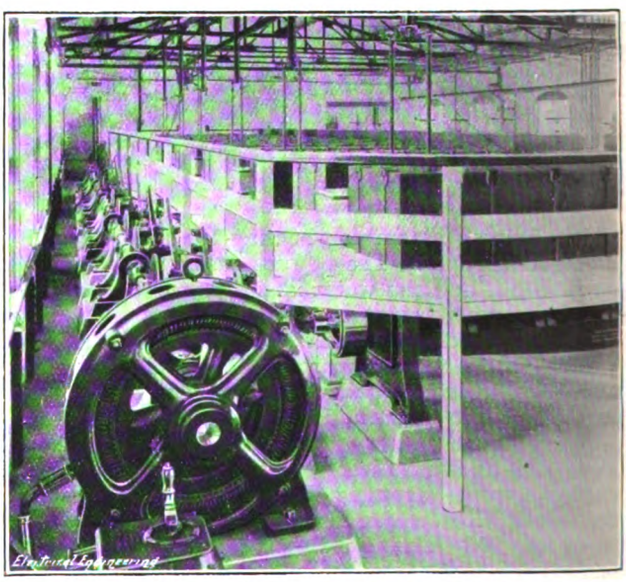

Fig. 3.—100 h.p. Motor driving Flat Screens.

Digitized by Google

5 per cent. of this being in the wiring, and the balance in the generators and motors. Also the loss is reduced to this low point regardless of the complexity of the system.

From the above it is clear that in the power transmission alone a saving of from 15 to 40 per cent., depending on the conditions to be met with in each individual case, can be effected by the use of the electric system. A modern two-machine mill, with prevailing tendency towards large size machines, will require, outside of the grinders, from 1,500 to 2,000 h.p. Assuming the minimum saving of 15 per cent. on this, we shall have a net gain of from 225 to 300 h.p., which will represent a considerable annual saving in expenses. It is maintained that in a steam-driven mill this saving would be represented by the decreased consumption of fuel; in a mill where water is the prevailing power the saving will appear in the additional volume of water available for grinding pulp, or for extensions; and in these days pulp is a very valuable asset, which can always be marketed to mills that are unfortunate enough not to possess sufficient water power to grind their own pulp.

That there is greater reliability with electric drive than with the complicated combinations of shafting and gearing often seen in paper mills is obvious when we

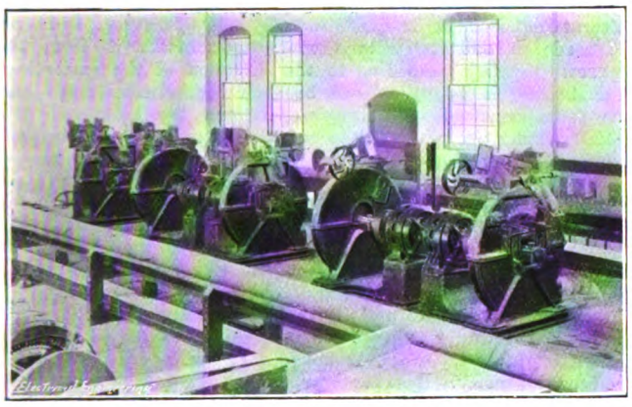

Fig. 4.—Electrically-driven "Barkers."

consider the reduction of the number of intermediaries between the machine and the prime mover.

Such motor troubles as are heard of from time to time are in nearly every case directly traceable to poor engineering in laying out the installation, or the negligence on the part of those employed to look after the electrical apparatus.

With electric drive it is also claimed that there is greater elasticity, and in this expression is included the greater ease of providing power equipment for extensions. Another point of elasticity in electric driving for such work as paper mills is that one may distinguish between the different types of power service required throughout the mill, and to treat each individual case on its merits and in the manner calculated to secure the highest efficiency of operation, utilising constant or variable speed motors, as may be most suitable. In the old days it was always a case of belting, but with the electric system we can either direct connect, gear, or belt the motor to the driven machine, as may seem best. In general, for paper mills, it is better to direct couple wherever this can be done without too great an investment in the motor by reason of the necessity for very slow speeds. It may be said that the practice usually followed in up-to-date mills is to direct connect the centrifugal pumps, Jordans, barkers, log saw, and variable shaft of the paper machines; gear all duplex or triplex pumps, rotaries, calenders, and wet machines; gear or belt the conveyors, rag dusters, and cutters; and belt the beaters, elevators, and all group drives. The grinders are usually direct coupled to the water-wheel shafts in water-driven mills, although there are some engineers who favour driving these also by direct-connected motors.

With regard to reduced cost of maintenance, in an electrically equipped mill, where shafting is practically eliminated, it is only necessary to see that the bearings of the motors and generators are properly lubricated, and, in case the equipment is of the direct-current type, to keep the commutators in order. Burn-outs in the windings of the motors are now practically unheard of, but even if they should appear, the motor can be repaired without much expense. The services of at least one man and possibly two or three are saved outright, and there is less expense for supplies.

The steady speed which is obtainable throughout the mill with electric drive is another of the many advantages. It is claimed that electric driving produces ideal conditions for the paper machine, which is the very heart of the mill, and the successful operation of the auxiliary apparatus is of no avail if there is trouble at this point. Nothing contributes so much to satisfactory operation as a steady speed, which can at the same time be readily varied, and uniform temperature in the steam which is used for drying. As will be seen, both of these requisites are possessed by the electric system.

By means of the variable speed motor the speed can be varied at the will of the operator over a very wide range, without a serious alteration in the motor efficiency. One of the most important features of the speed change lies in the fact that the successive increments of the change are very small; each step on the controller means a change of only 1½ to 2 revolutions on the motor, or on the variable speed shaft to which the motor is direct coupled. The speed can be varied over the entire range without a shutdown, which means that the machine tender can change from one grade of paper to another, no matter how great a difference, without stopping the machine. The difficulties of maintaining a constant speed, when the machine is driven from one engine operated under a varying steam pressure and varying load, are too well known to require more than mention. The clumsy and inefficient mechanical speed changers, step pulleys, and cones are always a source of trouble, and, compared with electric transmission, are the makeshift of a past age. It is held that the single objection raised by some manufacturers to the electric system is with regard to the economy of the drive on the paper machine itself. They contend that as long as it is necessary to use steam for drying it would be better to drive the machines by engines and use their exhaust rather than drive by motors and dry by live steam. In a consideration of this point some engineers divide the mills into two classes: those whose initial power is water, and those whose initial power is steam. Even the most ardent advocates of the use of steam engines and exhaust steam will admit the superiority of electric drive in the case of mills of the first class, where ample water power is available for all purposes, for there can be no question that the generation of electric power from water is cheaper and more efficient than the generation of steam power from coal. The only argument, therefore, is with respect to mills of the second class, which must produce all or a part of their power from steam. Many such mills, partially steam driven, could be placed in the water power list by the adoption of the electric system, the power thus saved being equivalent to that produced by steam. Admitting, for the sake of argument, that in mills of the second class it is more economical to use engines on the machines—which contention is open to dispute—the many advantages of the electric drive, as described herein, are more than sufficient to outweigh the

Digitized by Google

possible saving in fuel. It is claimed that there is no reason why the exhaust from the main engines driving the electric generators could not be used for drying, if desired; and if this is done the question of economy is wiped out entirely.

Another contention which has been advanced by paper manufacturers who are using electric driving on their machines and live steam for drying, is that the use of live steam permits of maintaining a constant temperature on the dryers, resulting in a uniform sheet of paper of high finish, a condition which cannot be as easily secured by exhaust steam on account of the varying pressure in the line. If the mill be driven by water power, no engines whatever will be required; if by steam, the engines will be used solely to drive the electric generators in the power-house. It is maintained that in either case the drying will be done by live steam taken directly from the boilers, and brought down to the proper pressure through a reducing valve. A constant pressure is assured by this method, which means a uniform temperature in the dryers of the machine. There is no reason in a steam-driven mill why the exhaust from the engines driving the generators cannot be used for this purpose, if desired, but if the drying is done with exhaust steam, it is almost out of the question to maintain a uniform temperature.

There is also with electric drive a great saving in space as doing away with so much shafting, &c. As the motors are mostly direct-geared or coupled, very little space is required by them, thus permitting the placing of the various machines close together, and at the same time affording ready access to all. As the result, a large floor space is available for the storage of stock, in such a manner as to afford ready access, not only to the stock itself, but also to adjacent machinery.

Another feature of importance with electric drive is the decreased chance of injury to employees. The greater cleanliness for electric drive is also of particular importance in a paper mill.

VOLTAGE REGULATION IN ROTARY CONVERTERS

IN the course of a Paper by Mr. C. W. Stone, read recently before the American Institute of Electrical Engineers on recent development in synchronous converters, or, as they are more generally termed rotary converters, the author dealt with the subject of voltage regulation. With a synchronous converter, as is well known, it is not possible to regulate the direct voltage of the machine by means of the field rheostat, as is done with a direct-current generator, without changing the power-factor; for the ratio between the impressed alternating voltage and the direct voltage is fixed by the design of the machine. Hence where voltage regulation is necessary, as for lighting work, charging storage-batteries, &c., some means of changing the impressed alternating voltage is necessary. Some of the different methods used to accomplish this result were briefly described as follows:—

On the step-down transformers used with the converter, taps can be placed either on the primary or the secondary side, and switches used to transfer from one tap to another. This scheme has many objections and is seldom used now. If the taps are on the primary, oil-switches would have to be used if the voltage were at all high. Such switches would be practically out of the question. If the taps are on the secondary, a dial-switch can be used, but only with the smaller size machines, as it is difficult to build a dial-switch to handle large currents satisfactorily except at prohibitive expense. This method is also objectionable as it means fluctuation in the lights whenever the switch is moved to a different tap.

The common way of obtaining control of the voltage in railway work is to insert in the leads from the secondary of the transformer a reactance, thus causing an artificial drop in the impressed alternating voltage. This method, while simple and effective with the limited ranges in voltage required for such work, would not be applicable for large ranges in voltage. Too much reactance may cause pulsation troubles, and it also has a bad effect on the entire system.

The arrangement in most general use to-day is to connect between the secondary leads of the transformer and the synchronous converter an induction regulator, by which it is possible to obtain almost any range of voltage within the capacity of the machine. This scheme of operation is in such general use that it will not be necessary to describe it in detail. The principal objection to this arrangement is that another piece of operating machinery is used with each synchronous converter outfit, increasing the cost, requiring valuable floor space, and making it necessary to open the secondary leads from the transformer, a complication with large low-voltage machines.

The next development in this line took place abroad, where an entirely different scheme was used. A few machines of this type have also been built by one of the large manufacturing companies in this country. This method makes use of an alternating-current booster or "bucker," mounted on the same base with the synchronous converter. The field has the same number of poles as the converter, and the armature is mounted on the same shaft as the synchronous converter armature. Alternating current is generated in this armature, and can be made to add its voltage to or to subtract it from the impressed voltage according to the direction of the excitation. This booster is usually placed between the collector rings and the main armature of the converter, and the taps from the collector rings are connected to equidistant points of the booster armature; similar points on the booster armature are connected to the synchronous converter armature, thus placing the two in series, separate and distinct windings for each phase being used. The principal objections to such an arrangement are that here again we have an additional operating machine, as in the case of an induction regulator. Extra weight is added to the shaft between its points of support. The ventilation of the converter armature and its accessibility are impaired. Any serious trouble with this smaller machine results in the dismantling of the main synchronous converter in order to repair the small booster. Another way to construct such a machine is to make it a revolving field machine, mounting the field on an extension of the shaft beyond the bearing of the collector-ring end of the synchronous converter. As the armature is stationary, the leads from the secondary of the transformer are led directly to this winding, and from this winding to the collector rings of the synchronous converter.

This arrangement has the twofold advantage of being accessible, and not interfering with the ventilation or accessibility of the synchronous converter. This booster can be applied to any standard converter, and, being overhung, it is possible to carry a spare machine which can be placed in position quickly and without interfering with the body of the main synchronous converter.

The next development is very radical and is unlike any of the other schemes used. It was first proposed by J. L. Woodbridge some time ago. It has been known for some time that the ratio of conversion between the alternating current and direct current sides of a synchronous converter could be changed by varying the width of the pole-face. Each field pole is divided into three sections on each side of which are two windings. One of the windings on each section is the main shunt winding, and the other is the regulating winding. All the main windings are connected in series and excited in the ordinary manner. The regulating windings, however, are connected differently. The windings on the two outer sections of all poles are connected in series with one another, and the windings of all the central sections are connected in series with one another. The voltage of the direct-current side of the converter is increased by exciting all the outer sections in a direction to assist the main shunt field, and the middle section an equal amount in opposition to the main field. If both these windings are excited in the opposite direction the direct voltage will be lowered. All that is needed in this arrangement is a field rheostat in the regulating field circuits in addition to the main field rheostat ordinarily used. With machines arranged this way the power-factor can be held constant at all loads, yet all the range in voltage desired can be obtained.

Digitized by Google

Since this method was proposed, another and still simpler method has been brought out. This scheme was proposed by Mr. J. L. Burnham. Instead of making each pole with three sections and with two windings on each, only two sections are used. On each section only one winding is used. The large section corresponds to the main shunt winding on an ordinary synchronous converter, while the regulation is obtained entirely by changing the excitation of the smaller section, exciting it in one direction to boost the voltage, and in the other to lower the voltage.

MR. POULSEN ON WIRELESS TELEPHONY AND TELEGRAPHY

At the London Institution on Wednesday, the 15th inst., a large audience listened to Mr. Valdemar Poulsen's account of recent progress in the application of the so-called "undamped" electrical waves to wireless telegraphy and telephony.

The lecture was read by Mr. Nevil Maskelyne, and began with a sketch of the differences between the sustained waves used by Mr. Poulsen and the intermittent waves used by Mr. Marconi and others. The relative advantages of sustained over

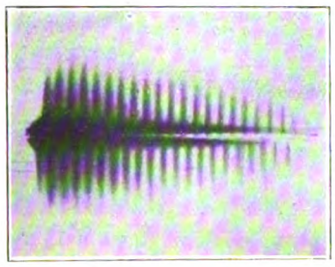

Fig. 1.—Oscillograph of Damped Oscillations Without Antenna.

intermittent waves for the purposes of wireless telegraphy were set forth by Mr. Poulsen at length. In his view, though the spark waves rendered excellent service in the introductory stages of the development of wireless telegraphy, yet, as a means for widely-extended intercommunication they are entirely unsuitable. The only thing to be said, in any case, in favour of spark telegraphy is that there is no necessity for the costly network of wires required for line telegraphy. A spark telegraph station resembles a signal gun; and just as a gunshot communicates vibration to everything around it capable of motion, so the electric waves produced by a spark communicate more or less of their energy to everything they meet that is capable of conducting electricity. Now each spark must possess initially sufficient energy to bridge the whole distance to be traversed, and this amount of energy must be liberated in the very short time of the life of the spark. Hence the process must be explosive in character; and this being so, it follows that it cannot fail to produce an enormous effect at short distances, and, consequently, there are great difficulties in avoiding interference.

It was not until the much-coveted continuous oscillations were produced that wireless telegraphy became really efficient from a practical point of view. Here the lecturer summarised the discoveries of Duddell and himself, which led up to methods of producing powerful oscillations, and some very good oscillograph photographs were thrown on the screen in illustration of

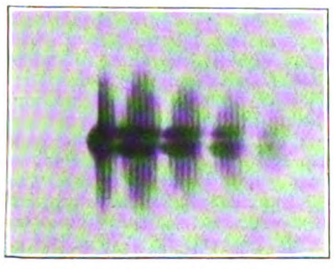

Fig. 2.—Oscillograph of Damped Oscillations With Antenna.

the physical difference between damped and undamped oscillations. Figs. 1, 2 and 3 show several oscillograph records. Figs. 1 and 2 are pictures of spark-produced oscillations of 1,680 metres wave-length. In Fig. 1, the condenser circuit has no antenna coupled to it; in Fig. 2 an antenna is in use, with a coupling of closeness about 14·5 per cent. Fig. 3 shows a record made by sustained oscillations produced by the hydrogen arc, the wave-length being 3,000 metres. This photograph shows very clearly that the discharge in one direction is more intense than that in another, a fact arising out of the necessary asymmetry of the arc method of generating oscillations. These photographs are produced by means of the "tube-oscillograph," which is a "vacuum-tube" containing air at a pressure of the order of a millimetre of mercury, and having two equal axial electrodes, of straight aluminium wire, nearly touching. The negative glow on the cathode is photographed, and when the tube is in an oscillatory circuit the negative glow shifts, of course, to and fro from one electrode to the other. It may be mentioned that the rotating mirror used for observing these high-frequency oscillations is run at about nine or ten thousand revolutions per minute.

The lecturer proceeded to explain a special feature of wireless telegraphy by means of continuous waves is the possibility of numerous stations operating simultaneously within the same area. Another characteristic and important advantage of the new waves, and one which is, from a physical point of view, intimately connected with the absence of interference, is that the continuous waves are less weakened by their passage through space than are the spark waves. This may be understood by remembering that the spark waves influence, to some extent, all electrical conductors that they meet. Continuous waves, however, only give up energy when they meet with conductors that have the same rate of oscillation as themselves. The continuous-wave system of wireless telegraphy is thus, *par excellence*, a long-distance system. A third advantage of the continuous waves lies in the fact that they can be made of small intensity, and yet, because of their persistence, convey to a distance in say, a tenth of a second, the same amount of energy as is conveyed by

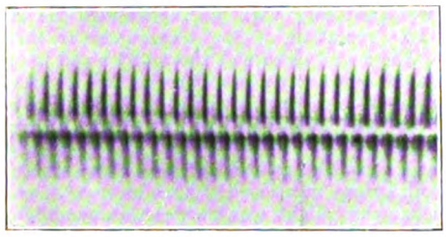

Fig. 3.—Oscillograph of Undamped Oscillations.

a few very intense sparks. Thus, while the spark telegraph for long distances must operate with a tension of from 50,000 to 100,000 volts, the new system requires only 2,000 to 3,000 volts for the same distance. This brings great advantages in respect of reducing insulation difficulties.

Turning to wireless telephony, the lecturer summarised previous attempts at wireless telephony, and then gave a very brief account of his own successes. Readers will best understand the method most recently used by referring to Figs. 4 and 5. The microphone is in a circuit inductively coupled to the antenna and the generating circuit; and the variations of the resistance of the microphone, by modifying the induced alternating current through it, react on the antenna and similarly modify the stream of radiation from the antenna. This causes similar variations in the oscillations produced in the detector circuit, in the rate of heat development in the detector *D*, and in the thermo-electric current through the telephone *T*. The microphone is usually a compound affair, consisting of several ordinary microphones in series, as in Fig. 6. In this way phonograph music played in Berlin has been heard at Lyngby, near Copenhagen, a distance of 460 kilometres (290 miles), and speech has been transmitted distinctly from Lyngby to Esbjerg, a distance of 270 kilometres (170 miles). Mr. Poulsen remarked that he did not at present intend to telephone across the Atlantic. Telephony without wires becomes mainly of importance when comparatively short distances are concerned, where the safe reproduction of speech does not demand any sacrifice of simplicity in the apparatus. As regards interference, the lecturer

Digitized by Google

said that there is no doubt that a multitude of voices can find their way through space in all directions without mutual disturbance, every voice speaking by means of its "ether-tone," with the particular person addressed. Wireless telephony, he continued, has probably good prospects in another direction. It is well known that telephony through submarine cables presents great difficulty, and although considerable progress in this domain has been made during recent years, speech can as yet be transmitted only through short cables. In this respect wireless telephony will probably fill a vacant place, principally on account of freedom from that distortion which limits transmission of speech through cables.

The lecture closed with the old Latin tag, *Suaviter in modo et fortiter in re*, and then the lecturer gave a demonstration of wireless telephony between the lecture table and a distant point of the room.

Apart from the telephonic apparatus, a quantity of new telegraphic apparatus was on exhibition. Two items of great interest were a machine for automatic transmitting and one for quick receiving. The automatic transmitter produces dots and dashes in the waves radiated from the aerial by merely closing a circuit inductively coupled with the aerial. Such a closed circuit has, when the coupling is close, very considerable oscillatory currents induced in it, so that in this transmitter the coil is made to rotate through positions of maximum and zero coupling, and is closed or opened only when passing through the zero coupling position. The operation of the transmitter is thus perfectly sparkless. The actual closure of the rotating coil is controlled by the perforated paper tape run through the transmitter, dots being translated into short periods of closure and dashes into long periods. The tape exercises its control through an ingenious mechanism, of which the principal feature is a horizontal balance lever, rapidly rocked by the motor that drives the rotating coil before mentioned. This lever catches on another lever, which makes slight movements corresponding to the perforations of the tape, only when a perforation is passing the

mechanism, and thus a very broad spring contact is powerfully operated. This trouble is all necessary because currents of 30 to 50 amperes of high frequency may circulate through the closing contacts. The transmitter can send 200 words per minute. Unfortunately, the best of the printing receivers can record at only 120 words per minute. This particular receiver formed the second item of great interest among the apparatus shown. It consists of a thread galvanometer, in which the current from a thermoelectric detector passes along a fine wire strung in a strong transversal magnetic field. The deflections that occur allow a narrow beam of light to pass the instrument and fall on a moving sensitive strip. The exposed tape passes immediately through developing and fixing baths, and may be exposed

to daylight five seconds after the receipt of the signals. There were also on view a few modern powerful oscillation generators. Fig. 7 gives front and back views of the largest standard apparatus, which produces 1 to 1½ kilowatts of oscillatory energy, and is suitable for transmission to distances of a thousand miles.

The Chicago Drainage Canal Power Plant.—According to the *Western Electrician* (Chicago), a commencement was made on March 23rd of the supply from the power station on the Chicago Drainage Canal at Lockport, which was described in Electrical Engineering, April 2nd, page 217. The 44,000-volt supply from the power house is transmitted to a sub-station at Western Avenue, Chicago, and from thence cables are taken to the various existing stations, and is principally used for street arc lighting. In one of these, which already contains alternating-current plant, step-down transformers have been put in, and the old steam plant retained as a standby. In the three existing continuous-current stations, the old arc-lighting machines are now driven from a countershaft by large synchronous motors connected directly to the 12,000-volt feeders. A series of new transformer sub-stations is also being established. Each will be equipped with three 250-k.v.a. 11,500-4,250-volt single-phase transformers. The primaries will be mesh-connected, and the secondaries in star, with eight 50-light circuits in parallel on each branch.

A New Dictionary of Engineering Biography.—In "British Engineers and Allied Professions in the Twentieth Century: Contemporary Biographies," Messrs. W. T. Pike & Co., of Brighton, have published a handsome volume of moderate size. To attempt to compile the biographies of "British Engineers" would, in itself, involve a somewhat voluminous publication if it were to be at all complete, so that when we find "allied professions" included in the scope of this work, it is not surprising that many eminent members of the profession are missing. In fact, it would be an interesting calculation to make, on the basis of the present volume, as to the number of similar volumes which would be necessary to give adequately contemporary biographies of British engineers and the allied professions. In the present edition there are some 700 biographies, all, with the exception of a few, accompanied by photographs. At the beginning there are also a number of engineering articles of a general character, including one by Mr. W. M. Mordey on "Electrical Engineering," and another by Sir John Wolfe Barry, K.C.B., on "Standardisation in British Engineering Practice," in addition to short histories of the Institutions of Electrical, Civil, and Mechanical Engineers, and other engineering societies. The biographies include a good number of electrical men and in all cases the careers and present occupations and distinctions are given with commendable brevity, and, so far as we have checked them, with accuracy. The work is a subscription publication, and a second edition is to be prepared.

ELECTRIC HAULAGE OF CANAL BOATS

A PAPER read by Messrs. L. B. Stillwell and H. Putnam before the American Institution of Electric Engineers last month described the results of tests conducted by the authors during the autumn months of 1907 on a section of the Lehigh Canal, Pennsylvania. The object of the tests was to determine:—(*a*) Pull required to propel canal boats at various speeds and with varying numbers of boats in tow; (*b*) the relative merits, for the purpose contemplated, of locomotives supplied by trolley and operating upon a track of 42-in. gauge,

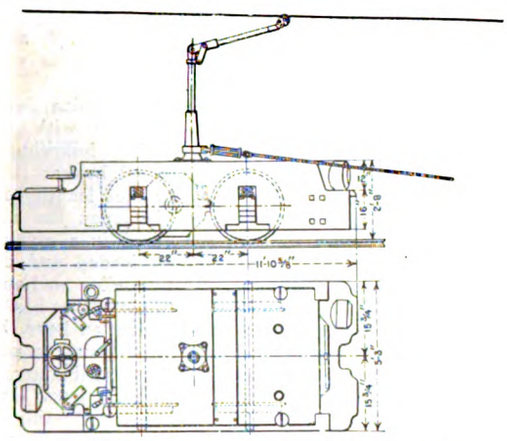

Fig. 1.—Mining Locomotive No. 15.
Equipped with two 28 H.P. Motors.

and a mono-rail system; (*c*) the best speed and length of tow as fixed by physical conditions. The upper section of the canal, on which the authors' tests were made, is equipped with the "Locomotive System." On this section an ordinary mining locomotive is used. Two locomotives were tested, each weighing under test conditions 16,000 lb. without testing instrument and crew. Each locomotive is equipped with two direct-current motors of 28 h.p., operating on 500-volt trolley circuits. The locomotive wheels are 28 in. in diameter, and gear ratio is 4·6 to 1. The wheel base is 44 in. The outline drawing of this locomotive is shown in Fig. 1. The locomotives were operated on a track of 42-in. gauge, and ballasted on the river section with broken stone, elsewhere with gravel. Forty-pound rails were used. The track was uneven and comparatively rough. On this section, two levels of the canal, aggregating 5,600 ft. in length, were in the open river exposed to the river currents. The voltage of the trolley circuits was varied to obtain various towage speeds.

Another section of the canal was equipped with the "Mono-rail System." On this section three traction machines or "Tractors" were used. Two of these tractors (Nos. 1 and 2)

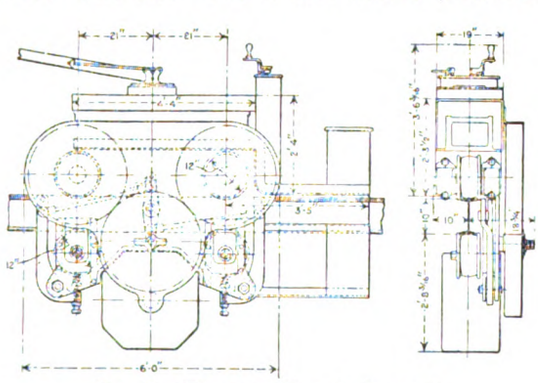

Fig. 2.—Tractors Nos. 1, 2, and 3.
No. 1 and 2 each equipped with one 40 H.P. Motor.
No. 3 equipped with one 25 H.P. Motor.

were manufactured in America. The electric equipment of each comprised one direct-current 40-h.p. motor. The gear ratio was 5·78 to 1; diameter of wheels 12 in., and length of wheel base 42 in. The construction is illustrated in Fig. 2. The ratio of leverage on lever wheels was 4·7 to 1; that is to say, the lower wheels are pressed upward against the lower face of the rail with a force 4·7 times the drag on the tow line. The adhesion of the machine, therefore, is a function not only of its weight but also of the pull which it exerts. Each tractor weighs 6,450 lb., and, under test conditions with instruments and crew, 7,350 lb. Tractor No. 3 was manufactured in Paris, and equipped with one 25-h.p. mining motor. Its wheels are 11·25 in. in diameter, gear ratio is 3·4 to 1, and wheel base 42 in. The general design is the same as that of Tractor No. 1, and is shown in Fig. 2. Owing to the fact that the frame of this tractor had not been designed to receive a motor of the exact dimensions of that with which it was equipped, it was impossible to locate the motor in its proper position; it was necessary, therefore, to use 500 lb. counterweight to secure equilibrium of the machine. The weight of the tractor complete was 5,093 lb.; including counterweight, test apparatus, and crew, 6,493 lb. The mechanical construction and workmanship of Tractor 3 made it superior to Tractors Nos. 1 and 2, as was evidenced not only by inspection but also very conclusively by the results of tests. In the comparative calculations of power required respectively by the locomotive and mono-rail systems, therefore, the results obtained in using Tractor No. 3 have been used. The tractors were operated upon a mono-rail supported at a height of 4 ft. above the ground by steel posts placed at intervals of 18 ft. The rail, as used in the installation on the canal, is an ordinary 10-in. I-beam weighing 75 lb. to the yard. The mono-rail with supports and braces complete weighs 120 lb. per yard, and is erected along the canal outside the towpath. A fourth tractor, No. 4, built in Paris, was also subjected to certain tests. This machine, without

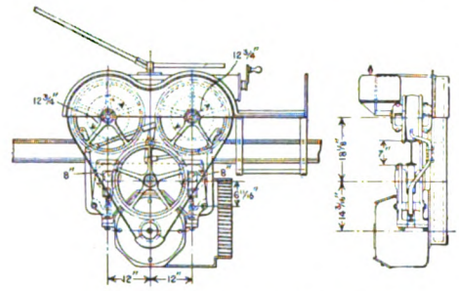

Fig. 3.—Tractor No. 4.
Equipped with one 15 H.P. Motor.

testing crew and instruments, weighed 3,465 lb. It was equipped with one direct-current 500-volt motor of 15 h.p. The diameter of wheels was 12·75 in., and the wheel base 24 in. This machine is illustrated in Fig. 3. For this smaller machine a section of mono-rail tract 1,200 ft. long was erected on wooden posts. The rail was in this case a 7-in. I-beam, weighing 45 lb. per yard, and was erected at a height of 4 ft. from the ground. In the tests the tow-line was approximately 200 ft. long. Four canal boats were loaded and used in all comparative tests made. These were 87·5 ft. long, 10·5 ft. wide, and drew 5 ft. of water. The weight of each was 24 tons empty, 138 tons loaded. The velocity of the current of water flowing in each section of the canal was determined at the time the tests were made, but to obtain an average value for towing resistance, including the effect of this current and also of track grade, all tests were made in both directions over each section of the canal. The average results are used in the calculations.

Effective tow-rope pulls required.—The effective tow-rope pulls as determined by dynamometer tests and corrected for the rope-angle for four, two, and one-boat tests, both light and loaded, are given in Table I.

Table I.

Boats.	Weight tons (2000 lb.) T.	Average speed in miles per hour. V.	Effective pull (pounds.) P.	Constant. $C = P/V^2T$.
Four boats loaded ...	548	2·98	2200	0·452
Two ,, ,, ...	274	3·62	1500	0·418
One boat ,, ...	137	4·00	1000	0·456
Four boats empty ...	95	4·00	1010	0·664
Two ,, ,, ...	47·5	4·20	560	0·668
One boat ,, ..	23·8	5·00	400	0·673

Digitized by Google

From Table I. it appears that for boats, such as are used on the Lehigh and Delaware canals, the effective tow-rope pull in pounds, required by any number of loaded boats, is expressed approximately by the formula $P = 0{\cdot}45\ V^2\ T$, and for empty boats by $P = 0{\cdot}67\ V^2\ T$, where V is the speed in miles per hour and T the total tons (2,000 lb).

It was impracticable with the facilities at hand to secure reliable data as to the effect of the ratio of boat-section to canal-section. The immersed cross-section of a loaded boat is 54 sq. ft., while the average cross-section of a canal, on those sections upon which most of the tests were made, is 440 sq. ft.; the ratio of section being practically 1 to 8. The current in the open-river section is so varied that reliable results expressing difference in pull required in the comparatively narrow sections and in these wider sections could not be obtained.

Acceleration and Maximum Rope Pulls.—Compared with electric railway operation, the rate of acceleration practicable of attainment in towing canal boats is low. Acceleration, however, is relatively unimportant, as the time of run is long compared with the time consumed in acceleration. The greatest pull is exerted when the last control point is reached, but this does not greatly exceed the pull required at full running speeds.

The following are some of the results obtained with both loaded and empty boats: Acceleration in miles per hour per second for four boats loaded (average) 0·024, (maximum) 0·045; for one boat loaded (average) 0·057, (maximum) 0·103; and for one boat empty (average) 0·109, (maximum) 0·173. Average pull in lbs. during running for four boats loaded 1,990; for one boat loaded 650; and for one boat empty, 625 (all not corrected for rope angle).

Towing Machines Tested.—In most of the tests Mining Locomotive 15 and Tractors 1 and 3 were used. Comparison was made at speeds and effective pulls as nearly identical as was found practicable. As to meet these conditions the various machines tested required different amounts of operating energy, and as change in the energy affected the motor efficiency, the electric losses in the motors in all cases have been deducted from the kilowatt input in determining the mechanical efficiency of the machines. The mechanical loss of the motors and gears in each case is charged against the respective machines. The tow-line pull in all cases has been corrected to the effective pull in pounds in the direction of motion. The mechanical efficiencies of the three towing machines tested in this way were as follows:—Mechanical efficiency for an effective pull of 1,000 lb. (*a*) Mining Locomotive, 80 per cent.; (*b*) Tractor 1, 68 per cent.; (*c*) Tractor 3, 73 per cent. For an effective pull of 3,000 lb.: (*a*) Mining Locomotive, 84 per cent.; (*b*) Tractor 1, 74·8 per cent.; (*c*) Tractor 3, 77·5 per cent. Thus the Mining Locomotive has a considerably higher efficiency than either of the Tractors at all loads.

When running without load the machines preserved approximately the same relationship as they did when operating under load conditions, though the relative magnitude of the values were changed. When developing large draw-bar pulls, the mechanical losses in Tractor 3 were 50 per cent. in excess of those of the Mining Locomotive. Mechanical losses in Tractor 1 exceeded those of the Mining Locomotive by from 70 to 80 per cent. Under light running conditions these excess losses were reduced to about 7 per cent. in the case of Tractor 3, though the excess remained approximately 70 per cent. for Tractor 1. The running light losses are, in themselves, relatively unimportant, as the amount of power required is small, and the amount of idle running relatively very small; but, as showing errors in design and workmanship, which are corroborated by the results of the heavy load tests, they are important. It is apparent that the mechanical design of these Tractor machines can be improved materially. When running light, it would be reasonable to expect that these machines, if properly designed, should effect a saving in power consumed almost proportional to their less weight as compared with the Mining Locomotive. Under load conditions, especially as the draw-bar pull approaches the maximum of which the locomotive is capable, the latter machine, theoretically, should show the higher mechanical efficiency. This is due to the fact that when the Mining Locomotive utilises its entire weight for traction; to obtain a similar draw-bar pull with the Tractor, the two driving wheels on top must have a pressure upon them equal to the weight of the Mining Locomotive. In order to assist in determining the cause of the apparently excessive friction of these Tractors, at low rope-pulls and when running light, tests were made on a wet rail to determine the relative amount of reduction in friction, and other tests were made pulling the Tractors with the gears and motor disconnected. The results of these tests show that at a speed of six miles an hour the wet rail effects a saving of about 16 per cent. in total friction, running light, and at the same speed the gear and motor friction amounted to 28 per cent. of the total.

It would seem that the mechanical efficiency of tractors of this type might be improved by giving attention to the following facts:—(1) An increase in the size of wheels would tend to decrease losses; (2) the wheel base should be long and the "flange clearance" small; (3) the mechanical construction must be such that alignment of all bearings is preserved under all conditions of operation; (4) the point of rope attachment should be carefully selected in order to reduce flange friction to a minimum; (5) the rail surface should be as good as on ordinary railway tracks, and the construction should be such as to minimise vibration; (6) the use of guides for the pressure wheels should be avoided if practicable. If used, the vertical motion in the guides for the pressure wheels should be free; (7) the pressure wheels should have no flange; (8) arrangements for oiling the bearings of tractors as well as of locomotives should follow railroad practice.

Speed Limitations.—Tests were made to determine the practicable limits of speed when towing is done with towing machines. These limits depend upon the following:—(*a*) Ability to steer the boats; (*b*) wash of canal banks; (*c*) time required for locking; (*d*) tonnage capacity and length of tow. The selection of a best speed depends also upon the number of boats which must pass through the canal in a given time to handle its business. Single boats, both loaded and empty, were tested at speeds slightly exceeding five miles an hour and no difficulty was experienced in steering them. Two-boat tows loaded were operated at speeds up to 4·5 miles an hour, but at this speed care had to be exercised by the helmsman to keep his course true. Two-boat tows (light) were operated successfully at a speed of 5·3 miles an hour. Four-boat tows (loaded) were operated at a speed of 3·5 miles an hour. At this speed, however, it was necessary for the helmsman to exercise great care to prevent the boats yawing. Four-boat tows, empty, were operated at speeds up to five miles an hour, but great difficulty was experienced in steering; the drag of the rear boat's pulling the head boats against the bank in spite of anything the helmsman could do.

The authors' conclusions in regard to limits of speed, as fixed by conditions of practicable steering, are as follows:—(*a*) Single boats, loaded or empty, can be operated satisfactorily on tangents at speeds exceeding 5 miles an hour, but on the canal for satisfactory working 5 miles an hour is probably about the limit of average speed for such tows; (*b*) Two-boat tows are handled satisfactorily at speeds of from 3·5 to 4 miles an hour; (*c*) Four-boat tows loaded can be operated with a fair degree of success at speeds up to 3 miles an hour except on very sharp convex curves; (*d*) Four-boat tows, light, were found impracticable as tested. It is possible that improved steering gear might remedy the difficulties encountered, except that no conceivable steering gear would make it possible to handle four-boat tows, light, in a heavy wind.

At the higher speeds covered by the tests a tendency to cause wash of the canal banks was noted. The tests were not of sufficient duration to justify an attempt at estimating the relation of wash and speed. At a given speed the wash is greatest in narrow sections of the canal. To a certain extent in these narrow sections the speed is automatically regulated: the resistance to the passage of the boat being increased and this resistance immediately reacting upon the series motor. The speed of towing should be under the control of the operator, and to obtain best results the motor used should be capable of operating at any desired speed within the predetermined maximum limits. With equipment of this character, the speed can be regulated on those sections where the wash might otherwise be injurious.

Time Required for Locking.—Tests were made to determine the time required in locking one, two, and four boats, and to see if the time could be reduced in any way. The authors give the following average times based on the test results:—For locking with tows of various lengths and with locks of different sizes. Times for locking with four boats: (*a*) through a one-boat lock, 45 min.; (*b*) two-boat lock, 35 min.; (*c*) four-boat lock, 20 min. With two boats: (*a*) 21 min.; (*b*) 15 min.; (*c*) 12 min. With one boat: (*a*) 8 min.; (*b*) 10 min.; (*c*) 11 min.

Energy Consumption.—The average efficiency of the mining locomotive is about 1·5 per cent. higher than that of the tractor both with alternating-current and direct-current equipment, and the average efficiency at the trolley is about 2·8 per cent. higher with direct current than with alternating current. In this case, as in the case of direct-current equipment, it is evident that the difference in efficiency of the mining locomotive and the tractor, and of alternating-current and direct-current equipment, are relatively unimportant as compared with other factors upon

Digitized by Google

which the choice of one or the other as a system of electrical haulage must depend. In Table II. are given the average results of a large number of tests made to determine the energy consumption at the trolley and the average input in kilowatts.

For the conditions existing on the Lehigh and Delaware Canals, it is estimated that the efficiency of a system of electric power transmission and conversion supplying direct current to motors will approximate 70 per cent. from bus-bars at power house to motor terminals. If alternating-current motors be used the calculated corresponding efficiency is 75 per cent. Based upon these efficiencies and the traffic conditions as existing on the Lehigh and Delaware Canals, the watt-hours required at the power house per total ton-mile and per ton-mile of freight handled are given in Table III. It should be noted that the calculated power in the above table applies only to the special conditions imposed by the physical limitations of these particular canals and by the speeds for loaded and for light boats most suitable for their operation. In all these tables the "short" ton of 2,000lb. is used.

POLYPHASE INDUCTION MOTORS FOR INDUSTRIAL PURPOSES

A PAPER dealing with this subject was read on April 14th by Mr. G. Stevenson, before the Glasgow Local Section of the Institution of Electrical Engineers. After referring to the fundamental rules which should be observed in the industrial application of electrical energy, the author emphasises the importance of the attainment of greater simplicity in the electrical part of the equipment. When installing polyphase motors there are two classes to choose from, namely: (*a*) Squirrel-cage motors, and (*b*) slip-ring motors. Naturally, the first thing to consider is the comparative cost of the two classes of motor, since, other things being equal, the choice will invariably fall on the cheaper machine. The advantage in this respect is on the side of the squirrel-cage type. If the prices of the starters are allowed for, then the squirrel-cage motor comes out still cheaper in sizes up to and including 50 h.p. Above 50 h.p. the prices of both types are practically the same. It should be mentioned that the motors here referred to are a standard line of 50-cycle 500-volt machines, which were chosen with speeds to suit their individual outputs. Thus the 5-h.p. machine is designed for a synchronous speed of 1,000; the 50-h.p. for 500, and the 100-h.p. for 500 revs. per minute, these being about the usual speeds which would be adopted in practice. With respect to the relative weights of the two types there is not much difference, the squirrel-cage machine being only about 3 per cent. lighter. The efficiencies, power factors, and overload capacities, however, are slightly higher for the squirrel-cage type. The absence of moving contacts in class (*a*) machine makes it absolutely sparkless, and therefore specially suited for operation in mines, or mills, where dangers from explosive mixtures or gases exist. Moreover, the robust construction of the rotor, due to the entire absence of coils and their attendant insulation, is a characteristic of this class of motor which appeals strongly to the mechanical engineer. It would therefore appear that class (*a*) motor should be installed in every case, but, unfortunately, it has the serious disadvantage that unless suitable precautions are taken on starting up, a somewhat excessive current is drawn from the line, and if the starting current is reduced, then the starting torque is diminished in proportion. There are several excellent methods of reducing the starting current, but nevertheless it is still the practice of some supply authorities to prohibit entirely the connection to their system of squirrel-cage machines, except in the very smallest sizes. As will be shown later, the views of the various power companies differ considerably in this respect. In order to determine the current taken from the line at starting in terms of the full-load current, and the resulting torque, the author tested some machines built for operation on a 500-volt, 50-cycle three-phase circuit. These tests showed that squirrel-cage motors, if switched straight on to the line, take from 4·55 to 6 times their full-load currents. The adoption of this method of starting is, therefore, out of the question, except in the very smallest sizes, say up to 10 b.h.p., on account of the violent disturbances which would result to the supply pressure. Moreover, the power factor under these conditions is of the order of 0·4, and this causes excessive idle or "wattless" currents in the line, thus affecting objectionably the pressure regulation of the system. The starting torque for a motor rated at 35 h.p. will be about 1·13 times the full-load torque, and this with a starting current equal to 4·55 times full-load current. These figures may be taken as being fairly representative of good modern machines, although by a special design of rotor it is possible to improve very considerably the results given above. In order to overcome the defects of squirrel-cage motors, methods must be employed which will permit of:—(1) A reasonable starting current being drawn from the line; (2) such arrangements in the disposition of the motor in relation to its work as will enable it to start under comparatively light load conditions, say, not exceeding half full-load torque; or (3) the adoption of a special form of "high torque" rotor.

Stator Starters.—One method of starting induction motors, when the operating conditions of the driven machinery permit, is to keep all the motors coupled up to the line and start them simultaneously with the engine and generator. This method, however, cannot be used except where the installation includes the generating plant. The current taken at starting is very small with this arrangement, but it would appear to be necessary to have separately driven exciters, in order that the main generator may be started from rest with full voltage on the field. Facilities for starting any individual motor would also have to be provided, since it would obviously not be feasible to shut down the whole plant and start afresh in the event of one motor being put out of action. The only example which the author has heard of is that of a cotton mill in Georgia, United States.

Viewed from the standpoint of simplicity, perhaps the next best method of starting class (*a*) machines is that patented by H. S. Meyer. The method adopted in the case of two-phase motors is to connect the stator windings in series at starting, so that the voltage per phase is only half of the line voltage, and the starting current and torque are reduced to one-quarter the value they would have if full voltage were impressed at the

Digitized by Google

motor terminals. After the machine has run up to speed, the switch is thrown over to the running position, when each phase receives its full pressure. In the case of three-phase motors they are designed for running normally on delta connection, the starting being effected by switching on to the line with the windings connected in Y grouping. By this means the voltage per phase at starting is only 58 per cent. of the line voltage. The starting current and torque are, of course, also reduced; for instance, taking the 33-h.p. machine to which reference has already been made, the starting current would be only one-third of that taken if motor were switched straight on, or 1·5 times full-load current. The starting torque being proportional to the square of the voltage would be reduced to one-third of its value at full load. The author has used these methods for two- and three-phase machines up to 50 h.p. with excellent results. The switch used is of the air-break type for motors up to 20 h.p. on a 500-volt circuit. Above this size it is good practice to use an oil-break switch. Power users are at last beginning to realise the effect of shafting and other frictional losses on their bills for current, with the result that, in new equipments at all events, high-class roller bearings are taking the place of the old solid pattern. The saving in power effected by the adoption of roller bearings is stated by the makers to be from 10 to 25 per cent., and they claim that the extra initial cost will be returned in the first year's operation by the saving in power alone. Returning to the subject under consideration, mention may now be made of what is probably the commonest method of starting squirrel-cage machines, namely, the use of the so-called compensator or auto-starter. The arrangement is equivalent in effect to a step-down transformer. When the switch is placed in the starting position, the voltage across the motor terminals is only a fraction of the line voltage. After the motor has reached normal speed, the switch is thrown into the "Running" position, and the motor is then supplied at the full-line voltage. Each phase of such a compensator is provided with several taps, so that a number of sub-voltages may be obtained, any one of which may be selected for permanent connection to the switch for starting the motor, according to individual requirements. The three coils of the three-phase winding are connected in "Y," the line to the three free ends of the coils, and the starting connections of the motor to the taps. To meet various requirements, compensators for standard motors of 5, 10, and 15 h.p. are usually provided with taps for starting the motor at 40, 60, and 80 per cent. of the line voltage, with respective line currents equal to 16, 36, and 65 per cent. of the current that would be taken by the motor if no compensator were used. For larger motors compensator taps should be provided giving potentials equal to 40, 58, 70, and 85 per cent. of the line voltage, and respective currents equal to 16, 34, 50, and 72 per cent. of the current that would be taken by the motor if it were started direct from the line. The proper tap for giving maximum starting effort without causing an objectionable voltage variation in the supply circuit may readily be ascertained by trial, and permanently connected, at the time of installation. A defect of the ordinary pattern of compensator is that the motor may be switched straight on to the line, thus causing a rush of current, which it is the object of the compensator to avoid. The switch can be, however, provided with a latch, so arranged that the lever at "Off" can be thrown only into the starting position, and can be thrown from thence into the running position only by a quick throw of the lever. A number of motors may be started from one auto-transformer, thus saving the expense of installing individual compensators. A throw-over switch is provided for each motor to be started, and a three-pole compensator magnetising switch. Only one motor would be started at a time, and when all the motors are started the compensator magnetising switch would be opened. The chief objection to the compensator as a starting device is its excessive cost, this being usually about one-third the cost of the motor. Furthermore, it has been found that under actual working conditions cases frequently occur of coils being burned out, due to the switch being left in the "Starting" position. Some makers use a resistance in the stator circuit for starting up, but the method is not advisable, since the current is only reduced in proportion to the reduction in the voltage, while the torque is reduced as the square of the voltage. The foregoing covers the principal devices in use at the present time for starting-up class (*a*) motors. Numerous attempts have been made to increase the starting torque of this class of motor, while preserving its characteristic features of simplicity and robust construction. Among the more interesting may be mentioned:—(1) Boucherot's* three methods—use of component rotors, movable stator, and phase transformer; (2) Hobart* (utilisation of skin effect); (3) Zani* (use of inductance coils). More recently Hunt† has devised a cascade arrangement.

* Hobart's *Electric Motors*, pp. 266—291.
† *Journal, Institution of Electrical Engineers*, vol. xxxix, p. 648, 1907.

Clutch Starting.—None of the above methods, however, with the possible exception of the last-named, appear to have attained to any degree of commercial importance, in this country at least; and, in the author's view, the problem ought to be approached from the opposite standpoint—that is to say, that, instead of designing the motor to suit the conditions, arrangements should be made to permit the installation of the ordinary simple squirrel-cage machine. As an example of what is meant, the case of a mortar-mill drive may be mentioned, a class of drive which, as most engineers know, is somewhat troublesome, both in regard to the starting and overload conditions. The machine was situated in a very dusty position in a foundry, and, after taking all the circumstances into consideration, it was decided to adopt a friction clutch in combination with suitable single reduction spur-gear, and a class (*a*) motor with star-delta starter. A word or two is necessary in regard to the clutch, which is of the "coil" type. The shaft, which is driven by the motor, has keyed upon it a cylindrical drum, which is hardened and ground. Coiled round this cylinder is a steel coil attached to a casting, which either carries a gear-wheel or belt pulley, or if the clutch is used as a coupling it is keyed on to a separate shaft. When it is desired to put the clutch in gear, a loose collar is moved towards the coil by means of a lever, operated either by hand or screw; this in turn actuates a hooked lever, which presses on the tail of the coil, causing it to wind gradually and tightly round the cylindrical drum. The advantages of this clutch are that it is easily made for all powers, even up to 2,000 h.p., and by operating the starting lever by means of a wheel and screw there is not the slightest shock when it is put into gear.

Reference has already been made to the advantages of the squirrel-cage motor for mining work. Difficulties in the way of its application to the various power requirements of a coal-mine can generally be overcome by suitable mechanical arrangements. Take, for example, the case of haulages. The three systems in general use—that is, direct haulage, main and tail haulage, and endless-rope haulage—can all be operated quite satisfactorily by means of squirrel-cage machines in combination with suitable clutches. Of these three systems the last-named is the easiest to operate in this way, because it is not necessary to start and stop at frequent intervals. The speed of the motor can also be kept constant, since the gear is usually designed for a uniform rope speed of about two miles per hour. The best position for the clutch is direct on the haulage drum, because the motor can then be quickly relieved of its load should the tubs chance to come off the road. Practical mining engineers are agreed that clutches give a control over the haulage which is unattainable by other means. The various types of pumps in use for mining purposes can also be readily arranged for driving by this class of motor. In the case of three-throw pumps, a by-pass valve can be fitted, thus enabling the motor to start up light. With respect to centrifugal pumps, which are now coming so rapidly to the front for high-lift duty, it is quite a simple matter to make provision for starting the motor under light load. All that is necessary is to insert a sluice valve in the rising main near to the discharge side of the pump. By closing this valve, starting may be effected with about one-quarter to one-third of full-load torque. The author has used this method with motors of the squirrel-cage type up to 100 h.p. As regards coal cutting machinery, this class of work is probably the most difficult to tackle by any type of motor, not merely on account of the requirements at starting, but also because of the excessive vibration and overloads, and rough usage generally, to which such machines are subject. The squirrel-cage motor is peculiarly suited for these conditions, and is now largely used for driving the various types of coal-cutter. As regards the starting arrangements, some makers rely on the ordinary compensator only, while others adopt a suitable device to enable the motor to start up light. In the application of class (*a*) motors to the driving of textile plant, the motors are connected direct to the ring spinning frames by means of clutch couplings, and handles operating the clutches are placed in convenient positions for the attendant.

Slip-ring Motors.—In some cases, however, it is found that the ordinary form of low resistance rotor does not meet the requirements. The starting torque of an induction motor is increased by an increase in the resistance of the rotor windings. Hence by making the rotor bars of higher resistance, the specific starting torque may be increased. To take, for example, the 33-h.p. motor, to which reference has already been made, by making the rotor with 66 per cent. higher resistance, the starting current would be reduced by 3 per cent., and the starting torque would be increased to 1·75 times full-load torque. The increase in the resistance of the rotor naturally means a lower efficiency, but the difference is such as in many cases to be well worth the advantage gained in respect to the starting qualities of the machine. In the case under discussion, the efficiency would be reduced by 2 per cent. The power factor would be slightly increased, so

Digitized by Google

that the reduction in the apparent efficiency—which is the really important point—would be slightly less than 2 per cent. This leads to a consideration of class (*b*) motor. The rotor coils are usually Y connected, and their terminals taken through a hollow shaft to collector rings on which rest carbon brushes supported by the usual spring holders. By means of a rheostat external to the motor suitable resistances can be inserted in each phase at starting. The starting torque with this type of motor can be anything up to about twice the full load value, but in special cases up to three times. The starting current corresponds to about full-load current when starting with full-load torque, and proportionally more when starting with greater torque. In those cases in which no speed regulation is required, provision is usually made to short-circuit the winding in itself, instead of through the brushes and rheostat leads, so soon as the motor has reached normal speed. In some cases a brush-lifting device is also provided with the object of reducing the wear and tear on brushes and rings. In the author's view, however, the latter refinement is unnecessary for most ordinary purposes, and usually gives more trouble than it is worth. It will be seen from the foregoing considerations that the adoption of the squirrel-cage type of motor, whenever the conditions permit, would be entirely in accordance with the dictates of good engineering. Of course there are certain cases where it is not feasible to adopt this type, notably for crane work, although even here the author has seen successful examples of crane driving by means of squirrel-cage machines. When all is said and done, however, the choice of type, except in private plants, is subject to the approval of the supply authority. It therefore becomes necessary to ascertain to what extent the consumer is enabled to take advantage of the superior qualities of class (*a*) motor. Accordingly the author obtained the rules of the principal companies and corporations supplying polyphase current in the United Kingdom with respect to this point. One would naturally expect that the maximum size of class (*a*) motor allowed would be dependent in large measure on the station plant capacity, because in a private plant the total capacity of squirrel-cage motors, and the individual capacity of any one squirrel-cage motor, should bear a relation to the generating plant such that each squirrel-cage machine can be stopped or started at any time during normal working without interfering with the running of the other motors on circuit.

It is interesting to notice, however, that this consideration does not seem to have much influence on the restrictions imposed, for one company with a station plant capacity of 6,000 kw. allows a class (*a*) motor of 100 b.h.p. against 50 b.h.p. in the case of another company, with a plant capacity of 20,000 kw. A third company with a plant capacity of only 1,000 kw. allows a motor of 20 b.h.p. Two local authorities do not allow class (*a*) motors over 5 h.p., and it is often specified that motors must start on a loose pulley. The maximum permissible starting current is generally given as one and a quarter times full-load current. As a matter of fact, however, the author has found that the rules of the various power companies need not be too rigidly interpreted. The power companies are more favourably disposed towards the adoption of class (*a*) motors than are the various local authorities. Moreover, the author ventures to affirm that local authorities are in a great many cases overburdened with rules and regulations, which must inevitably hinder the development of power supply. The question is of importance at the present juncture, in view of the inquiry held by the Home Office to deal with the rules and regulations concerning the application of electrical energy in factories. The power companies seem to be able to get along comfortably with a set of rules embraced by a single sheet of foolscap. The local authority, on the other hand, appears to require protection to the extent of a bound volume of 30 or 40 pages. Among anomalies in the way of rules which the author has encountered, reference will be made to two only:—(1) The power factor of any motor *must not fall below* 0·8. (2) Before any application for power *can be accepted*, the name of the maker of the motor must be stated. (The italics are the author's.) The power factor is, however, a function of the load. Rule (1) as it stands is equivalent therefore to the demand that the motor shall always be operated at a given output, which of course is absurd. With respect to rule (2), it is surely not within the province of the supply authority to interfere in this connection, and in any case the author fails to see that the rule serves a useful purpose.

Before leaving the subject of power factor the author would like to emphasise the importance of choosing a motor which shall not be too large for its work, because the power factor falls off very rapidly with reduction in load. One of the points, therefore, to which attention should be given is to endeavour to operate each motor at its rated output. In fact, no harm is done to a high-class machine by an occasional overload. The overall power factor for an installation depends on the amount of attention which is given to the foregoing considerations. In actual practice it is customary to assume a figure of 0·8 for general industrial plants and 0·75 for mining installations, although this must of necessity be a variable figure, dependent entirely on local conditions. The author's experience tends to show that it takes a load of a very steady nature, together with a very well laid-out plant, to attain a figure of 0·80 in actual everyday operation. This is probably only attained under the most favourable circumstances in a textile or similar plant.

In conclusion, the author ventures to affirm that electrical engineers in general are too apt to attempt a solution of each and every problem by electrical means, and without sufficient consideration of the case in its mechanical aspects. As proof that his own practice is in accordance with his precepts, he would mention the case of a large foundry and engineering works for the electrical equipment of which he was responsible. Out of a total of some 40 motors, aggregating about 500 h.p., only four, or 10 per cent. of the total, were of the slip-ring type, the others being adapted to the various requirements by the mechanical arrangements outlined in the paper.

POWER TRANSMISSION BY HIGH-TENSION CABLES

In a Paper read before the Elektrotechnischer Verein, Berlin, on February 11th last, Richard Apt (of the Allgemeine Elektricitäts Gesellschaft) gave a *résumé* of the present state of our knowledge with regard to high-tension cables, and discussed the question as to whether power transmission by insulated cables at high pressures and over long distances were possible. The following is an abstract of the Paper and discussion, from the full report in the *Elektrotechnische Zeitschrift*.

Until now, the three-phase system has been almost exclusively employed for power transmission, partly because there was no single-phase motor which could compare with the three-phase motor as regards efficiency and suitability for heavy work, and also partly because, for a given amount of power transmitted, the three-phase system requires the least amount of copper in the transmission line. In consequence of this, the usual type of high-tension cable now manufactured is the three-phase three-core type.

One disadvantage of the three-core type of cable is that at high pressures the section of core is very limited, as the overall diameter of the cable, on account of the large amount of insulation required, easily reaches the value of 3½ in., at which size the author considers the limit of weight and flexibility is reached. From this consideration the author comes to the conclusion that it will not be advisable to make use of three-core cables at working pressures above 20,000 to 30,000 volts, but that three single-core cables will, in such cases, give a more satisfactory result.

The author then proceeds to give a summary of the theory of single-core insulated cables. Starting from O'Gorman's theory of the potential gradient, he shows how, for a given maximum stress in the dielectric, the thickness of the dielectric depends not only on the working pressure, but also on the radius of curvature of the copper core. As a consequence, there is, for any given pressure, a section of core for which the total cost of the cable will be a minimum. Several methods have been proposed for obtaining a uniform stress in the dielectric surrounding the conductor; that known as grading the insulation, proposed and patented by O'Gorman (see Electrical Engineering, January 9th, 1908, page 37) is the only one which has been used in practice.

In the case of single-core cables there are, besides the copper losses, auxiliary losses due to eddy-currents in the lead sheaths. The author gives a short summary of the investigations made by M. B. Field in order to determine the value of these losses, and points out that, in cases of long transmission lines with a low periodicity, these losses would be negligible in comparison with the copper losses. Besides the copper losses and the above-mentioned eddy-current losses, there are the losses due to hysteresis in the dielectric. So long as the dielectric is not overstrained, these losses are proportional to the square of the pressure and to the first powers of the capacity of the cable and the periodicity. These losses can be calculated, and are in general not large enough to affect seriously the economy of the system. An important loss, however, is that due to the no-load

Digitized by Google

capacity current, which at high pressures becomes very considerable.

Although the large power transmission schemes have been almost exclusively carried out on the three-phase system, there are a few cases of power-transmission in Switzerland and France on the Thury high-tension direct-current series system. The simple transmission line required for the latter system, and

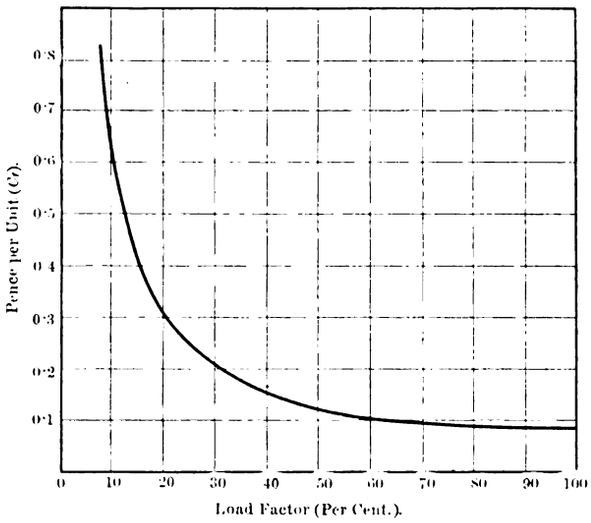

Fig. 1.—Cost of Transmission by Cables at Various Load-Factors.
(70,000 Kw. at 40,000 Volts over 87 Miles.)

the total absence of disturbances and limitations due to inductance and capacity, compensate largely for the higher cost and complication of the generating plant and sub-stations. Other disadvantages which must be remembered are the difficulty of enlarging an existing installation and the necessity for automatic regulation. However, considering that the effects of capacity and inductance are the chief factors limiting the practicable distance of transmission by alternating currents, the direct-current series system may come more to the front in the future for very long distance transmission. Again, for a given working pressure, the maximum stress in the dielectric is less for direct-current than for alternating current; and consequently the insulation in the former case need not be so thick as in the latter.

The possibility of the electrification of the main-line railways on the single-phase system, introduces this system as a desirable method of transmission. Although a three-phase transmission line requires only 75 per cent. of the amount of copper necessary for a single-phase line, the saving in copper is, under certain conditions, quite offset by the extra expenditure on the insulation and lead when high-tension cables are considered, particularly if sets of three single-core cables are to be used instead of three-core cables. Taking as an example the case of the transmission of 10,000 kw. over a distance of 62 miles at a pressure of 30,000 volts between conductors, and assuming a power factor of 0·85, and a total drop in pressure of 10 per cent., a section of 0·71 square inch per conductor would be required for the single-phase system, and a section of 0·355 square inch per conductor for the three-phase system. On account of the high working pressure, single-core cables would be used in each case. If the middle and neutral points respectively of the two systems are earthed, the pressure between core and lead covering is for the single-phase system 15,000 volts, and for the three-phase system 17,300 volts. Comparing the total costs for the two systems, inclusive of the cables, the materials for the underground construction and the cost of installing the same, the single-phase system works out 8 per cent. cheaper than the three-phase system in the case considered.

In order to show that a long transmission by means of high-tension insulated cables is within the limits of practicability, the author gives the following example:—A three-phase line for the transmission of 70,000 kw. over a distance of 87 miles at a pressure of 40,000 volts between conductors. If the system is star-connected, and the neutral point earthed, the pressure between the core and the lead covering in each of the single-core cables is 23,000 volts. For a total drop in pressure of 13 per cent., the necessary cross-section per conductor is 1·8 square inch. This is too large a section for one cable, so three sets of three cables should be used, each cable having a copper section of 0·6 square inch. The total number of cables, including one as a reserve, is thus ten. The cost of the whole 87 miles of cable and underground construction can be taken as approximately £1,200,000 or £13,800 per mile.

The cost of energy per unit at the generating station can be denoted by C_g, and this can be expressed as the sum of the fuel costs and the other generating costs per unit. The fuel costs are practically proportional to the load on the generating station, and therefore the fuel costs per unit (C_f) will be fairly constant, whatever the load-factor. The other generating costs (interest on capital cost of station, wages, maintenance, &c.) are nearly constant, and consequently these costs per unit (C_s) will vary inversely as the load. Denoting the value of the load-factor by p, the following equation expresses the relation between these quantities:—

$$C_g = C_f + \frac{C_s}{p}.$$

For the purposes of the present investigation, the fuel cost per unit (C_f) can be taken as 0·156d., and the other costs (C_s) as 0·036d. per unit. By substituting these values in the equation above, the total generating cost per unit can be readily obtained for any particular value of the load-factor p.

The cost per unit at the receiving end of the line is equal to the cost per unit at the generating end, divided by the average efficiency of the line. The cost of the units lost in transmission is thus divided over the number of units delivered, and paid for by the consumers. To this value of the cost per unit must also be added the indirect costs of transmission, which consist of the interest on the capital cost, maintenance, &c., of the transmission line. These last will be inversely proportional to the load factor p. Denoting this cost by C_l and the average efficiency of the line by η, then the cost per unit at the receiving end of the line (C) is expressed as follows:—

$$C = \frac{C_g}{\eta} + \frac{C_l}{p}.$$

If the interest on the capital cost is taken as 4·5 per cent., the sinking fund at 3 per cent. and maintenance and depreciation at 1 per cent., then the total annual expenditure on the line alone is 8·5 per cent. of the capital cost of £1,200,000, or £102,000. Dividing this by the number of kilowatt hours delivered at unity load-factor in one year, the value of C_l is obtained, thus:—

$$C_l = \frac{102{,}000 \times 20 \times 12}{365 \times 24 \times 70{,}000} = 0{\cdot}04\text{d.}$$

The average efficiency of the line must be calculated for each value of the load-factor, and all the line losses must be included. The following table shows how the cost per unit at the generating and receiving ends of the line is affected by the value of the load-factor. The last column gives the cost per unit of transmission (C_t) which is the numerical difference between C and C_g.

These values are plotted as a function of the load-factor in Fig. 1. From this curve it can be seen that the cost of transmission is less than one-tenth of a penny per unit with high values of the load-factor.

Dr. Apt includes in his Paper a description of that portion of the high-tension cable line of the County of Durham Electrical Power Distribution Company, Ltd., which was laid by the Allgemeine Elektricitäts-Gesellschaft. The line consists of over 60 miles of 20,000 volt cable. These cables, which are of the ordinary three-core lead-covered type, were supplied in two sizes, 0·05 and 0·10 square inch sections per core respectively. The stranded cores are sector shaped, and are insulated with paper, a further thickness of insulation round all three cores being provided.

Each length of cable was tested at the works for 24 hours at 30,000 volts and 15 minutes at 50,000 volts. Test pieces, which were coiled to a diameter of twelve times the diameter of the cable, were required to withstand a pressure of 80,000 volts for two minutes. The cables were laid in earthenware troughs, which were filled in with asphalt mixture, as is shown in Fig. 2. After laying, the whole length of cable was put under a test pressure of 40,000 volts between the cores and the lead covering for half an hour. A telephone cable and a cable containing the pilot wires are laid in the ground directly under the trough containing the main cable.

The current is supplied from the power station at Carville at a pressure of 6,000 volts, to the two chief sub-stations at Gateshead and Yarrow, where it is transformed up to the pressure of 20,000 volts for the high-tension network. Some of the single lengths of cable are over 7·5 miles long, and the capacity current at 40,000 volts and 40 ~ is about 5 amperes per mile. The testing at this high pressure was carried out with the aid of a choking-coil as follows:—The choking-coil was connected across the high-tension winding of the testing transformer, as is shown in Fig. 3. The leading current taken by the cable was thus compensated for by the lagging current taken by the choking-coil, and consequently the transformer had to supply the losses only. The whole cable network has been in operation for about a year, and has given entire satisfaction.

In conclusion, Dr. Apt states that he does not agree with the results obtained by Mr. R. D. Mershon in an investigation in which he came to the conclusion that the longest practicable distance for electrical transmission was about 500 miles. In Dr. Apt's opinion, no general limit could be fixed.

In the discussion to the above Paper, at Berlin, Mr. Schrottke thought that the very high capital cost of an underground transmission line, in comparison with that of an overhead line, would generally lead to the adoption of the latter. He had calculated the cost of an overhead line, corresponding to the underground line taken as an example by Mr. Apt, and estimated the cost of the line alone to be some £400,000, or one-third of the cost of the underground line. He had, however, estimated for a single 66,000-volt steel tower transmission line, with towers 70 ft. high, spaced 650 ft. apart. Each tower would support 12 copper conductors (four three-phase circuits), each conductor having a cross-section of 0·155 sq. in. The working costs work out at less than half the corresponding costs for the underground line. As regards the dangers of breakdown, Mr. Schrottke pointed out that the conductors swing synchronously in the wind, and would not come in contact. He also thought that the danger of damage by lightning had been exaggerated. The capacity current was a very serious drawback to a cable line. He had calculated the capacity current for the 140 km. example given, and estimated that each set of three cables would require a 10,000 K.V.A. generator to charge them up to the potential of the line at 25 ~. Compensation by means of choking coils would, he thought, be too expensive. The capacity current of a corresponding overhead line would be not more than one-twentieth of the above amount.

Dr. Apt in reply agreed that where possible an overhead line would be constructed in preference to an underground line, in consequence of the high cost of the latter. To emphasise the reality of the danger of breakdown due to lightning, he mentioned the case of a large mining company in South Africa which constructed an underground line for transmission from their central station to the mine, in spite of the higher capital cost. The generating station which supplied the town of Johannesburg over an overhead line, experienced frequent breakdowns due to the line being struck by lightning, in spite of the fact that protective devices were provided.

The discussion was continued by Mr. Lichtenstein, who did not agree with Dr. Apt that three-core cables should be replaced by single-core cables for pressures over 30,000 volts. As a result of some experiments which he had made in the laboratory of the Siemens-Schuckertwerke, he was convinced that satisfactory three-core cables could be constructed for pressures of 30,000 to 40,000 volts, having a normal section of conductor, and a permissible value of the overall diameter. He thought that the three-core cable had considerable advantages over the set of three single-core cables, even at these high pressures.

The American Bell Telephone System.—The annual report of the American Telephone and Telegraph Co., still known commonly as the "American Bell," states that at the close of last year there were 3,839,000 stations connected, with a total of 8,610,592 miles of wire. There were 5,997,000 exchange and toll calls during the year. During the year $52,921,400 was spent on construction, and 768,340 stations were added. The total number of exchanges and branch offices is 5,108, representing an increase of 219 for the year. A total of 88,274 employees are in the service of the company. In addition to the expenditure on new construction already mentioned, $36,626,667 was spent out of revenue on maintenance and re-construction. Arrangements have been made with the Western Electric Co. by which this manufacturing company is now free to supply telephonic apparatus to any purchasers, instead of being bound as hitherto to sell in America only to the Bell group of companies.

Compressed Cotton Brake Blocks.—In the course of a general review of the working of the London Underground Electric Railways in the *Railway Gazette*, attention is called to the recent substitution on these lines of brake blocks of a special form of compressed cotton instead of metal. A good deal of trouble has been experienced with metal blocks, owing to the accumulation of large quantities of pulverised steel on the track and conductor rail insulators. To obviate this, brake blocks of cotton fibre have been adopted on the new London tubes, where they have been completely successful, though when used in the open parts of the District line defects have been observed which are now being investigated. The blocks consist of five layers of heavy woven cotton impregnated with resin and asphalte. Their coefficient of friction is considerably higher than that of cast steel blocks, and in use it is necessary to train the motormen to make a somewhat lighter application than with the metallic blocks in order to avoid sticking and skidding, but when the train line pressure is reduced by 10 lb. satisfactory results are obtained. Trouble was at first experienced by the flowing of the sheets outwardly away from the wheel flanges so that, occasionally, parts fell on the permanent way, and, owing to the impregnation, clung to the rail where they usually dropped, giving rise to false reports of broken rails. Cotton fibre has no grinding effect on the wheel tyre, but it has the slightly bad effect that it does not keep the wheels trued, and inexperienced motormen are liable to produce a series of small flat spots due to short-time skidding. The blocks having no cutting action, the tyres remain somewhat rough to an extent that can be detected in rough riding. This is a small defect inasmuch as it can be easily obviated by training the men. On the other hand, the absence of grinding action has a highly beneficial result in the saving of tyre wear, and the consequences of it to which we have already referred. The average life of the cotton composition brake block in the tubes is found to be on trailers about 20,000 miles, as against 13,000 miles with metallic blocks. The cotton fibre blocks have not so far been successful on the open parts of the Metropolitan District line, as shown by experiments made on their South Harrow branch, probably owing to damp. These become "clammy" in the language of the men in charge, and there appears to be difficulty in releasing the brake, showing a want of uniform adhesion and some erratic actions. The brake blocks have the appearance of having absorbed some moisture, although it should be possible to overcome this fault.

AN ELECTRIC CAR TESTING PLANT

An elaborate electric car testing plant, which forms part of the equipment of the electric railway engineering laboratory at the Worcester Polytechnic Institute, in America, is described in the *Street Railway Journal*. The apparatus, which was designed by Prof. A. S. Richey, is connected to the lines of the Worcester Consolidated Street Railway Co., and is modelled upon the locomotive testing plants at Lafayette, owned by Purdue University, and at Altoona, owned by the Pennsylvania Railroad Co. The general scheme is that of holding the car under test over a set of supporting wheels which correspond to the track. These supporting wheels bear the weight of the car and turn with the car wheels, the car body being coupled to a rigid end post. Wind resistance, linear inertia, &c., are provided in an effective manner by means of flywheels and electric brakes, as will be described.

Four sets of stands are provided, each one carrying a pair of bearings and a supporting shaft. These four stands rest on and are bolted to parallel heavy I-beams which are embedded in the concrete foundation. Each of the shafts carries a pair of steel-tyred supporting wheels. The bearing surfaces of the supporting wheels are turned to the same section as the head of a 100-lb. rail, and each pair of wheels is spaced on the shaft just track gauge distance apart. The stands, with shafts and supporting wheels, may be shifted on the foundation I-beams to provide for cars of various truck and wheel base, a final fine adjustment being provided by a movement of the bearing pedestals on the stands by shifting screws. Thus far the arrangement is patterned directly after the locomotive testing plants which have been mentioned. The arrangements for imitation of inertia, wind resistance, &c., are entirely different, however.

No arrangement has been used with the locomotive testing plants for the imitation of inertia, as it would be exceedingly difficult to imitate safely the inertia of the entire mass of the moving train for the movement of which the locomotive is designed. As the motors on a single electric car, however, are generally designed to handle but the one car, flywheels may be designed which will correctly imitate such inertia, and this has been done in the present case. Each of the supporting shafts carries a flywheel. These flywheels are made up of boiler plate in order to provide strength against the high values of centrifugal force at high speeds, and also in order to provide an easy method of changing flywheel weights to suit cars of different weights. Individual interchangeable boiler plate discs, varying in thickness from ¼ in. to ¾ in., are provided. By making up flywheels of different thicknesses, it is possible to imitate correctly the linear inertia of single-truck cars weighing 8, 10, 12, or 15 tons, or double-truck cars weighing 15, 20, 25, 30, 35, or 40 tons. The flywheels enable breaking tests to be made, as well as motor tests.

The form of friction brake which has been used in connection with locomotive testing plants has here been replaced by electric brakes, consisting of standard G. E. 57 motors mounted on and geared to the shafts between the supporting wheels. These motors act as generators, the fields of all four being in series and separately excited. Their armatures, however, are connected in parallel to a resistance load. While this resistance load is variable, it is only varied to care for extreme changes which may be desired, as a better regulation is obtained, within limits, by varying the field of the exciting generator, this varying in turn the fields of the brake generators and their voltage. It may easily be seen that power to overcome wind resistance and resistance due to track grades may be taken up by the braking effect of these generators, at the same time being entirely separate from the power used to overcome inertia, which is correctly stored in the flywheels as kinetic energy as momentum is acquired, to be dissipated in friction as the car slows down either through drifting or braking. At the same time, the entire tractive effort is shown by the pull on the drawbar of the car under test.

The arrangement of brake generators above described performs another important function, that of keeping all supporting shafts rotating at similar speeds at all times. The electric car is not commonly provided with connecting rods between drivers, consequently some corresponding device must be used between the supporting wheels, else the various car wheels would be running at various speeds on test; especially would this be true while the car motors were in a series connection. The series connection of brake generator fields, separately excited, and the parallel connection of brake generator armatures, whether on or off the resistance load, solved the problem quite satisfactorily. Various schemes for bevel gear, connecting rod, belting or rope drive connection between the supporting axles were proposed and discarded, chiefly because of difficulties in shifting stands to accommodate various wheel bases.

For shifting cars on and off the test stand, channel iron supports for special rails are temporarily bolted to the inside of the supporting wheels and to the ends of the track rails at the door of the laboratory. These channels are supported by wedges which fit the hubs of the supporting wheels, and are also blocked up between stands for additional strength. These channels support special rails which carry the car on its flanges until the car wheels are over the supporting wheels, where the tread of the car wheel rests on top of the supporting wheel, the stands having been correctly spaced for the wheel base of the car and the height and position of the special rail having been adjusted to suit the flange section of the car wheel previously. Arriving at the proper position, the car is held rigidly in place by a coupling to an end post. The channel irons are then unbolted from the supporting wheels, and the supporting wedges removed, allowing the full weight of the car to be borne by the supporting wheels. An arrangement is provided for supporting the channels independently and clear of the supporting wheels while a test is in progress, a quick shift bringing them back into position for carrying the car off the stand upon the completion of a test. The drawbar and post arrangement for holding the car in position will be replaced, eventually, by a traction dynamometer for measuring the tractive effort of the car under test.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

A process for the recovery of nickel from oxide and silicate ores is described by William Koehler in *Electrochemical and Metallurgical Industry* of April. The usual smelting and refining processes employed for the winning of nickel are not readily applicable to the garnierites, which contain nickel-magnesium silicates, oxides, &c. This class of ores is largely found in New Caledonia, North Carolina, and Oregon. Sepiolite or meerschaum is a mineral which usually has the formula $H_4Mg_2Si_3O_{10}$, but the magnesium is often replaced by copper or nickel. For example, an analysis of an ore from North Carolina showed it to contain 17·84 per cent. of nickel. The method employed to obtain the nickel from such an ore is briefly one of chlorination, roasting to decompose the more unstable chlorides, leaching and electrolysis to recover the nickel.

The metallic chlorides are by no means equally stable, some being very readily split up when roasted in a current of steam. For example, it is not possible to obtain anhydrous aluminium, iron, or magnesium chlorides by evaporating the solutions to dryness, because they are hydrolytically decomposed with formation of the oxides, $2AlCl_3+3H_2O=Al_2O_3+6HCl$. On the other hand, a solution of nickel chloride may be evaporated down without decomposition. It follows, therefore, that if we are dealing with a mixture of nickel chloride and iron chloride, on heating such a mixture with steam, and by a careful regulation of the temperature, only the iron chloride would be decomposed, with formation of ferric oxide. On leaching out this product a solution of nickel chloride, containing practically no iron, would be obtained.

The chlorination may be carried out in a variety of ways, such as heating the ore in a rotary kiln and passing over chlorine gas, or by the action of ferric chloride, but Koehler prefers to heat it with hydrochloric acid, as by this method no foreign material is added, and it is easier to manipulate than roasting in presence of chlorine gas. After chloridisation, the product is placed in a rotary kiln and heated to a temperature which must be below the decomposition point of the chloride of the metal to be recovered, steam and air at the same time being passed over it. The hydrochloric acid from the decomposable chlorides is thus recovered, and can be again used.

After this treatment the mixture is leached out with water,

Digitized by Google

when a solution of nickel chloride is obtained. This solution is then electrolysed, using insoluble anodes of carbon, the nickel is deposited out at the cathode, and chlorine obtained at the anode. The process has been carefully tested at one of the leading electrolytic copper refineries in the United States, and they report it to be metallurgically sound, and advise the erection of a plant to work it commercially. En passant, it is mentioned in the article that the Brunner Mond Alkali Co. produced from November, 1905, to October, 1906, 2,595,382 lb. of zinc and 8,360,660 lb. of bleach by the electrolysis of zinc chloride by the Hoepfner process. It should also be mentioned that the electrolysis of nickel chloride upon a commercial scale is not new. The International Nickel Co., for example, are producing nickel by this method. In the same number of *Electrochemical and Metallurgical Industry, loc. cit.*, J. R. Crocker contributes an article upon Diaphragms. It is written mainly from an historical and suggestive point of view; suggestive because the author remarks in the first paragraph, "extended and expensive experiments have been made to find the ideal conditions, or the ideal material, but the field is still open for improvements, and many diaphragms at present in use are in somewhat of an experimental state." Porous plates of earthenware are first described, these unfortunately are imperfectly permeable; therefore it has been attempted to locate liquids between two separate partitions. This works all right, provided the liquid diaphragm can be kept in a definite and steady position, but owing to chemical action, mechanical shocks, &c., this is in practice an extremely difficult matter.

As to diaphragm materials, these are exceedingly varied. Asbestos in one form or another is very largely employed, but even with this material there are very considerable practical difficulties. If natural asbestos is employed in an alkaline solution, it soon becomes non-conducting; this is probably due to precipitation throughout the material of non-conducting material; this stops up the pores, and consequently electrolytic conduction can no longer take place. The asbestos is therefore frequently treated with acid, pressed, rolled, and rinsed with water until the salts are removed. Very often the asbestos is mixed with lime, and is then treated with a solution of sodium silicate. This converts the lime into insoluble calcium silicate, and causes the diaphragm to be less subjected to disintegrating action and also to the action of the electrolyte or the products produced upon electrolysis.

Another form of diaphragm cell which has been employed for the electrolysis of fused salts is made of a steel casing, in which another steel case can be fitted concentrically. Between the outer and inner casing, both of which are perforated, a diaphragm mixture of Portland cement and asbestos, or of cement and powdered glass, or burnt magnesite, can be employed.

Bichromatised gelatine has also been employed. A sheet of asbestos is soaked in gelatine or glue and potassium bichromate. It is then exposed to the action of light; by this means an insoluble compound is produced, which is said to form an efficient diaphragm. Even slabs of soap have been suggested and actually employed.

It is well known that percarbonates and perborates, when added to water, yield solutions of hydrogen peroxide. The whole of the peroxide is, however, never yielded up, because an equilibrium is produced. This is due to the fact that perborates, for example, can be produced by the addition of hydrogen peroxide to sodium borate. The Consortium für Elektrochemische Industrie of Nürenberg have patented a process by means of which they can extract the whole of the hydrogen peroxide, German Patent 195,351 (March, 1908). The process consists of adding ether to the solution. The ether extracts the whole of the hydrogen peroxide and thus prevents an equilibrium being set up. The solution, after extraction, only contains carbonates or borates, and by being re-electrolysed the percarbonates or perborates are reproduced. This then gives a method for preparing hydrogen peroxide indirectly from water by electrolytic oxidation. No direct method is at present known.

The directors of the British Aluminium Co. have again declared a dividend of 7 per cent. on the ordinary shares, and carry forward a balance of £36,000, after they have cancelled funding certificates to the amount of £8,900. There has, however, been a decline in profits as compared with 1906. This is attributed to the slump in copper which occurred last July and to the consequent demoralisation in the metal markets. There is no recovery in the price of aluminium to record; therefore the metal has been taken into stock at a much lower price than in previous years. On the other hand, an improved demand has recently set in, and should this be maintained the prospects of the company are rosy.

In the *Times Engineering Supplement* of last week there is an interesting article by Mr. S. Walter upon the "Artificial Production of Rubies and other Gems." Artificial rubies are now being manufactured, and the gems placed upon the market are indistinguishable from those found in the Burmese mines. They are identical in colour, hardness, density, and in refractive power to the natural stones. Their chemical constitution is the same, that is, they are practically pure alumina coloured by traces of chromium and iron oxides. They possess the same power of phosphorescing under the influence of the cathode rays as the natural stone, and they are practically flawless. Now natural rubies usually contain flaws, which always show crystalline structure. The artificial rubies contain flaws which are caused by the occlusion of minute bubbles of gas—they are therefore ellipsoid in structure. Indeed, this is practically the only way in which the natural and artificial rubies can be distinguished. Rubies and sapphires have been produced in the electric furnace, but they are manufactured by allowing the oxy-hydrogen, or, better, the oxy-acetylene flame to play upon powdered ruby cuttings. The cuttings are placed upon a fire-clay platform, which is kept rapidly rotating while the jets from four oxy-acetylene flames play upon them. The mass soon becomes semi-liquid, when the fine ruby powder is added to it, so that the mass gradually increases in size. The maintenance of homogeneity is a matter of great importance, because it is only by effecting this that a bright crystalline gem will ultimately be obtained. When of sufficient size, the molten mass is removed and dropped into a carefully prepared bed of previously heated sand, and allowed to cool slowly. The resulting gem, after cooling, is ready to be cut, and has all the appearance of the natural stone. Cathode rays have recently been employed for melting highly refractory metals; possibly they might be conveniently employed for the production of artificial gems, at any rate, as the operation is carried out in a vacuum there would, we should imagine, be less likelihood for the formation of flaws due to the occlusion of gas.

ELECTRICAL SCIENCE

British and American

Effect of Thermal Treatment on Magnetic Properties.—It is fairly generally known, and was pointed out by Ewing many years ago, that the process devised by Ewing and called "demagnetisation by reversals" is not quite the equivalent of demagnetisation by annealing. The fact is that with most materials the magnetic susceptibility is higher after the annealing process than it is in the same specimen after the process of demagnetising by reversals. Thus, if a rod of iron be annealed from a high temperature and its *I H* curve obtained, and then demagnetised by reversals and again submitted to measurement, the second *I H* curve lies below the first curve. In the April *Proceedings* of the Royal Society of Edinburgh J. G. Gray and A. D. Ross extend our knowledge of these matters. They employed thin rods of various ferro-magnetic materials, and made their observations by the magnetometer method. They pushed their fields up to 125 C.G.S. units, and used for annealing all temperatures from 900° C. downwards. They found in all cases that specimens submitted to thermal treatment are in a sensitive state as regards magnetisation compared with the same material submitted to demagnetisation by reversals. The effect is produced to a slight degree in some cases by temperatures as low as 100° C., but gets larger as the maximum temperature approaches 700° C. After this latter temperature there is little alteration in the sensitiveness produced by annealing. The rate of cooling from the higher temperatures, if not very rapid (as, for instance, by quenching), has little influence on the magnitude of the effect. The sensitiveness is permanent, that is, does not diminish with the mere lapse of time, but mechanical agitation reduces the sensitiveness. Of course, magnetic treatment produces great changes in the magnetic character of the annealed material. For instance, if the *I H* curve for a newly-annealed piece be drawn as the field is increased to, say, 10 units, diminished to −10 units, increased again to +10 units, and so on cyclicly, the ascending loops fall lower and lower and the final *I* is about 20 per cent. lower than the initial *I* at field 10. In general, cyclic reversals of field between definite limits bring the magnetic susceptibility, &c., to lower values for fields lying between those limits. But so long as the field is not changed in sign the sensitive state persists almost unimpaired. The effect of the magnetic treatment is always shown most prominently at that field value where the permeability is greatest, and tends to zero as fields giving saturation are approached. The authors found that the most striking effects are given with hard steel, though similar properties are found in cast-iron and cobalt. The effect is almost absent in soft iron.

The Nature of Gamma-Rays.—At the last meeting of the Physical Society, a Paper by W. H. Bragg and J. P. V. Madsen was read. The former physicist has for some time been urging that the ether-pulse theory of Röntgen rays, and of the gamma-rays from radioactive substances, might, after all, be wrong.

Digitized by Google

and has been advocating a theory of his own. This theory supposes that the gamma-rays, whose principal property is that of being undeflected in magnetic or in electric fields, are streams of uncharged particles--possibly neutral pairs of positive and negative corpuscles. In the present Paper, the authors suggest that in a Röntgen tube the cathode particles that strike the anti-cathode pick up there a positive particle, become neutral and are called X-rays (or Röntgen rays), encounter "absorbing" matter and lose their positive particles, thus figuring as secondary cathode rays. They suggest, further, that throughout all these changes the negative electron maintains almost invariably its original speed. This last point seems to them borne out by the fact that the secondary cathode particles due to Röntgen rays have the same speed, nearly, as the original cathode rays in the tube, and by the analogous fact that the secondary cathode rays due to gamma-rays have the same speed, very nearly, as the beta-particles issuing from the same radio-active material. Apart from these speculations, however, the Paper gives a preliminary account of an experimental investigation which appears to the authors to show finally that the gamma-rays from radioactive matter are material in nature and not ether-pulses. The authors base their argument on the premiss that the secondary radiation excited in an atom by a passing wave or pulse must be symmetrically distributed with regard to a plane passing through the atom perpendicular to the direction of motion of the pulse, and that, therefore, the secondary radiation produced by gamma-rays passing through a very thin plate of matter, should be exactly the same on the two sides of the plate in amount, in quality, and in distribution. Their experiments, corroborating those of Wigger, show that this symmetry does not exist. The present authors' experimental method consists in making the top and the bottom of an ionisation chamber of a pair of thin plates of, say, aluminium and lead. If the secondary radiation produced by these plates under gamma-rays from radium is perfectly symmetrical, it ought not to be possible to discover in which direction the rays are going through the chamber by the mere comparison of the consequence of inverting the pair of top plates with that of inverting the pair of bottom plates. As a matter of fact the direction can be discovered with ease, especially if plates be used of such great difference in atomic weight as aluminium and lead. For example, in one experiment the thickness of each plate was a little less than two millimetres. Inversion of the top plates made a difference of one per cent. in the ionisation current through the gas in the chamber. On the other hand, inversion of the bottom plates made a difference of 44 per cent. According to the authors, the ether-pulse theory of the gamma-rays cannot possibly account for this difference.

The Fundamental Law of Electro-magnetic Induction.—Two statements of the law of induction, discovered by Faraday, are widely used, one due to Faraday himself stating that the induced E.M.F. in a conductor is proportional to the rate at which the conductor is cutting lines of magnetic induction; the other, commonly called Neumann's law, stating that the induced E.M.F. in a circuit is equal to the rate of diminution of the magnetic flux through the circuit. In the March *Proceedings* of the American Institution of Electrical Engineers, C. Hering raises the question whether these statements are really equivalent, as commonly supposed. To show that the statements are decidedly not equivalent he has designed and performed the experiment illustrated here. The conducting loop L, formed of two flexible strips, whose ends are pressed into contact at the joint J, is in series with the galvanometer G. On moving the loop over one limb of the magnet N S, from the dotted position to that shown in full in Fig. 1, an E.M.F. is induced. If now the loop is moved as shown in Fig. 2, from the dotted position to that shown in full, the electrical circuit being kept continuous through the substance of the magnet, there is no induction

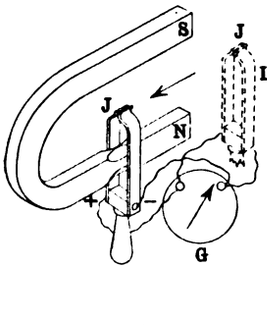

FIG. 1.

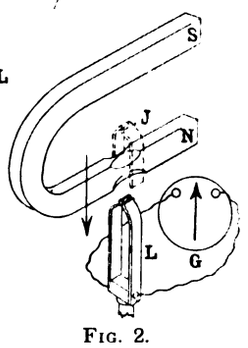

FIG. 2.

whatever of electromotive force. Now according to the "rate of change of flux through circuit" rule there ought to be an E.M.F. induced equal and opposite to that created in the operation shown in Fig. 1. The author urges, therefore, that the true statement of the fundamental law is that of Faraday. It is the material of the conductor of the current, and not merely the circuit itself, which must cut the flux to cause electro-magnetic induction. The converse of this phenomenon has long been known. For instance, in a Faraday disc unipolar machine used as a motor it is neither the circuit nor the current which is rotated through the disc, but it is the disc itself on which the forces act. The author suggests in the Paper a form of continuous-current generator, based on the above experiment with a magnet. The machine proposed has, however, the same limitations as the usual unipolar ones, in that two sliding contacts moving at high speed are required for each element of the circuit which passes through the flux.

Continental

Photoelectric Properties of Selenium.—The debatable question whether metallic or amorphous selenium is the vehicle of photo-electric sensitiveness is discussed by C. Ries in the *Physikalische Zeitschrift* for April 1st. Schrott favours the metallic variety in this respect. But the author points out that when amorphous selenium is heated from 170 to 210° C. it increases in sensitiveness up to 195° and then decreases. At 195° the temperature coefficient of resistance is negative, which clearly indicates a non-metallic structure. Above 200° there is a positive temperature coefficient. The effect of prolonged heating varies according to the temperature. Above 200° C. it diminishes the sensitiveness, whilst below 200° it increases it. When the temperature coefficient of resistance is positive the sensitiveness is negative, *i.e.*, illumination produces, like heat, an increase of the resistance. The author calls this variety of selenium the β-form. The other crystalline variety, which is obtained by prolonged heating at 195° and rapid cooling, may be called the α-form. It has a negative temperature coefficient of resistance and a positive sensitiveness. Light and heat produce a diminution of resistance.

Zeeman Effect.—P. Zeeman himself has applied Fabry and Pérot's interferometer to the observation of the Zeeman effect, and describes his arrangement and results in the *Physikalische Zeitschrift* for April 1st. The interferometer consists of two half-silvered glass plates mounted at a certain distance from each other in strictly parallel planes. This strict parallelism is secured by pressing the plates against round steel buffers by means of springs. The slight compressibility of the steel buffers allows of an extreme accuracy in the adjustment. Zeeman prefers the arrangement in which the distance between the plates is always kept the same. The appearance in the telescope is a set of concentric rings, each showing the succession of colours belonging to the spectrum. On exciting the magnetic field the rings towards the red contract and those towards the violet expand. When the field is strong an expanded violet ring may coincide with a contracted red ring. The second coincidence of this kind occurs at a field of about 15,000 units, and is particularly favourable for exact measurements.

Representation of Electric Lines of Force.—A number of methods have been proposed with the object of making the course and distribution of electric lines of force evident to the eye. The readiness with which magnetic lines of force are made visible has led to the practice of beginning with them, and of treating electrostatic fields by analogy. Seddig's suspension method, though cumbersome, is perhaps the best hitherto devised for electric force. A new and better method is proposed by C. Fischer in the *Physikalische Zeitschrift* for April 1st. He grinds gypsum in a mortar, and so obtains a collection of minute rhombic plates, which are sifted and sorted into various sizes. This crystalline dust is spread on a glass plate, and the electrodes are discs of tinfoil stuck on the glass. The lines mark themselves out on tapping the plate, just as the magnetic lines of force traced with iron filings. The p.d. must not be too high, or the crystals are repelled from the electrodes. The course of the lines of force in various electrical combinations and apparatus may be studied by cutting out pieces of tinfoil representing various sections of the apparatus and sticking them on glass as before. The individual crystals set themselves with their longer axes along the lines of force.

Positive Electrons.—J. Becquerel has succeeded in obtaining some further evidence pointing towards the existence of positive electrons inside atoms, though not, apparently, separable from them. It is given in the *Comptes Rendus* for March 30th. Reversed Zeeman effects have been found in crystals and solutions containing rare earths (Becquerel), in the second hydrogen spectrum and the flame spectra of alkaline earth haloids (Dufour), and in sodium vapour (Wood). Becquerel has now found a similar effect in the spark spectrum of yttrium. This was obtained by sparking over a solution of yttrium nitrate contained in a magnetic field of 20,000 units. There are two groups of lines in the orange part of the spectrum, with terminal lines at wave-lengths 597 and 613·1 respectively. The latter consists of seven lines, and these show the ordinary Zeeman displacement and polarisation. The group at 597 consists of eight lines, and in all of them the effect is reversed. The displacement is the same in all the lines, but is rather less than the displacement of the D-lines of sodium. There is always the alternative explanation of a local reversal of the magnetic field, but if that were accepted it would be difficult to account for the absence of an influence of temperature. The author inclines to the supposition of the existence of positive electrons revolving within the atom.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published April 16th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.
Names in brackets indicate communicators of inventions from abroad.

1906 Patent

29,086. Sir Oliver Lodge. A method of exciting the primary of a Ruhmkorff induction coil by means of the "induction kick" from another inductance coil. The inductance coil is first connected to a generating circuit, then disconnected and discharged through the primary of the Ruhmkorff coil. This operation can be performed by a rotating commutator or other two-way switch. The self-induction of the inductance coil should be one to two henries for a Ruhmkorff coil with a self-induction of one-tenth to one-quarter of a henry. To prevent sparking, capacities are shunted across the inductance and also across the generating circuit. Three claims, five figures.

1907 Patents

7,926. H. S. Hatfield and F. M. Lewis. In order that flame carbons, that is, carbons impregnated with metallic salts, may be burned in an enclosed arc lamp and the life of the carbons thus be lengthened, it is necessary to provide a rapid circulation of the gases in order that the volatilised chemicals shall not be deposited on the globe. (See also Electrical Engineering, February 27th, page 299.) The present invention relates to an improved construction of the side circulation tubes and the supports for the globe, by which the globe is more readily removable for cleaning and for renewing the carbons. The lamp itself is hung in the tubular frame by means of a universal joint, and the globe is connected at the bottom to the hollow frame by means of a flanged tube pressed up against the neck of the globe by a spring. The gases circulate down the tubular frame and up through the globe. Ten claims, four figures.

8,388. British Thomson-Houston Co. (*General Electric Co.*). When arc lamps having electrodes of dissimilar material, for example, carbon and titanium carbide, are operated on an alternating-current circuit, a certain amount of rectification takes place. With several lamps in series, and operated from a constant current transformer, this results in an extremely poor power factor. By connecting half the total number of lamps reversely with respect to the others, the tendency to rectify is overcome. One claim, one figure.

8,629. A. H. Human. For dealing with intermittent or suddenly changing loads in electrical driving, it has been customary to use an auxiliary machine coupled to a flywheel in which energy may be stored up during periods of light load. The present invention renders the use of such an auxiliary machine unnecessary, and can be applied to either continuous current or alternating-current machines. One element of the driving machine, say the armature, is rigidly attached to the driving shaft, and the other element (the field magnet system in the case of a continuous-current machine) is mounted loosely on the shaft, and can rotate about the armature in either direction. The armature and shaft are free to rotate in one direction only. Current is supplied to the machine in such a way that the armature tends to rotate in the direction in which it is prevented from rotating. The heavy field magnet system therefore rotates in the opposite direction, and is allowed to attain a high speed. If the shaft is then needed to drive the load, the electrical conditions between the two elements are altered, the current in the field magnet being increased so as to make the machine act as a generator. As a result the armature and shaft rotate in the same direction as the field system, and the whole will then gradually slow down, doing useful work. An improved arrangement, by which rotation of the driving shaft in either direction can be obtained, is also described in the specification. Two armatures mounted on the same shaft are used in this case, the field-magnet systems rotating in opposite directions. Five claims, two figures.

16,865. A. G. Brookes. (*Asbestos Wood Co.*). A process of manufacturing an insulating material. Asbestos or asbestiform fibre is associated with water and magnesium oxide under pressure and the porous refractory material so obtained, which contains a proportion of magnesium hydroxide as a free oxidising agent, is impregnated with a liquefiable oxidisable hydrocarbon such as ozocerite or any other pitch or asphalt containing ceresin wax. The impregnation is done in a vacuum chamber, and the material is then dried at a temperature of about 80° C. for some days. Four claims. No figures.

17,704. D. Marzi. An improved loud-speaking telephone apparatus, in which the vibrating diaphragm is arranged separate from the magnet system. An oscillating lever which is acted upon at one end by the magnet system imparts its oscillations, considerably magnified, to the diaphragm which may be of any suitable material. According to this invention the rod oscillates in a magnetic field between two poles of equal intensity, one of which is strengthened while the other is weakened at the passage of the current. This ensures that the rod acts positively on the diaphragm in both directions. In a transmitter the short arm of the lever is fixed to the diaphragm; in a receiver the long arm. The windings in which the line current circulates can be on the magnet or on the oscillating rod. Four claims, six figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.
Summaries of the more important of these patents will appear in our next issue.

1907 Patents

4,813, Haydon & Williams. Dynamo-electric transmission of power.
7,642, Lake (*Parker Clark Electric Co.*). Filaments for incandescent lamps.
7,712, Lake (*Ingersoll Rand Co.*). Electro-pneumatic track channellers.
8,036, Craig. Production of ozone from oxygen or air.
8,153, British Thomson-Houston Co. (*General Electric Co.*). Electric motor control systems.
8,974, Nimmo. Train-signalling apparatus.
10,071, British Thomson-Houston Co. (*General Electric Co.*). Supports for the filaments of incandescent lamps.
11,022, Hirst & Leoscher. Lightning arresters.
11,854, Gibbons. Telemotor apparatus.
13,044, Webb. Insulators for telegraph and telephone wires.
14,101, British Thomson-Houston Co. (*Allgemeine Elektricitäts-Ges.*). Control of winding gear.
17,147, Southam. Electrically-operated fountains.
17,781, Jones. Electric arc lamps.
17,783, Meyer. Electro-magnetic reversing coupling.
17,972, Siemens & Halske Akt.-Ges. Manufacture of electric lamps.
18,033, Bodell. Apparatus for locking electric light glow lamps to holders.
18,406, Ewart. Electric switches.
19,027, Chaumat. Electrolytic process for the preparation of indigo dyes.
19,975, Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges.*). Apparatus to control railway points.
22,745, Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges.*). Telephone exchanges.
24,135, Allgemeine Elektricitäts-Ges. Alternating current commutating machines.
24,769, Wolhaupter. Insulated railway rail joints.
25,430, Bollée. Vertical motors.
25,832, Wolhaupter. Insulated railway rail joint.
25,833, Wolhaupter. Insulated railway rail joint.
26,531, Ges. für drahtlose Telegraphie. Receiver for wireless telegraphy.
26,647, Palmer. Electric alarm clocks.
26,925, Unterberg & Helmle. Insulation of magneto-electric sparking apparatus.
28,212, Hoffe & Jelfs. Electrical locking apparatus for railway signals.

1908 Patents

328, Lertourné. Electric motors.
549, Trumpler. Electrical heating apparatus.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

3,583, Seibt. Radio-telephony.
6,050, Siemens & Halske Akt.-Ges. Process for hardening tantalum.
6,051, Siemens & Halske Akt.-Ges. Process for hardening tantalum.
6,245, Westinghouse Metal Filament Lamp Co. Metal filament electric lamps.
6,587, Eiséer & Holmström. Microphones.
6,737, Felten & Guilleaume-Lahmeyerwerke Akt.-Ges. Non-inductive resistances.
6,764, Soc. Ch. Legrand et Cie. Electrically-controlled locks for carriages.
6,765, Engel. Contact device.
6,767, Soc. des Télégraphes Multiplex (Système E. Mercadier). Mono-telephone relay transformer.
6,895, Siemens & Halske Akt.-Ges. Electrical indicators.
7,045, Noe (Cepath). Dynamo-electric machines.

Expiring Patents

No patents of electrical interest expire during the current week.

THE EFFECTS OF LAYING CABLE DIRECT IN THE GROUND

(By a Correspondent)

MODERN practice in the manufacture of cable has gone very largely in the direction of insulating the conductor with paper strip impregnated with resin or other oil, and moisture is kept from the installation by means of a lead sheath. It is highly important, therefore, that in the first place no pin-holes or other fissures should allow water to percolate to the insulation of the cable, and, secondly, that nothing should attack the lead to eat it away.

The presence of tramway systems involving heavy return currents has caused a good deal of trouble with regard to electrolysis, and, for this reason, some systems of lead-covered cables which have been laid direct in the earth have proved a considerable nuisance. In one case some paper cables which were originally laid direct in the ground with concrete over the top, a board being placed over that to indicate the position of the cable to a navvy with a pick, were connected to services, also lead covered, by means of a tee piece consisting of a joint box filled with bitumen; there was no provision for bonding, and, to prevent the bitumen from running out at the ends of the box, these were stopped with clay. The soil in which these cables were laid was hard clay with an admixture of chalk, and was fairly dry. When the boxes were taken off, the lead in some cases was thin and hard and had a white deposit on the places where the clay had been put around it to stop the bitumen from running out. Moreover, the lead on the main had a white pitted appearance, which the workmen described as "smallpox," and when it was handled a white dust was left in the hand. The cable also left its shape in the earth with a white film of deposit. There was a considerable number of faults in the cable, which may have been the cause of the hardness of the lead. These boxes were taken off and the joints sealed in bitumen with troughing, and the lead bonded with copper wire soldered to it. This got rid of electrolysis effects.

One big mistake in connection with lead-covered cable is to make the services tapped off such a main of rubber. This gets over any local trouble at the entrance of the house, but is liable to concentrate the bad effect of electrolysis on the main itself. Theoretically, the best solution is to run the whole system up solid in troughs with bitumen, but so far as can be ascertained this has never been done completely, and it would be a very difficult thing to do.

A suggested system is as follows:—In using lead cables these should be laid solid and insulated as far as possible, the cables being well juted and a light network woven over this juting, consisting of wire having as high a conductivity as possible. Iron wire or some aluminium alloy might be used. This outer sheath could then be earthed wherever possible, and should not only form a strong protection against stray currents but should keep the jute in place. This arrangement would get over the trouble not infrequently found in drawing in cable in conduit or iron pipes, of the jute rucking up, leaving the lead sheathing uncovered.

The alternative to running up the installation solid and insulating it, is to reduce the lead to earth potential as much as ever possible by bonding and earthing it at every possible point. At joint boxes and inspection boxes the bond should be carried between the different sections of cable entering the box by means of a copper wire passing to the box cover, this cover and the box being then effectually earthed. Where wrought-iron pipes are used as conduits it will be found that moisture accumulates very much, and if lead-covered cable is drawn into such pipes the water will form an effective conductor from the lead sheathing to the iron of the pipe, which will be at earth potential.

These notes may be of some use in directing the attention of some other engineer to the best expedient to be adopted in his particular set of troubles.

LOCAL NOTES

ARBROATH: *Electric Lighting.*—Considerable progress has been made in the erection of the works of the Arbroath Electric Supply Co., and it is expected that a supply will be given by the end of June. An agreement has been entered into with the Town Council for public lighting.

ABERDEEN: *Tramways.*—It has been decided that in future the sum of £70 per annum instead of £140 per annum be paid to the Electricity Committee for services rendered by the electrical engineer to the tramways department.

BARNES: *Electricity Finances.*—On the recommendation of the Finance and General Purposes Committee, part of the sum now in the treasurer's hands (£1,500) is to be transferred from the District Fund and placed to the credit of an account to be called the electricity revenue account.

BECKENHAM: *Municipal Electrical Association.*—At the last meeting of the Council a long discussion took place upon a recommendation that the electrical engineer be authorised to attend the annual convention of the Incorporated Municipal Electrical Association. The arrangement suggested as to the engineer's expenses was that he be allowed up to £10, which should be added to his salary for the current year. Several councillors objected to the proposal on the ground that it would be a waste of money, and doubt was expressed whether the auditor would pass the amount when it came before him. Mr. Dykes, in supporting the recommendation, said that the papers read at the convention of the Incorporated Municipal Electrical Association were thoroughly practical, and perhaps still more useful were the informal discussions that the members had amongst themselves. In the result the committee's recommendation was adopted by 8 votes to 4.

BELFAST: *Cavehill and Whitewell Tramways.*—A conference has been held between the Tramways and Electricity Committee and the directors of the Cavehill and Whitewell Tramways Co. to consider the position created by the rejection of the Bill for the acquisition of the company's undertaking by the Corporation. It is stated by the local papers that a working agreement has been arrived at which will shortly be placed before the Corporation for confirmation.

The proposal under consideration is as follows:—"The Corporation to rent so much of the company's undertaking as defined in the agreement for a period of four years, and to pay by way of rent therefor 3½ per cent. per annum on the proposed purchase price of £60,000; also to pay into the credit of a joint account to be opened in the name of the Corporation and the company 2 per cent. per annum, if earned, on the same amount (these two items of 3½ and 2 per cent. making together the interest and sinking fund which the Corporation would have had to find to pay the interest on and pay off the £60,000 purchase-money in thirty years), the annual payment of 2 per cent., if earned, with accumulations, to become the property of the Corporation if they decided to, and were empowered to, acquire the undertaking before the completion of the four years; and, in the event of their deciding not to purchase, or being unable to obtain power to purchase, as aforesaid, this sum to become the property of the company."

BIRMINGHAM: *Proposed Home Office Regulations.*—At a meeting of the Birmingham Chamber of Commerce last week, the recent inquiry into the proposed Home Office Regulations regarding the use of electricity in factories and workshops was discussed, the Secretary stating that with evidence based on theory alone the Home Office had attempted to impose a most unreasonable burden upon the industry. A motion by the Chairman that the General Purposes Committee be instructed to report as to the powers of interference placed in the hands of the Home Office under the Factories and Workshops Act, 1901, was seconded and carried.

BOURNEMOUTH: *East Cliff Electric Lift.*—The new electric lift on the east cliff at Bournemouth was opened on Thursday.

BRIGHTON: *Electricity Charges.*—The revisions in the charges for electric lighting referred to recently have now been placed before the Council in detail. Mr. J. Christie, the electrical engineer, expressed the opinion that some revision has become necessary in consequence of the increased price of coal which represents approximately two-thirds of the total costs. He claims, however, that the new rates will not operate harshly upon the consumer in consequence of the more economical lamps now available. It is proposed that the new rates should come into force on July 1st. For ordinary lighting purposes in hotels, clubs, churches, &c., the charge will be 3d. per unit, for shops and private houses 4d. per unit, and for arc lamps on independent mains with separate meters 3d. per unit. A special tariff has also been prepared for large consumers over 20,000 units per annum, by which the price is reduced to 1d. per unit when the consumption exceeds 40,000 units per annum. For power heating and cooking through separate meters, without restriction as to time, the charge is 1½d. per unit, whilst with a time switch cutting off supply between 5.30 p.m and 8 p.m. during January and December, the charge will be 1d. per unit After the next June meter reading consumers now being supplied upon maximum demand system will have the option of continuing at the following revised rates:—For the first hour's average daily use of maximum demand, 6d. per unit and 2d. per unit for all consumption in

Digitized by Google

excess. The above charges only apply within the Borough of Brighton. For lighting outside the borough without restriction as to time the charge will be 4½d. per unit, and for power heating and cooking 2d. per unit. One month's notice of the change will be given to the consumers. No new consumers will be taken on the demand indicator system

COLWYN BAY: *Tramway Extension.*—Mr. S. Sellon, the managing director of the Llandudno and District Electric Tramways Co., has written to the Council intimating that he will be prepared to continue the tramways to Rhos on condition that the Council do not make the acquisition of certain land a condition precedent to the extension. The Town Clerk has replied that the Council do not require this land to be purchased, and urged the company to pay the Council the agreed sum of £3,000 for the necessary road widenings.

CROYDON: *Supply Outside Borough.*—The Corporation is to supply current to house premises outside the Borough boundary and within the area of supply of the South London Electric Supply Corporation, Ltd., subject to an agreement by which the Corporation pay a nominal sum per annum by way of rent, and covenant to remove their cables upon one month's notice to do so.

DUNFERMLINE: *Electric Lighting.*—The offer from Messrs. Gibbings & Chauntler, of Liverpool, to undertake to prepare an electric lighting scheme for the Council is to be considered by the Council, and if necessary it will be forwarded to Sir Alexander Kennedy for report.

EAST HAM: *Tramways.*—The Council has decided to purchase from the North Metropolitan Tramways Co., subject to the consent of the Board of Trade, all portions of the Romford Road lines belonging to the company (exclusive of depôt and all rolling stock) at the sum agreed upon between the Council and the company, viz., £8,000.—The Borough Treasurer has recently been in communication with the Surveyor of Taxes relative to the amounts payable to the Inland Revenue in respect of income tax on the electric lighting and tramways profits for the year 1907-8, and the Finance and General Purposes Committee has directed him to endeavour to obtain an allowance for depreciation in respect of the whole capital expenditure on each undertaking.

FINCHLEY: *Electricity Finance.*—At the meeting of the Council recently, at which the half-yearly rate was fixed, the Chairman of the Finance Committee said that the electricity undertaking was estimated to produce a gross revenue of £12,888. After allowing for interest accrued, but not payable in the year under review, it will repay a sum of £6,893 in connection with its sinking fund charges, an amount which, in a private concern, would enable a very handsome dividend to be paid. After making due provision for necessary depreciation and reserve fund the net surplus of the undertaking for the twelve months was expected to be £100.

HASLINGDEN: *Tramway Intercommunication.*—It was reported to the Haslingden Electricity Committee on April 15th that arrangements had been completed for the through running of electric cars from Accrington to Rawtenstall. It has been decided that arrangements be made for Accrington to run its electric cars to Haslingden immediately the track, standards, and overhead equipment are ready—this as a temporary measure until Haslingden is able to obtain current from the generating station about to be erected in this locality. It is not expected that this station will be ready for at least nine months.

ILFORD: *Tramway Intercommunication.*—At the last meeting of the Urban District Council a letter was received from the Board of Trade inquiring if the Council would attend a conference with the Barking authority on the subject of the interrunning of the trams, to be presided over by a chairman appointed by the Board of Trade. It was stated that the Board of Trade had no power to compel either authority to consent to any particular arrangement, but it was resolved that the conference be attended.

LEYTON: *Motor Hiring.*—At the last meeting of the Council the opinion was expressed that if the Council would let motors on hire, this would have the effect of bringing many tradesmen on to the electric supply mains. The Chairman of the Electricity Committee pointed out that the Council had no powers to borrow money in this connection, and would have to pay for them out of revenue. He thought the best way to induce new consumers was to reduce the price of electrical energy.

LIVERPOOL: *Telephone Charges.*—The Finance Committee of the Corporation has reported upon an agreement made between the Corporation and the National Telephone Co., in June, 1896, in which the charges for unlimited service were set out as follows:—For the first connection within one mile of any exchange, £10 per annum; for each quarter mile or portion of quarter mile beyond the first mile, £1 5s. per annum; for the second connection and each additional connection within one mile of any exchange, £8 10s. per annum; and for each quarter mile beyond the first mile, £1 5s. per annum. In return for the right to apply the measured rate to all new subscribers, the National Telephone Co. have agreed to allow existing subscribers to continue their agreements, and to allow them to transfer to new offices, if necessary, and still continue their agreement and not insist on the measured rate, in the event of a subscriber requiring additions to existing installations. The Finance Committee of the Corporation report that, the Company having agreed to these terms, they recommend the Corporation to agree also on their part.

LONDON: *Paddington. Street Lighting.*—The Borough Council, at a special meeting, decided the interesting question of the lighting of a portion of Harrow Road which has been under consideration for some considerable time. The Metropolitan Electric Supply Co., Ltd., and the Gas Light & Coke Co. lighted, as an experiment, certain lengths of the thoroughfare for the purpose of comparison between the present and the proposed gas schemes with the proposed electric flame arc lamp scheme. The cost of the present system of gas lighting is £198 per annum (*i.e.*, 66 lamps at £3). The Gas Light & Coke Co. offered an improved system on the following terms:—66 lamps at £4 12s. 6d., or £305 5s. per annum, the initial cost being nil. If the lamps were taken over from the company at the end of five years the Council would pay £164, but in the event of the proposed arrangement lasting for ten years, the lamps would become the property of the Council without payment. The lamps would consist of two kern burners in improved lanterns. The Metropolitan Electric Supply Co., Ltd., offered an improved system of 24-flame arc lamps at an average of £13 each, *i.e.*, £312 per annum. The initial cost would be about £170, and the offer was made on the understanding that the arrangement would be in force for seven years. The Works Committee recommended the acceptance of the offer of the Metropolitan Electric Supply Co., Ltd. The Finance Committee observed that the proposal opened the question of electric lighting for the whole borough, which would involve additional expense. After considerable discussion the recommendation was lost.

Woolwich: New Tramways.—A trial trip has been made upon the new tramways from Beresford Square to Plumstead Church. This line effects a junction with the Bexley Urban District Council tramway undertaking.

KINGUSSIE: *Electric Lighting.*—Estimates for an electric lighting scheme have been placed before the Council, the cost being £3,000, but it has been decided to leave the matter over for the present.

KIRKINTILLOCH: *Tramways.*—The Town Council has received a letter from the Glasgow Corporation intimating that the Glasgow Tramways Committee do not see their way to recommend the extension of the tramway system to Kirkintilloch. The general opinion of the Glasgow Corporation Tramways Committee is that for the present the tramway system should not be further extended outside the city boundary.

LOWESTOFT: *East Anglian Light Railway.*—A sub-committee of the Tramways Committee recommend that the Council should come to some decision with regard to the East Anglian Light Railway and put forward three possible courses of action:—(1) The Council to construct and work the line; (2) the Council to construct and lease the line; (3) to sell the concession outright. After some discussion a resolution was passed, sending the report back for reconsideration.

LONDONDERRY: *Municipal Electrical Association.*—At the meeting of the Corporation, on the 16th inst., the question of sending delegates to the annual conference of the Incorporated Municipal Electrical Association at Nottingham in June next was discussed. A councillor strongly objected to the sending of two delegates on the score of expense, adding that he had never met a member of a deputation who was able to point to one particle of good resulting. Mr. R. V. Macrory, the Electrical Engineer, was called in and questioned on the utility of these conventions. He said that as the result of a conversation at the last conference he was enabled to save £37 per annum on one boiler. It was finally decided to send the engineer.

MIDDLESEX: *Tramway Extensions.*—An extension of the Metropolitan Electric Tramway system from Harrow Road to Wembley has been opened.

MUSSELBURGH: *Public Lighting.*—In reference to the recent complaints with regard to the street electric lighting, which is carried out by the Musselburgh & District Electric Light & Traction Co., the Town Council has decided that in the event of no perceptible improvement being shown during the next quarter, the lighting bill shall not be paid, and that the Borough Surveyor shall be instructed to prepare an estimate of the cost of re-erecting the gas lamps.

ROCHDALE: *Tramway Accounts.*—The electric tramways gross receipts for the past year are £56,557, an increase of £2,000 on the preceding year. Working expenses rose from £29,505 to £33,043. The deficiency on the working for the year is £2,102, which, with £1,946 arrears on sinking fund, gives a total deficiency to be provided out of the rates of £4,048. The electricity department's income for the year was £20,378, an increase of £3,092. Expenses were £11,014, an advance of £2,552. Gross profits £9,364, against £8,824. There is a surplus of £4,299, and £2,000 will be devoted to relief of the rates.

ROCHESTER: *Tramway Extensions.*—The Rochester lines of the Chatham and District Light Railway Co. were put into operation on Thursday.

ST. ANNE'S-ON-SEA: *Tramway Electrical Energy.*—The Blackpool, St. Anne's, and Lytham Tramways Co. has made an application to the Urban District Council for a revision of the charges now made for supplying the undertaking with

Digitized by Google

electrical energy. The application has been referred to a sub-committee of the Electric Lighting Committee.

STAFFORD: *The Electrical Undertaking.*—At the last meeting of the Town Council, the Chairman of the Gas and Electricity Committee stated that for the past five weeks the output of electricity showed an increase of 12½ per cent. compared with the corresponding period of last year.

SWINDON: *Electricity Works.*—In view of the proposed extensions of plant at the electricity works, the electrical engineer has been authorised to visit some electricity works where steam turbines are in use, and to report to the Electricity and Tramways Committee.

TORQUAY: *Torbay Road Tramways.*—Successful trial trips have been made upon the extension of the Dolter system in Torquay, along Torbay Road.

WHITEFIELD: *Electric Lighting.*—In reply to an inquiry from the Town Clerk, the company which has acquired the Urban District Council's electric lighting order state that the delay in erecting the works has been brought about by the recent state of the Money Market, but that all arrangements have now been concluded for raising £150,000 capital.

WINNIPEG: *Telephone Purchase.*—A Reuter telegram states that the Minister of Public Works for Alberta officially confirms the announcement that the Alberta Government has purchased the Bell Telephone system in the province for $675,000.

WORTHING: *Electricity Undertaking.*—The account of the finances of the Corporation for the past half-year shows that the electric lighting undertaking has resulted in a loss of about £20. The Deputy Mayor stated that the expenditure had been greater than was anticipated, owing to the faulty working of the condensing plant, and that an application had been made for a loan for the provision of an up-to-date plant.

YARDLEY: *Electricity Supply.*—Since the Urban District Council entered into an agreement with the British Electric Traction Co. for the purchase of the power station at South Yardley not much progress has been made with regard to the supply of electricity in this district. A full report on the subject, however, is promised very shortly. The purchase price of the power station has been fixed at £15,000, less £2,500 for depreciation, and the Council will have to remove at its own cost all the plant from the company's premises to the new power station, which is to be erected at Hay Mills. Should the plant not be removed within twelve months from the date of the Board of Trade consent to the agreement, a rent of £50 per annum is to be charged.

YEOVIL: *Revocation of Electric Lighting Order.*—The Board of Trade has revoked the Yeovil Electric Lighting Order, 1903.

TENDERS INVITED AND PROSPECTIVE BUSINESS

ABERTILLERY.—The Local Government Board has communicated with the Council to the effect that the Board is not satisfied that the establishment of an electric lighting installation in accordance with the scheme recently formulated, would be a financial success. The Council has decided to ask the Local Government Board to receive a deputation on the matter.

AUSTRALIA.—The Board of Trade correspondent at Melbourne (Mr. M. Hirsch) has forwarded particulars of a call for tenders for the supply to the Deputy Postmaster-General at Melbourne of 2,800 jacks in strips of 20; 1 mile of 64-wire switchboard cable; 50 three-conductor cords, 7 ft. long; 96 three-part plugs; and 66 listening and ringing keys. Tenders will be received by the Deputy Postmaster-General, Melbourne, up to 3 p.m. on June 9th.

The Board of Trade are notified by the London representative of the Australian Commonwealth (Capt. R. Muirhead Collins, C.M.G.) that tenders will be received at the office of the Deputy Postmaster-General, Perth, until noon on Monday, September 7th, for the supply of the following telephone material, viz.: 650 wall sets, 150 table sets, 800 protectors, 90 extension switch and bell sets, complete, 30 switchboards for four lines, 20 switchboards for six lines, 5 switchboards for twelve lines, 5 switchboards for twenty-four lines, 20 wall sets for party lines, and 10 table sets for party lines. Tenderers must state the country in which the articles tendered for have been made or produced, and, in the case of manufactured articles, where the material has been made or produced. Tenders must include customs duty, if any. A deposit, equal to 5 per cent. of the amount of the offer, will be required to qualify any tender. Specifications, conditions, and forms of tenders may be obtained at the Commonwealth of Australia Offices in London, 72 Victoria Street, S.W.

AYR.—Extensions to the electricity works are to be carried out at an estimated cost of £15,050.

BELGIUM.—H.M. Consul-General at Antwerp (Sir C. Hertslet) has forwarded a copy of a specification issued by the Municipal Authorities of that city in connection with a call for tenders for the supply and fixture of two electric lifts in premises belonging to the Municipality in the Place de Meir, Antwerp.

BLACKPOOL.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £5,000 for the purposes of the electricity undertaking. The greater portion of this sum will be for mains. Mr. C. F. Furness, the Electrical Engineer to the Corporation, stated that whereas in 1903 the profit on the electricity undertaking was £2,352, it has steadily increased year by year, and for the last complete financial year the profit was £8,229.

DUNDEE.—Tenders are invited for the following:—(*a*) steam, exhaust, feed water, and drain piping system, with two steam-driven feed pumps and two hotwell tanks for main generating station; (*b*) equipment of circulating water pump room, including two electrically-driven vertical-spindle centrifugal pumps, in connection with the main generating station; (*c*) circulating water-pipe system (about 1,500 feet long), in connection with the main generating station; (*d*) overhead travelling cranes for main generating station and two sub-stations. Full particulars from the City Electrical Engineer, fee £3 3s., returnable, and tenders to the Town Clerk by April 27th.

ECCLES.—Tenders are invited for: (1) a Lancashire boiler and superheater; (2) a 210 kw. steam generating set and exciter. Particulars from the Borough Electrical Engineers (fee £2 2s., returnable), and tenders to the Town Clerk by April 27th.

GLASGOW.—Tenders are invited by the Lunacy District Board for the supply of stores for twelve months ending May 16th, 1909, including electric lamps and fittings. Full particulars from the Inspector and Clerk, 266 George Street, Glasgow, and tenders by April 24th.

The Corporation invite tenders for the supply of main cables, small cables and wires, electricity meters, and arc lamp carbons during the twelve months ending May 31st, 1909. Full particulars from Mr. W. W. Lackie, the Corporation Electrical Engineer (fee £2, returnable), and tenders by April 27th.

GOVAN.—Tenders are invited for the supply of the following stores for the year ending May 15th, 1909: Oil, waste, and engine-room stores; cables; cable accessories; bitumen and compound for joint boxes; electricity meters; house service fuse boxes; wrought-iron tubes and fittings; cast-iron pipes; arc lamp carbons; coal; joint boxes; motors; motor starters and D.P. switches. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by April 27th.

HASLINGDEN.—Tenders are invited for overhead tramway lines with tangential suspension, telephone system, and tower wagon. Particulars from the consulting engineers, Messrs. Handcock & Dykes, 1 Victoria Street, Westminster (fee, three guineas, returnable), and tenders to the Town Clerk by April 25th.

HESTON AND ISLEWORTH.—The District Council, at its last meeting, were informed by the Finance Committee that the loan of £1,400 for laying a new electricity feeder for the Hounslow district could be provided out of the redemption fund, and they would recommend that application be made to the Local Government Board for an Order to enable this course to be taken, provided the Electricity Committee were willing to pay interest at 3½ per cent. on the advance.

KIEL (GERMANY).—It is stated that among the new works to be carried out at the Kiel shipyard during the current financial year is an electric power station.

LONDON: *London County Council.*—Tenders are invited for the wiring and fitting for electric lighting of a tramway car shed at Mare Street, Hackney. Particulars from the Clerk, fee £2 2s., returnable, and tenders by May 12th.

Tenders are invited for the supply and delivery of (*a*) 175 double-deck, roof-covered, electric car-bodies; (*b*) 175 pairs of maximum traction swing bolster trucks; (*c*) 175 complete electrical equipments for operation upon the overhead trolley, surface contact, and underground conduit systems of electric traction. Full particulars from the Clerk to the Council (fee £2 2s. returnable), and tenders by May 9th.

Poplar.—The Electricity Committee invite tenders for the erection of a sub-station building at Millwall in brick, ferro-concrete, or corrugated iron. Full particulars from the Borough Electrical Engineer, fee 5s., not returnable, and tenders to the Town Clerk by April 29th.

In regard to the Borough Council's extensions to the electricity undertaking at an approximate cost of £27,209, the Borough Engineer has reported that it is essential the extensions should be completed by the end of October next, and in order that there may be no delay, the Finance Committee has submitted an estimate, and has also decided that application be made to the L.C.C. for a loan of not exceeding £24,000, subject to the Borough Council subsequently resolving to carry the scheme into effect, and to revision of the amount of the loan in accordance with tenders which may be accepted. The estimated amounts chargeable to capital account are:—Millwall sub-

Digitized by Google

station, land and buildings, £800; mains, £5,552; machinery, £16,560; house connections, £250; meters, £250; contingencies, £365. The expenditure chargeable to revenue account in respect of dismantling, removing, and re-erecting converter, dismantling a generating set, reclaiming and relaying feeders, and connecting feeder to northern sub-station, is £3,432, subject to revision on ascertained cost of the work. To this sum has to be added £1,400, cost of displaced set, less the amount to be realised by sale thereof, which it is proposed should be fixed at a minimum of £700, making a total of £4,132, to be written off the amount of the existing working balance and the current year's profit.

LOWESTOFT.—The Electricity Committee recommend that application should be made to the Local Government Board for a further loan of £1,000 for "free" wiring purposes.

RAWTENSTALL.—Tenders are invited for the supply, delivery, and erection of steel tramway poles, overhead line equipment and accessories. Full particulars from the Consulting Engineers, Messrs. Lacey, Sillar, and Leigh, 2 Queen Anne's Gate, Westminster, and 78 King Street, Manchester (fee £3 3s., returnable), and tenders to the Town Clerk by May 4th.

ROCHDALE.—The Board of Guardians recommend that a new storage battery be installed at the workhouse.

TENDERS RECEIVED AND ACCEPTED

ABERDEEN.—The tender of Messrs. Milne, Voss & Co., for six additional car top covers at £130 each has been accepted.

AUSTRALIA.—The Victorian Postmaster-General's Department has accepted the following tenders :—1,000 cords, two conductor, for metallic circuits, British Insulated and Helsby Cables, Ltd.; 6,000 yards cords, single conductor, 4,000 fuses, and 2,000 lead strips and attachments for Meidinger main battery, the India Rubber, Gutta Percha, and Telegraph Works Co., Ltd.; 200 conversers for wall telephones with cord, plug, and jack complete, 1,000 ear pieces for receivers, and 4,000 fuses and holders, Messrs. J. Bartram & Son (Melbourne); 1,000 indicators, 100 ohms resistance, and 500 metallic circuit jacks, Messrs. R. B. Hungerford (Sydney); 2,000 insulators, 50 switches, and 1,500 incandescent lamps, Messrs. J. A. Newton & Co. (Melbourne).

BELFAST.—The tender of Messrs. J. S. Scott & Co., for 170 gun-metal key-hole covers for tramway feeder pillars, has been accepted.

CALCUTTA.—Three replies were received by the Corporation in response to its advertisement asking for tenders for street lighting. The *Calcutta Statesman* says that the present contract for lighting the city with gas expires in April, 1911, and in order to have sufficient time to consider the new tenders, offers were called for by January 1st of this year. Three tenders were received, namely, from the Calcutta Electric Supply Corporation, the Oriental Gas Company, and Messrs. Hughes and Stirling. At a special meeting of the Corporation last month, it was stated that the tender of the latter firm was not treated seriously, as it was contingent upon the Corporation giving an order for the erection of a refuse destructor. The offer of the Calcutta Electric Supply Corporation was to light the centre of the city extremely well, and the suburbs rather poorly. A total of 10,673 lamps were to be installed, of which 9,276 would be 35 c.p., 902 would be 70 c.p., and 495 of 1,500 c.p., and the charge for a 20 years' contract was to be Rs.6,54,556 (£43,637) per annum. An amended tender has since been received, in which are included 150 arc lamps of 1,500 c.p. and 9,177 of 70 c.p., at an annual cost of Rs.5,82,281 (£38,818). The 70 c.p. lamps would be metallic filament lamps, and it was stated that the engineer to the Corporation was not impressed with this type. In rejecting the tender of the Electric Supply Corporation, the Electricity Committee stated their reasons were (1) that the light proposed to be given was less and the charge more than that proposed by the tender of the Gas Company, and (2) that as the Corporation has the option of purchasing the Supply Company in October, 1919, it would probably double the purchase price if this contract were given to them. The Gas Company's offer was for 9,225 lamps with a maximum of 60 c.p. and minimum of 20 c.p., in addition to 84 special lamps of 700 c.p. The annual cost under the Gas Company's tender will be Rs.5,11,758 (£34,117). Considerable discussion took place upon the tenders, and, after a debate lasting nearly two hours, the matter was adjourned for three weeks for a poll of the ratepayers to be taken.

CROYDON.—The Corporation has accepted the following tenders for Electricity Works requirements :—Coal and ash conveyor, Babcock & Wilcox, Ltd., £1,154; coal and ash bunkers, Weber Concrete Construction Co., Ltd., £681 14s.; builders work, Electricity Works Department, £205 17s.; switchboard flooring, St. Pancras Ironworks Co., Ltd., £144. The following tenders have been accepted for the supply of coals to the Electricity Works :—Large Welsh coal, Cory Bros & Co., Ltd. (for three months); large hard steam coal, J. H. Gilman & Co. (from May 1st to March 31st next); small nut coal, J. H. Gilman & Co. (for six months).

EAST HAM.—The Electric Lighting and Tramways Committee has decided to accept the following tender of Mr. W. R. Reynolds for fixing and supplying the necessary installations (exclusive of lamps) in connection with the hiring of arc lamps by consumers :—For 2-lamp installation, £2 17s. 6d.; for 4-lamp installation, £5 15s.; for 6-lamp installation, £8 12s. 6d. A letter has been received from Messrs. E. Foster & Co., stating that owing to the reduction of price at the colliery they are prepared to reduce their price for the supply of 1,500 tons of Ibstock fine slack coal during the ensuing year from 10s. 6d. to 10s. per ton. The accepted tender of Messrs. Foster & Co. was for 10s. 6d. per ton. The Committee has decided to accept the tender of Messrs. Thos. Moy, Ltd., for 500 tons of yard slack coal at 11s. 6d. per ton, and that of Messrs. M. H. Abbott & Co. for 365 tons at 11s. 6d. per ton.

HESTON AND ISLEWORTH.—The District Council has received the following tenders for the wiring and fitting of the Isleworth Bath for electric lighting :—E. A. Hellyer & Co., £17 15s.; G. Weston & Sons, £17; T. Hiscock, Hounslow (accepted), £17.

HOLLAND.—A concession has been granted by the Dutch Government to the Amsterdam and North Holland Electric Tramway Company to construct and operate a system of electric railways in Holland. The system comprises about 50 kilometres of route running from Amsterdam north through Zaandam to Krommenie, from Zaandyk to Wyk-aan-Zee, and Wormerveer to Purmerend. The Amsterdam and North Holland Electric Tramway Company has entered into a contract with the Holland Development Company, 278 Heerengracht, Amsterdam, to construct the entire system.

NELSON.—The tender for the supplying of the electrical fittings to the Council's new school has been let to Messrs. Carter & Co., of Nelson.

LEEK.—The tender of T. Grace, of Leek, at £1,598, for the engine and dynamo foundations for the extensions to the generating station is recommended for acceptance.

LYNN.—The tender of Messrs. Chamberlain & Hookham, Ltd., for the supply of 50 meters, has been accepted.

SWINDON.—The tenders of Messrs. Babcock & Wilcox, Ltd., for a superheater, at £175, and that of Messrs. Aiton & Co., for feed pipes, at £137, have been accepted.

TASMANIA.—The Postmaster-General's Department has accepted the following tenders :—One mile of paper insulated and lead-covered cable at £50 7s. 10d., British Insulated and Helsby Cables, Ltd.; 200 three-inch cast-iron pipes, at £9 19s. 4d. per ton, Messrs. Mauri Bros., and Thomson (Sydney).

COMPANIES' MEETINGS AND REPORTS

BABCOCK & WILCOX.—The report for the year 1907 shows a net profit of £309,769, to which has to be added the balance brought forward, viz., £25,895, making a balance of £335,664. After deducting the interim dividends on the preference shares and ordinary shares, there is a balance of £266,264. The directors recommend a dividend of 3 per cent. on the preference shares, less tax, 8 per cent. on the ordinary shares (free of income tax), and a bonus of 4 per cent. on the ordinary shares (free of income tax). In addition, there is to be placed to the reserve fund the sum of £100,000, and to the dividend equalisation fund, £25,000, leaving a balance to be carried forward of £38,664. The extensions of the works referred to in last year's report have been completed and are in working order, and have enabled the increase in the business during last year to be dealt with. The volume of orders on hand at December 31st, 1907, and carried over for execution in 1908, is considerable. The meeting is to-morrow.

CITY OF BIRMINGHAM TRAMWAYS.—The report for 1907 shows a surplus, after providing £12,000 for interest on debentures and £12,083 the dividend on preference shares, of £35,772, from which is deducted the sum of £2,104, being the interim dividend of 5 per cent. on the ordinary shares, leaving a balance of £33,367. The directors recommend a dividend on the ordinary shares of 5 per cent. per annum for the six months ended December 31st, together with a bonus of 5 per cent., making 10 per cent. for the year amounting to £6,314; to trans-

Digitized by Google

ferring £27,353 to reserve fund, increasing that fund to £459,121. The expenditure on capital account during the year amounted to £8,696, and includes part of the cost of reconstructing the Stratford Road tramways in Yardley for electric traction. A sum of £21,676 has been received from the sale of old rolling stock and of the overhead equipment and cables in Coventry Road and John Bright Street to the City of Birmingham, and has been credited to capital account. The traffic receipts compared with the previous year show a reduction of £131,000, due to the termination on December 31st, 1906, of the leases of the steam tramways in Birmingham and the sale, as at that date, of certain of the tramways in King's Norton and Handsworth. The shrinkage in the receipts has been slightly less than was anticipated. The expenses have been proportionately reduced, and £12,200 less was paid for rental of lines than in the previous year. Owing to the competition of the Corporation tramways, and the excessively heavy cost of repairs and maintenance of the motor omnibuses and the prevalence of bad weather, the result of the past year's working of the omnibuses has been very unsatisfactory. On October 5th last the motor omnibuses were withdrawn from service. The company has joined the British Electrical Federation.

BRITISH ALUMINIUM.—The report for 1907 shows a profit of £120,481. From this has to be deducted debenture stock interest (£28,515), and the expenses of issue of new capital, amounting to £7,227, and there has also been appropriated in reduction of the cost of the company's temporary factory at Kinlochleven £10,764. Depreciation absorbs £20,000, leaving, with the balance brought from the previous year, a balance of £88,523. It is now proposed to pay a final dividend on preference shares, balance of interest on funding certificates for the year 1907, interest at 5 per cent. per annum on amounts paid up on conversion shares and 1908 conversion shares, and a final dividend at the rate of 7 per cent. on ordinary shares, making 7 per cent. for the year. There will then remain the sum of £45,489, of which £8,986 has been utilised in purchasing and cancelling 2,196 funding certificates, leaving £36,502 to be carried forward. In comparison with 1906 there has been a decline in the profits, which, the report thinks, may be attributed to the slump in copper last July, and to the resulting demoralisation in the metal markets generally. There has been no recovery in the price of aluminium, so the metal has been taken into stock at a much lower price than in previous years. Customers, however, have latterly been ordering much more freely, and an improving demand may now be counted on. The temporary aluminium works at Leven only began producing during the last week of December, and those at Stangfjord in January last, so that the company derived no advantage from them during the year. Progress continues to be made with the development of the permanent power scheme at Kinlochleven, but there is now no prospect of any power being derived from this prior to the summer of next year, when the various sections of the work should be completed to enable the production of aluminium to be started. The development of the Orsières power scheme is being proceeded with, and a contract has been entered into for the construction of the first portions of the hydraulic section of the works. The construction of the Martigny-Orsières Railway, which was commenced last year, is proceeding satisfactorily. Towards meeting the large capital expenditure which these extensions entail, issues have been made of 40,000 1908 conversion shares of £10 each, 39,070 of which have been subscribed, and of 20,000 "A" 6 per cent. preference shares of £5 each, all of which have been taken up.

DUDLEY, STOURBRIDGE AND DISTRICT ELECTRIC TRACTION.—The report for 1907 shows gross receipts for the year of £46,254. After deducting all expenses, including repairs and maintenance, and placing £2,000 to renewals account, there remains £11,898. Deducting the dividend on the preference shares accrued to December 31st, 1907, and adding the balance of £1,050 brought forward from last account, the sum of £7,948 remains available for allocation, which the directors recommend should be applied as follows:—To sinking fund £1,000, to depreciation and reserve £1,000, dividend of 5 per cent. per annum on the ordinary shares £5,000, carried forward £948. The amount available for distribution is apparently less than in 1906, owing to the directors having decided to charge a larger amount to renewals account before arriving at the balance, rather than appropriating it after ascertaining the balance. The appeal to the House of Lords by the Corporation of Dudley against the decision of the Court of Appeal on the special case as to the basis for the purchase of Light Railway No. 5 was decided against the company. The effect of the decision is that the company will receive £16,028 less than had the railway been purchased under the Light Railways Act, but the rent to be paid under the lease will be correspondingly reduced. Efforts are now being made to complete the sale, and to settle the terms of the lease. It is proposed to enter into an agreement with the Birmingham and Midland Company and the Shropshire, Worcestershire, and Staffordshire Electric Power Company to sell to the Power Company the generating stations at Hart's Hill, Amblecote, and Lye. As a condition of the sale of the generating stations, arrangements will be made for obtaining a supply of power from the Shropshire company at favourable prices. The arrangement for the management of all the tramways in the Black Country by the Joint Committee has continued to work satisfactorily, and the agreement with the other companies operating in the district has been continued for a further period. The following statistics are given in the report for the years 1907 and 1906 respectively:—Passengers carried, 8,305,052 and 8,432,544; average receipts per passenger, 1·32d. and 1·18d.; average working expenditure per passenger, 0·89d. and 0·78d.; proportion of expenses to receipts, 61 per cent. and 60 per cent. The meeting will be held in London to-day.

HAVANA ELECTRIC RAILWAY.—The report for 1907 states that the net earnings were $924,951, from which must be deducted fixed charges $558,877, leaving $366,074, and after paying dividends amounting to 5½ per cent. on the preferred shares there remains a surplus of $91,074. The earnings per car mile indicate that the maximum earnings upon the present track mileage is being approximated, and that additional mileage will soon be required to properly handle the increased traffic incident to the normal growth of the city. An application for extensions of route has been made.

ORIENTAL TELEPHONE & ELECTRIC.—The report for the year ended December 31st, 1907, shows that, including £1,036 brought forward from last account, and after deducting the interim dividends of 3 per cent., paid November 1st last on both the preference and ordinary shares, and making the necessary provision for redemption of the debenture stock of the company, the amount to be dealt with is £15,839. The directors recommend that this sum be appropriated as follows, viz.:—A final dividend of 3 per cent. (less income tax) for the year on the preference shares, £1,500; a final dividend of 5 per cent. (free of income tax) on the ordinary shares, making 8 per cent. for the year, £8,965; to reserve account, £3,500; carrying forward £1,873. The directors deeply regret to have to record the death on the 24th of last month of their esteemed chairman, Sir Auckland Colvin, K.C.S.I., K.C.M.G., &c., who occupied that position for ten years, rendering most valuable services to the company during that time. The directors issued in June last £50,000 4 per cent. redeemable debenture stock (part of an authorised issue of £200,000), partly for the requirements of the company's own exchanges, and partly to assist the subsidiary companies. The changes in the company's own systems by means of underground cabling have now been completed, but extensions to the scheme as originally laid out have become necessary. The increased business anticipated in last year's report, as a consequence of these important alterations, has made itself felt, and all the chief exchanges show an improvement for the year. At Rangoon, land had to be purchased for a new sub-exchange, which has since been constructed and is now in working order. In Mauritius, the Government has under consideration a scheme whereby it is hoped that the scope of the company's business will be extended to the whole of the island. The Indian local companies have declared the same dividends as for the year 1906, viz., the Bengal Telephone Co., Ltd., 5 per cent., and the Bombay Telephone Co., Ltd., 6 per cent., and the amounts have been included in the revenue account. The Telephone Co. of Egypt, Ltd., has declared a dividend of 10 per cent. for the year on both its preferred and deferred shares, which has also been brought into the account. That company is engaged on further extensions as well as on work connected with adapting the freehold premises they purchased in Cairo, in March, 1907, to the company's requirements. The telephone trunk lines between Cairo and Alexandria, and Cairo and Tantah, continue to be well patronised by the public and by that company's exchange subscribers. Installations of additional provincial telephone lines for the Government of H.H. the Khedive are still in progress, and it is anticipated that this branch of the company's business will take still further extensions. The Ministry of Public Works in Egypt granted to that company last year an authorisation for the installation of telephone lines in the province of Fayoum, in Upper Egypt, for a period of 35 years from December 17th, 1907; work in connection with it is now in progress. To provide the means to carry out these contracts, the directors have taken up a further 8,000 preferred shares of £5 each in the Telephone Co. of Egypt, Ltd. The China & Japan Telephone & Electric Co., Ltd., at Hongkong and Kowloon has also had a prosperous year subsequent to the reconstruction of their system, and propose to declare a first dividend shortly on their ordinary shares. The meeting will be held on the 29th inst.

PRIMITIVA GAS & ELECTRIC LIGHTING.—The report for 1907 states that the balance of revenue account and interest received from the German Transatlantic Electricity Company amounts to £105,348, to which has to be added £72 transfer fees, and £16,612 brought forward. After meeting interest on debentures, London expenses, directors' fees, interim dividends, and placing £6,221 to general reserve account, there is a balance of £33,881. A final dividend of 4s. 6d. per share, free of income tax, making 7 per cent. for the year, is recommended on the ordinary shares, leaving £15,881 to be carried forward.

SLOUGH & DATCHET ELECTRIC SUPPLY.—The report for 1907 shows a total capital expenditure of £44,886, the amount expended during the year being £1,494. The connections in 8-c.p. lamps equivalent amount to 13,072, and the number of units sold was 250,248, compared with 253,041 for the

Digitized by Google

previous year. The amount available for distribution is £2,756. After setting aside £750 for depreciation and £300 for directors' fees, a dividend of 3½ per cent., less tax, is recommended, and the balance carried forward. Mr. H. L. Prior, the Chairman, at the meeting last week, regretted that the balance-sheet was not so good as the directors would have wished. The Board were keeping a watchful eye on capital expenditure, and did not mean to supply any area unless they saw a prospect of a safe return. The net revenue account was not quite so satisfactory as that of the previous year, mainly owing to the high price of coal, which cost 4s. a ton more than during 1906, and the reason for the sale of current having gone down somewhat was the increasing use of Tantalum and Osram lamps. After some discussion, the report and accounts were adopted.

WINDSOR ELECTRICAL INSTALLATIONS.—The report for 1907 states that the number of lamps and motors installed now amounts to the equivalent of 42,171 eight c.p. lamps, of which 3,498 represent motors. The total capital expenditure now amounts to £83,954, an increase during the year of £1,427. Including £170 brought forward from last account, the net revenue account shows a balance of £4,929, to which has been added £250 from the dividend equalisation fund. Deducting debenture interest (£835), depreciation, renewals, and reserve fund (£1,000), dividend on 5 per cent. preference shares (£950), and directors' fees (£300), there is a balance of £2,094, out of which a dividend of 4 per cent., less tax, on the ordinary shares is recommended, carrying forward £194. At the meeting last week, when Sir William Shipley, the Chairman of the company, presided, the report and accounts were adopted. In his speech the Chairman referred to the effect upon the undertaking of the increasing use of metallic filament lamps, and said the Board was of opinion that these lamps would do for them what the incandescent mantle had done for the gas industry, viz., not only make electric light cheaper, but more popular.

WOLVERHAMPTON DISTRICT ELECTRIC TRAMWAYS.—The report for 1907 shows a total revenue of £25,125. After deducting debenture interest, repairs and maintenance, and providing £1,000 for the renewals fund, there remains a profit of £2,622. Adding the sum of £544 brought forward, there is an available balance of £3,166. The directors recommend that there be placed to depreciation and reserve fund £500, and after paying a dividend at the rate of 1½ per cent. per annum on the ordinary shares there remains to be carried forward £269. In view of the fact that £9,086 will be received from the Dudley Corporation as the purchase price of the tramways in Dudley, hereafter to be leased to the company, the directors have not thought it necessary to set aside any amount to sinking fund in this account. The capital outlay during the year amounted to £1,135, and was chiefly in respect of the equipment of rolling stock with the Lorain equipment to enable the through services into Wolverhampton to be effected. In connection with the tramways in Dudley the arbitration proceedings have now been completed and negotiations are taking place as to the terms of the lease to be granted by the Dudley Corporation. On the completion of the purchase £9,086 will be received from the Dudley Corporation as the price of this company's lines in Dudley. The company has joined the British Electrical Federation. The company has continued to benefit during the past year from the operation of its tramways as part of the system worked by the Birmingham and Midland Tramways Joint Committee. An agreement has been entered into with the other companies of the joint committee for providing a central car shed and repair shop at Tividale for the execution of repairs, &c., on the basis of each company paying a rent proportionate to the number of cars owned on January 1st, 1907. The parcels and goods traffic service has given satisfactory results during the past year, and there has been a considerable increase in the number of parcels handled. The following statistics are given in the report for the years 1907 and 1906 respectively:—Passengers carried, 4,381,837 and 4,102,374; average receipts per passenger, 1·36d. and 1·39d.; average working expenditure per passenger, 0·95d. and 0·89d.; proportion of expenses to receipts, 68 per cent. and 64 per cent. The meeting will be held to-day.

NEW COMPANY

CALMONT, KING & CO.—This company was registered on April 15th, with a capital of £3,000 in £1 shares, to carry on the business of electrical engineers, &c. The subscribers are:—M. Wolff, E. Browne, A. J. Mardlin, R. E. Jones, A. J. Winser, H. E. Patterson, R. Dickens. No initial public issue. The first directors are A. J. Mardlin, E. Browne, and M. Wolff (all permanent; special qualification, 300 shares).

PAMPHLET RECEIVED

ELECTRIC BLOWING EQUIPMENTS.—We have received a leaflet from Messrs. Veritys, Ltd., containing views of about 36 battleships, on board which their electrically-driven blowing equipments have been fitted.

MISCELLANEOUS CITY NOTES

THE LONDON ELECTROBUS CO.—We have seen an advance copy of a prospectus which is being issued by the London Electrobus Co. inviting subscription for new capital, divided into 240,000 ordinary shares of £1 each and 12,000 deferred shares of 5s. each. We have already given full particulars of the working of these omnibuses (ELECTRICAL ENGINEERING, Vol. II., page 903), and some of the figures in the prospectus as regards what has already been accomplished, and what may reasonably be expected when the number of omnibuses in service is increased, may be of interest. From the commencement of working in July, 1907, up to April 14th last, 970,271 passengers have been carried and 95,482 car miles run, and the average takings per mile have reached the excellent figure of 13·069 pence. A report by Sir Douglas Fox & Partners places the working expenses at 9½d. per car mile, including depreciation, when the proposed full number of vehicles are in operation, and the figures for the costs up to now fully bear this figure out, so that, if expectations are realised, there should be an ample margin of profit. The company now propose to place 150 "Electrobuses" on the streets, each running on the average 80 miles per day for 300 days per year. The whole success of electric omnibuses depends upon the capabilities and cost of upkeep of the accumulators, but some of the doubts which were felt on this score at the inception of the undertaking have been effectually dispelled by the fact that two well-known battery firms are maintaining the batteries and attending to the charging at an inclusive contract rate of 2d. per car mile.

COLOMBO ELECTRIC TRAMWAYS AND LIGHTING CO.—The directors recommend a dividend of 4 per cent., free of income-tax, for 1907, placing £5,111 to reserve and renewals fund. The sum of £13,000 has been taken from the reserve fund to write down the track renewals fund, and £1,000 to extinguish the mains and plant improvement account. The sum of £935 is carried forward.

RIO DE JANEIRO TRAMWAY LIGHT & POWER.—The *Financial News* states the Rio de Janeiro Tramway Light & Power Co., Ltd., has concluded arrangements with some leading banking houses in Paris and Brussels for placing £1,750,000 (one-half) of the issue of new five per cent. debentures, £400,000 of these debentures having been paid in full. A public issue of £900,000 will be made simultaneously in Paris and Brussels on May 12th, and the balance, £850,000, of the above amount reserved for Paris and Brussels, will be offered in the autumn.

TELEPHONE COMPANY OF EGYPT.—A further dividend of 6 per cent. upon the deferred shares, making 10 per cent. for the year, is recommended. The sum of £3,000 has been placed to reserve, and £10,433 carried forward.

APPOINTMENTS AND PERSONAL NOTES

Mr. Charles Burgess, of the Kirkcaldy Electric Tramways Department, has been appointed traffic manager for the Wigan Corporation Tramways. The salary is £200 per annum.

Mr. John J. Inniss has been on a business tour through China since last November. We understand Mr. Inniss has opened out a branch office in connection with his firm, Messrs. Inniss & Riddle, of Birmingham, at 40 Szechuen Road, Shanghai, where the firm will conduct their Chinese business as consulting electrical and mechanical engineers, machinery and general import merchants.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £59 10s. to £60 per ton. (Last week, £59 to £59 10s.)

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The statement of affairs of the bankruptcy of Messrs. Zobel & Sons, electrical engineers, of 153 Euston Road, London, N.W., show liabilities amounting to £1,990, of which £840 is in respect of trade creditors and the remainder in respect of cash claims. After allowing £60 for preferential claims the assets are expected to produce £627, leaving a deficiency of £1,656.

The liquidator in the winding-up of Messrs. D. Santoni & Co. (1906), Mr. R. G. Nordaby, having disposed of the business, requests all creditors against him as receiver to send particulars of their claims to 13-14 Abchurch Lane, London, by June 1st.

A meeting of the creditors in the bankruptcy of E. R. Smith, electrical engineer, 13A Heath Street, Hampstead, was held on the 16th inst., when a statement of affairs was presented which showed liabilities amounting to £1,516 5s. 11d., made up of the claims of trade creditors, £816 5s. 11d., and cash creditors, £500. The assets totalled £712 3s. 4d. After some discussion it was resolved to accept a composition of 10s. in the £ in cash. The chief creditors are Electrical Fittings Co. (£124), Armorduct Manufacturing Co. (£118), General Electric Co. (£84), and Edison & Swan United Electric Light Co., Ltd. (£60).

SUMMARY

The official nominations for filling the vacancies on the Council of the Institution of Electrical Engineers will be made this evening. Mr. W. M. Mordey will be proposed as President. Mr. C. P. Sparks and Frank Gill, the two who retire of the four Vice-Presidents, are proposed for re-election. As new ordinary members of Council, Mr. T. Mather, Major O'Meara, Prof. A. Schwartz, Mr. J. F. C. Snell, and Mr. G. G. Stoney are proposed in place of Messrs. Duddell, Judd, Mordey, Pearce, and Wordingham, and as Associate Member, Mr. J. E. Taylor, to succeed Mr. A. Campbell. We publish portraits and short biographies of the members nominated (Page 649.)

A new metallic filament lamp, made by the Stearn Electric Lamp Co., consists of a number of 20- to 25-volt tubular lamps grouped together on one holder to form a 100- or 200-volt unit. Each of the tubular lamps contains a substitutional resistance and a simple cutting-in device, so that if one of the tubes burns out the others are not extinguished. (Page 651.)

A new and conveniently arranged portable motor-generator for charging individual cells in large batteries has been put on the market. (Page 652.)

An entirely novel form of emergency brake has been introduced by Mr. P. J. Pringle, of Burton-on-Trent. A steel shoe or skid, shaped to enter the groove of the rail, is provided, which can be dropped in front of the car wheel, causing the wheel flange to mount the trailing end of the skid and so bring upon it the weight normally carried by the wheel. Tests have been made to show the great power of the apparatus. The brake is only intended for emergency stops, and as it cannot be applied gradually is somewhat violent in its action. (Page 653.)

Two fine examples of electric cranes are presented by a 10-ton double cantilever electric crane at one of the Lancashire and Yorkshire goods stations at Liverpool, and a 25-ton electric derrick crane at the North Wharf of the Clyde Navigation Trust at Renfrew. (Page 655.)

The discussion at the Institution of Electrical Engineers on Messrs. Handcock & Dykes' Paper on the effect of metallic filament lamps on the business of electricity supply, was resumed last Thursday. Mr. C. P. Sparks said that the standard of illumination would be raised, and he did not think the electricity supply business would suffer severely. He expressed disapproval of the maximum demand system and approval of the flat rate system of charging. Mr. C. H. Stearn exhibited the new lamps, referred to also in a separate article, and explained the system upon which

Digitized by Google

they worked. Mr. Percy Still preferred the flat rate of charging for lighting. Mr. Leonard Andrews cited instances in which the drop in revenue due to the introduction of metallic filament lamps had been considerable. He thought the flat rate of charging inequitable, and said that good results, both as to consumption and load factor, had been obtained some years ago by charging 10s. per lamp demanded and 1½d. per unit. Mr. J. F. C. Snell had found that comparing incandescent gas burners with metallic filament lamps, gas at 2s. 6d. for 1,000 c.ft. was, light for light, equivalent to electricity at 3½d. per unit. He believed in the flat rate of charging. Mr. Robert Hammond gave figures showing the increase in units generated in London during the past few years; he was convinced that the falling off in output would be only temporary, and that the new lamps would be a magnificent thing for the industry. He approved the principle of the authors' and Mr. Long's system of charging. Mr. E. T. Ruthven-Murray said that the power factor of auto-transformers used for metallic filament lamps was as low as 0·7 on low loads, but rose to nearly unity on full load. He gave interesting figures with regard to small consumers on a company under the control of the North Metropolitan Electric Power Co. He suggested the use of a time-limit indicator with a non-replaceable contact that could be set by the consumer. Mr. W. M. Mordey suggested the term "wire lamp" instead of metallic filament lamp, and spoke strongly against the maximum demand system. Mr. Frank Gill, Mr. Leon Gaster, and Mr. R. B. Matthews also spoke. Col. Crompton (the President), in summing up the discussion, took the view that the new lamps would seriously affect some of the supply undertakings, and that a review of the methods of charging was necessary. He regarded the Norwich system as the one which would ultimately be adopted. Written communications were sent by Mr. J. Horace Bowden, Mr. J. E. Tapper, Mr. C. E. Skelton, and Mr. W. R. Cooper. (Page 657.)

The thirteenth annual convention of the Incorporated Municipal Electrical Association will be held in Nottingham from June 30th to July 3rd. The business meeting will be held on the morning of July 2nd, and the annual dinner in the evening of the same day. (Page 662.)

In the discussion of the Paper read by Mr. G. Stevenson before the Glasgow Local Section of the Institution of Electrical Engineers, on the application of polyphase induction motors for industrial purposes, most of the speakers disagreed with the author's view that squirrel-cage motors in conjunction with friction clutches were superior to slip-ring motors. (Page 662.)

A special form of electrically-driven conveyor for dealing with fruit cargoes has been installed at New Orleans, as well as some travelling band conveyors for ordinary freight. (Page 663.)

The report and balance sheet of the British Westinghouse Electric and Manufacturing Co. for the year ended December 31st, 1907, shows trading profits amounting to £92,383, and after deducting interest on debenture stock and upon temporary loans, &c., there is a balance of £11,341 to be carried forward. (Page 664.)

The annual report of Marconi's Wireless Telegraph Co. for the year ended September 30th, 1907, has been issued, and contains some particulars of the company's transatlantic and maritime business, as well as the operation of the associated companies abroad. A large station is being constructed in Italy at Coltano, with a view to communication with South America. It is announced that Mr. H. Cuthbert Hall, on relinquishing his position as managing director and retiring from the board, has been allotted 10,000 fully paid shares as well as receiving a payment in cash. (Page 665)

The new 100-ton electric locomotives for the Detroit River Tunnel are equipped with four 300-h.p. interpole motors arranged on an articulated frame (Page 667.)

A new multiple circular slide rule for steam engine calculations has been designed by Mr. H. A. Golding. (Page 668.)

At the meeting of the Faraday Society, held on Tuesday, three Papers were read and discussed. The Paper by Prof. Huntington and Dr. Desch, upon the planimetric analysis of alloys and the structure of phosphor-copper, described a neat and rapid method for arriving at an idea of the constitution of alloys. T. E. Weston and H. R. Ellis described experiments upon the formation of aluminium carbide, and Prof. Piltschikoff contributed a Paper upon technical electrochemistry in Russia. These Papers are abstracted in Electrochemistry and Electrometallurgy. (Page 669.)

Under Electrical Science, in the British and American Section, is a note on some recent experiments on selenium cells. In the Continental Section a description of an electric hygroscope, by J. Pionchon, is given, and some researches by Mayer and Salles on the electric transportation of colloids are described. The proposal for a wireless hour device for determining longitudes is further discussed (Page 669.)

Mr. G. G. Stoney gave a lecture at the Royal Institution on Tuesday on the development of the Parsons turbine as applied to generating sets. (Page 670.)

A petrol electric railway car, which has recently been completed in America on the Strang system, is described. The principal feature of the system is the employment of a battery to supplement the power of the battery at times of heavy load. (Page 670.)

Amongst the patent specifications published last Thursday is one by the Parker Clark Electric Co. relating to a method of depositing a layer of pure silicon on a graphitised filament. The silicon, having a lower specific resistance, runs at a higher current density and temperature than the central core. Another by the British Thomson-Houston Co. describes a system of motor control by which a wide and uniformly graduated speed variation may be obtained with the use of two motors. The same company has a specification relating to flexible supports for the filaments of incandescent lamps. A patent by A. E. Kieth for an automatic telephone exchange expires during the current week. (Page 671.)

The estimated expenditure upon the Edinburgh Corporation electricity undertaking for the current financial year is £70,230, compared with £65,040 last year. The surplus is put at £11,408. The Postmaster-General has decided to use the telephone ducts in Edinburgh for the purpose of the underground telegraph line.—The Erith Council has objected to the plans of the London County Council, which fix the terminus of the tramway to Abbey Wood at a point 80 ft. distant from the Erith Council's tramways.—The Plymouth and Belfast Corporations have declined to take part in a conference proposed by the Halifax Corporation for formulating a mutual scheme with regard to third-party tramway risks.—For the year ended March 31st the Bury tramway accounts show a net profit of £4,606, against £5,225 last year, and upon the electricity undertaking there is a profit of £3,950, against £2,947. (Pages 673 and 674.)

The Birmingham Corporation has made an application to the Local Government Board for sanction to borrow £251,285 in respect of their electric supply undertaking. Local Government Board inquiries have been, or will shortly be, held as follows:—Brighouse (£3,600), Burnley (£26,460), Colne (£4,170), Ilford (£27,000). Loans have also been sanctioned as follows:—Walthamstow (£17,189 and £222) and Wednes-

Digitized by Google

bury (£8,000). The London County Council invite tenders for 2,000 tons, or alternatively 5,000 tons, of tramway rails and fastenings, and the Rawtenstall Corporation for steel tramway poles, overhead line equipment, &c. (Pages 674 to 676.)

At the annual meeting of the City of Birmingham Tramways Co. last week Mr. E. Garcke, the Chairman, in regard to a suggestion that the company should be placed in the hands of a liquidator, stated that no good purpose would be served by so doing, whilst they were able to earn more than 4 per cent. on their investments, merely for the purpose of redeeming the 4 per cent. debentures. The report of Messrs. Johnson & Phillips for 1907 shows a net profit of £42,981. The bulk of the revenue has been derived from their telegraph business. A dividend of 7 per cent. per annum upon the ordinary shares is declared, transferring £8,000 to reserve and carrying forward £6,873. At the meeting of the British Aluminium Co. on Friday the Chairman stated that the company had contracts for deliveries extending to 1910 upon the basis of current prices. (Pages 676 to 679.)

The new six-axle single-phase locomotive built by the Siemens-Schuckert Werke for the Seebach-Wettingen Railway is equipped with four 175 h.p. 15-volt series commutator motors of the same type as those in use on the electrified portion of the Midland Railway. (Page 679.)

The rapidity with which the metallic filament lamp has made its way and the enormous changes which it is already effecting in the electric lighting industry are remarkable. It is perhaps obvious that the first members of the general public to appreciate its advantages have been the large firms and business houses who are already electric light consumers. So great are the reductions that have been made in their lighting bills in some instances that a serious falling-off in revenue is actually feared by some people connected with the electricity supply industry We have already expressed the opinion that the effect in this direction will be far more than counterbalanced by the acquisition of new consumers attracted by the cheaper light. In this we have been supported by the majority of the speakers in the recent debate at the Institution of Electrical Engineers, the conclusion of which is fully reported in this issue. When any great advance is made in any industry it is seldom that one section will not suffer temporarily. The gain to the whole electrical world by the possibility of producing three times as much light as hitherto with the same consumption of electrical energy is almost immeasurable. Apart from the increased profit to the lamp makers, which they certainly fully deserve, the wiring contractors' business, which has recently been a bad one owing to over-competition, will receive an impetus that will once more put a premium on good and honest work, and the fittings industry will also be greatly benefited. In addition to this there will be indirect gains. An increased use of electricity for lighting will lead to its being more popularised, and the number of those who have learned its advantages for small power purposes will be largely added to. To some extent, therefore, the first loss to makers of electrical machinery by the present diminution in the growth of the central station load will be made good by an increase in the demand for motors. So far as the supply industry itself is concerned, street lighting should afford a means of rapidly making up for the decreased consumption of the large light users before the canvass of the small householders has had its full effect. By means of the new lamps miles upon miles of streets in all parts of the kingdom can be more efficiently and economically lighted than at present. Doubtless, there was much more to say on the subject of the effect of metallic filament lamps on the industry than there was time for during the two nights' debate at the institution in London. Dublin electrical engineers have also contributed their opinions, and the voice of Glasgow on the subject is to be heard next month. Yet there are still points upon which further facts and opinions will be welcome, and we are all ready for more information as to the lamps themselves. For this reason we trust that the Paper which Mr. Hugo Hirst has just sent in to the Institution will be discussed before the end of the session. Owing to the rapid strides that are being made it would be out of date if held over until next session by the Editing Committee of the Institution, but apart from this, few subjects of greater interest to electrical engineers could be found at the present time than the "wire lamp." The sugestion by Mr. Mordey that this name should be given to the metallic filament lamp is a good one, and we trust that the name will "catch on."

The question of whether a brake for pure "emergency" use should be added to tramcars working on hilly routes is likely to be revived by the success achieved by Mr. P. J. Pringle, of Burton-on-Trent, as the account of the tests published in this issue clearly proves. The provision of such a brake is in the nature of an accident insurance premium, as it is not available for service purposes. Mr. Pringle's brake is open to the general objection to such devices, viz., that when the emergency comes the motorman may forget the means provided to meet it, because its use calls for an effort of memory and intelligence at the moment when a man is least fitted to exercise them. The Pringle brake, however, appears to be better than previous devices, because it calls for no appreciable muscular exertion or complex action, and, as it retains a highly effective stopping power up to high speeds, there is greater time for the motorman to collect his wits soon enough to prevent a catastrophe or for the conductor to intervene with effect. To employ once more the insurance analogy, it is a premium paid to a sounder office, but one that is still not infallible. On a system with many severe gradients, it may be thought worth while to adopt this extra safeguard, but it does not in the least help to work the gradients, which must still be descended at low speeds, with the help of special hill brakes, by carefully trained men. We very highly appreciate the ingenuity by which Mr. Pringle has obtained a virtually higher coefficient of friction by the use of a wedge action, and it may perhaps be somewhat differently applied to produce a brake equally capable of use for service stops, hill coasting, or emergencies by graduated application, when it will have a far wider scope than in its present form.

Although the official nomination of candidates to fill the vacancies on the Council of the Institution of Electrical Engineers has been issued this year in time for members to put up alternative candidates, it is improbable that any advantage will be taken of the opportunity on this occasion. Mr. W. M. Mordey, who is proposed as President, is an old member who has

Digitized by Google

served the Institution well and faithfully on the Council during the last twenty years. We have in the past owed many lively and instructive debates to his initiative, and as President he will doubtless do much to maintain the standard of the discussions at the Institution meetings. To some extent perhaps it will be regretted that it was not possible to have a Manchester man as President this year in order to invest the forthcoming electrical exhibition in that city with more official prestige and importance; but it happens that there is no Manchester engineer on the list of those who have served as Vice-Presidents, and according to the Articles of Association no member is eligible for nomination as President unless he has previously been Vice-President. When Mr. C. P. SPARKS and Mr. FRANK GILL have served their third year in this capacity and retire, we trust that this omission will be rectified. Manchester is now probably the most important centre of the electrical industry, and it is not right that it should have but three representatives on the Council, one of whom is an *ex officio* Councillor, as Chairman of the Manchester Local Section, and another (Prof. SCHWARTZ) must be regarded as rather the representative of the professorial side than of the Manchester industrial group. Dr. E. HOPKINSON thus remains as the only representative of Manchester manufacturers for next session on the Council list just issued. It is also to be regretted that Mr. S. L. PEARCE, the Manchester City Electrical Engineer, should be on the list of retiring members. Of the new members and associate members of Council, two are telegraph engineers, two fill educational posts with conspicuous ability, one is a leading consulting electrical engineer, and one a manufacturer. No exception can be taken to any of the names; all are those of men who have shown distinction in their branch of the electrical profession. Yet the large proportion of the membership interested in the heavier side of electrical engineering must watch the Council list carefully, remembering that the professors and telegraph engineers are already well represented among the Past-Presidents who have five votes on the Council. It is to be understood that the proposal of alternative candidates to those nominated officially is now actually invited by the Council, and any class of electrical engineers who may think that their claims for representation are not adequately recognised in the selection of the official candidates, have an obvious course of action.

Telegraph Traffic.—In consequence of the interruption of the cable between Cadiz and Teneriffe, telegrams to and from Brazil, Argentine, Paraguay, and Uruguay will be sent via Brest-Dakar, without alteration of tariffs. The Via Fao route has been broken between Bagdad and Bassorah, and there is also an interruption between Bangkok and Saigon beyond Battambang. The blizzard in the United States has caused havoc among telegraph and telephone lines, and similar trouble was caused in Essex by the recent snowstorm. It is reported that the Spanish Government intend laying a new cable between Cadiz and Teneriffe. According to *Tropical America*, the Mexican Congress has voted appropriations for improving the telegraph and telephone lines already in existence, and for establishing a number of additional ones. The most important of the new lines will be two telephonic connections between Mexico City and the capital of the State of Hidalgo. A telegraph line will follow the northern border, another will put into communication the States of Hidalgo and Tamaulipas, while the cities of Jaltipan and San Juan Bantista in the south-east are also to be connected.

Wireless Telegraphy.—A letter has been received by the Liverpool Chamber of Commerce from the Colonial Office, stating that a suggestion to provide short-distance wireless telegraph stations between British Colonies is receiving attention.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, APRIL 30TH.

Royal Society.

4.30 p.m. Meeting at Burlington House, Piccadilly, London. Among the Papers down for reading is the following:—"On the Hysteresis Loss and other Properties of Iron Alloys under very small Magnetic Forces," by Prof. E. Wilson, V. H. Winson, and G. F. O'Dell, communicated by Sir William Preece, K.C.B., F.R.S.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at 25 Great George Street, Westminster, London, when Prof. S. P. Thompson, F.R.S., will deliver the first Kelvin Lecture on "The Life and Work of Lord Kelvin." At this meeting a bust of Benjamin Franklin will be presented to the Institution on behalf of the American Institute of Electrical Engineers, by Mr. H. F. Parshall, the British Local Honorary Secretary of that Institute.

FRIDAY, MAY 1ST.

Royal Institution.

9 p.m. Evening Discourse on "The Scientific Work of Lord Kelvin," by Prof. J. J. Larmor, F.R.S.

TUESDAY, MAY 5TH.

Royal Institution.

3 p.m. Afternoon Lecture II. by Mr. G. Stoney on "The Development of the Modern Turbine and Its Application."

THURSDAY, MAY 7TH.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at the Society of Arts, John Street, Adelphi. Paper to be read:—"The Manufacture of Electrical Condensers," by G. F. Mansbridge.

Röntgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London, W. Agenda:—Paper by Dr. Horace Manders on "Continuous Oscillations of Electricity and Their Application." Mr. R. S. Wright will show and explain the new "Vita" interrupter for obtaining an increased output from an induction coil without a corresponding increase of primary current.

FRIDAY, MAY 8TH.

Physical Society.

8 p.m. Meeting at the Royal College of Science, South Kensington. Mr. C. G. Whitehead will read a Paper on "An Examination of the Formulæ for the Grading of Cables."

Association of Engineers-in-Charge.

8 p.m. Annual Meeting at the St. Bride's Foundation Institute, Bride Lane, Fleet Street, E.C.

NEW PUBLICATION

"Journal of the Institution of Electrical Engineers, April, 1908." (London: E. & F. N. Spon, Ltd.) 5s.

Electrical Engineers' Volunteers.—Second-Lieutenant John L. Lewis has been promoted Lieutenant in the Severn Division.

Wireless Transmission of Photographs.—A demonstration of a system of transmitting photographs for press or police purposes by means of Hertzian waves, was given by the inventor, Mr. Hans Knudsen, at the Hotel Cecil, London, on Tuesday last. The photograph or sketch to be transmitted is prepared by giving the outline and shaded portions a rough surface. A metal point, which is given a reciprocating motion across the surface of the photograph, is agitated by the roughened surface, and is so connected to the trembler of an induction coil that Hertzian waves are given off by the transmitter whenever the point travels over a raised spot or surface. The receiver consists of a sensitive and quickly recovering coherer in circuit with a relay which causes another metal point to produce a series of marks on a lamp-black film on a glass plate, these marks corresponding in position with the roughened surface of the photograph. The metal point of the receiver has also a reciprocating motion, and runs synchronously with the transmitter, and after each cycle both transmitter and receiver points move slightly sideways. After each cycle the transmitter sends an extra series of waves, which operate a special coherer and relay. This latter starts the motion of the receiving point, and thus ensures that the two pieces of apparatus are working synchronously. A complete 5 × 4 in. photograph can be transmitted in about 15 minutes. By dusting the photographic negative before it is quite dry with a metallic powder, the dark raised portions of the gelatine film, being damp, retain the powder, and the necessary rough surface is produced. A sketch should be drawn with gum and the lines dusted with powder. In the present development of the system the pictures produced are wanting in sharpness of definition.

THE INSTITUTION COUNCIL ELECTION

THE Council of the Institution of Electrical Engineers consists of the President, four Vice-Presidents, fifteen ordinary Members, three Associate Members or Associates, and the Chairman of each Local Section for the time being, and the Honorary Treasurer, who are *ex-officio* Members of Council. All these Councillors are not elected annually. The President, two of the four Vice-Presidents, five ordinary Members of Council, and one Associate Member or Associate retire each year. Under the Articles of Association the President and Vice-Presidents are eligible for re-election, but may hold office three years in succession. It is customary, however, to elect a new President each session, selected from the list of those who have held office as Vice-President. The retiring Vice-Presidents, if not re-elected in the same capacity, are eligible as ordinary Members of Council, and any new Vice-President must have served previously on the Council as an ordinary Member. The ordinary and Associate Members of Council in most cases remain on the Council for three years in succession, which is the maximum under the Articles of Association, and then retire. This year the following Councillors are retiring:—Col. R. E. B. Crompton (*President*), Messrs. Frank Gill and C. P. Sparks (*Vice-Presidents*), Messrs. W. Duddell, Walter Judd, W. M. Mordey, S. L. Pearce, and C. H. Wordingham.

Mr. W. M. Mordey.

The Council will to-night nominate members to fill their places, but it is understood that alternative nominations are invited from the membership, both for the office of President and Vice-President, if desired, and also for ordinary and Associate Members of Council.

The Honorary Treasurer retires annually but is eligible for re-election each year, and Mr. Robert Hammond, who has filled this office since 1902, is nominated for re-election in the usual course.

The official nominations, which will be made by the Council to-night, will be as follows:—

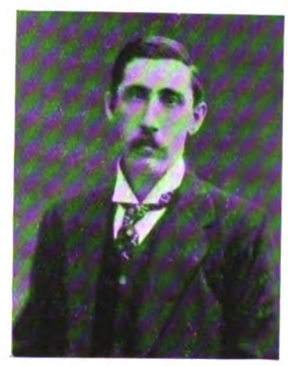
As President:
W. M. Mordey.

As Vice-Presidents:
C. P. Sparks and F. Gill.

[These are the two retiring Vice-Presidents, but as they have served only two years as Vice-Presidents, they are nominated for re-election.]

As Members of Council: T. Mather, F.R.S., Major W. A. J. O'Meara, C.M.G., Prof. Alfred Schwartz, J. F. C. Snell, and G. G. Stoney.

As Associate Member of Council: J. E. Taylor.



Mr. W. M. Mordey, whose portrait appears above, has been on the Council several times during the past twenty years, and has filled the office of Vice-President in 1904–5, 1905–5, and 1906–7. Prior to joining the Brush Electrical Engineering Co., in 1881, Mr. Mordey was in the Postal Telegraph Service, first in London, and then in Bradford. His first appointment with the Brush Co. was as Superintendent of the Testing Department, but he was later appointed Chief Electrician, in which capacity he continued until 1897, when he resigned and started in consulting practice. In 1900 Mr. R. A. Dawbarn joined him as partner. Mr. Mordey is a strong advocate of "one-phase" traction, and the Paper by himself and Mr. B. M. Jenkin before the Institution of Civil Engineers on this subject in 1902, which was awarded both the Telford and Stephenson Medals, is a complete exposition of the subject at that date. The following is a list of the Papers which Mr. Mordey has read before the Institution of Electrical Engineers:—"Some Prejudicial Actions in Dynamos" (1884); "Alternate-Current Working" (1889); "On Testing and Working Alternators" (1893); "A Detail in Parallel Working of Alternators" (1893), "Parallel Working with Reference to Long Lines" (1894); "Dynamoes" (1897); "Capacity in Alternate-Current Working" (1901). Mr. Mordey was awarded the Institution premium for his Paper on "Dynamoes."

Mr. C. P. Sparks, who, it is proposed, should serve a third year as Vice-President, has been on the Council during the years 1900–01, 1901–2, 1902–3, 1904–5, and 1905–6. Mr. Sparks was connected with Mr. Ferranti in his pioneer work from the very early days of electric lighting, and remained with the firm of Ferranti, Ltd., until 1899, when he became Engineer-in-Chief to the County of London Electric Supply Co., a position which he now holds. Mr. Sparks also practises as a consulting engineer, and has made a speciality of the application of electricity in mining work. He read a Paper before the Institution in 1906 on the "Electrical Equipment of the Aberdare Collieries of the Powell Duffryn Co."

Mr. C. P. Sparks.

Mr. Frank Gill, who has already served as Vice-President during the years 1905–7 and 1907–8, was also a Member of Council for the three preceding years. He is Engineer-in-Chief to the National Telephone Co. His successive appointments with the company have been as follows:—1890, Chief Electrician at Liverpool; 1893, District Manager for Blackburn and North-West Lancashire, and subsequently for Dublin and South Ireland; 1896, Superintending Engineer for Ireland; 1902, Engineer-in-Chief to the company. During his stay in Ireland, Mr. Gill read the two following Papers before the Local Section:—"Note on a Humming Telephone" (1901), and "Hydro-electric Phenomenon" (1902).

Mr. Frank Gill.

Digitized by Google

Major W. A. J. O'Meara, C.M.G., R.E., Engineer-in-Chief to the General Post Office, entered the Army in 1881, and was gazetted to the Royal Engineers in 1883. He went through the Burmah War of 1885, and after being on the sick list for nineteen months, returned to duty. In 1890, whilst with the Second Division of the Telegraph Battalion, Royal Engineers, he surveyed for, and constructed the trunk telephone line through Kent in connection with the London-Paris Telephone Service. Major O'Meara was in Kimberley on the outbreak of the South African War, after the relief of which he joined the Army Headquarters, and accompanied Lord Roberts into Bloemfontein. Later on he took charge of all municipal matters at Johannesburg on the British occupation being effected, when Mayor, Town Council, and Town Clerk were dispensed with. In 1902, Major O'Meara retired from the Army on being offered the position of Assistant Engineer-in-Chief at the General Post Office, conjointly with Mr. Roberts, on the retirement of Mr. Hookey, the then Engineer-in-Chief. In April last year, Major O'Meara was appointed to succeed Mr. (now Sir) John Gavey as Engineer-in-Chief.

Photo. Reinhold, Thiele & Co.

Major W. A. J. O'Meara, C.M.G.

Professor A. Schwartz is Professor of Electrical Engineering at the Manchester Municipal School of Technology. He has contributed three Papers to the Institution of Electrical Engineers, all more or less upon kindred subjects. The titles of these were "Fuse Phenomena" (1908), "Flexibles and the Testing of Rubber" (1907), and "Low-tension Thermal Cut-outs" (with Mr. W. H. N. James in 1905). His Paper on "Fuse Phenomena," read before the Institution this year, described some experiments carried out at the suggestion of the Sub-Committee of the Engineering Standards Committee, occupied with the standardisation of fuses. Before his appointment to the Professorship at the Manchester Municipal School of Technology, he was lecturer in Electrical Engineering at the South-Western Polytechnic, Chelsea.

Prof. A. Schwartz.

Mr. J. F. C. Snell is in practice as a Consulting Engineer, and has acted for the London County Council in connection with their Electric Power Bills, and also for the Home Office on the recent inquiry. He started electric lighting work as assistant engineer to Colonel (then Mr.) R. E. B. Crompton, at the Kensington Court station, and also in connection with the erection of the Notting Hill Co.'s station, and the Stockholm City Lighting. After three years with Mr. Crompton, he joined the late Major-General C. E. Webber as confidential assistant, being engaged on constructional, parliamentary, and general consulting work. Three years later he was appointed, in 1893, by Professor Henry Robinson to superintend the construction of the St. Pancras Vestry Electricity Works, and remained as Resident Engineer in 1895, when the works were started. From 1896 to 1906 he was Electrical Engineer to the Borough of Sunderland, and in 1899 he was, in addition, appointed Tramways Manager. He was President of the Incorporated Municipal Electrical Association in 1903, and Chairman of the Newcastle Local Section of the Institution of Electrical Engineers in 1901–2. In January of this year he read a Paper in London on "Cost of Electrical Power for Industrial Purposes" before the Institution.

Mr. J. F. C. Snell.

Mr. G. G. Stoney, who was Chairman of the Newcastle Local Section in 1903–4, has been connected with the firm of Messrs. C. A. Parsons & Co. for many years. He has devoted much time to investigations in connection with high-speed dynamos for use with turbines, and his Paper on this subject, read before the Institution on April 2nd, in conjunction with Mr. A. H. Law, set forth the practice of his firm in this respect.

Mr. G. Stoney.

Mr. T. Mather, F.R.S., comes on to the Council as a full member for the first time, but he was Associate Member of Council in 1904-5, 1905-6, and 1906-7. During his long association with Professor W. E. Ayrton, F.R.S., Mr. Mather has carried out a large amount of work in connection with electrical instruments, and he is the author of a very large number of Papers read before the Physical Society and other institutions on this subject. He at present holds the position of Chief Assistant in the Electrical Engineering Department at the Central Technical College, and Examiner in the Electric Lighting Department of Technology in the City and Guilds of London Institute. As co-author with Professor Ayrton, he read the following Papers before the Institution in 1894:—"A Universal Shunt Box for Galvanometers"; "Transparent Conducting Screens for Electric and other Apparatus"; "An Astatic Station Voltmeter."

Mr. J. E. Taylor is Assistant Superintending Engineer in the Postal Telegraph Department, London. He has undertaken considerable research work in connection with wireless telegraphy, and has been associated with the experiments which have been carried out by the Post Office Engineers-in-Chief. He was joint author with Mr. W. Duddell, F.R.S., of a Paper read before the Institution of Electrical Engineers in 1905, entitled "Wireless Telegraphy Measurements."

Mr. J. E. Taylor.

Alternative nominations must be made by two Members, supported by eight other Members, and must be sent in to the Secretary by Thursday next, together with the written consent of the nominee to accept office if elected. Ballot papers are then sent out to every Member, Associate Member, and Associate of the Institution. The method of conducting the ballot is not laid down in the Articles of Association, but it may be presumed that it would be a postal ballot. In the event of no alternative nominations being received by Thursday next, the Council's nominees will be declared duly elected at the Annual General Meeting on May 28th.

The Chairmen of the Local Sections, who are *ex-officio* Members of Council, have not all been elected yet. They are chosen by the Local Sections themselves. Mr. W. W. Lackie, Electrical Engineer to the Glasgow Corporation Electricity Department, has been selected for Glasgow, and Mr. H. E. Yerbury, Electrical Engineer to the Sheffield Corporation Tramways, has been elected Chairman of the Leeds Local Section.

The following Members remain on the Council:—

Vice-Presidents.—Colonel H. C. L. Holden, F.R.S., and Dr. G. Kapp.

Members of Council.—S. Evershed, H. E. Harrison, Dr. E. Hopkinson, J. W. Jacomb-Hood, J. E. Kingsbury, M. O'Gorman, G. W. Partridge, W. H. Patchell, W. Rutherford, A. A. C. Swinton.

Associate Members of Council.—J. Hunter Gray and H. Human.

THE NEW STEARN METALLIC FILAMENT LAMP

OUR readers will doubtless be glad to have a full description of the new metallic filament lamp which Mr. Stearn exhibited at the last meeting of the Institution of Electrical Engineers.

The principle is as follows:—The 100-volt Osram and similar metallic filament lamps consist usually of four metal filaments connected in series in one bulb: except in the case of the tantalum lamp the whole of the filament is not one continuous wire. These filaments are very fine—something in the order of one-thousandth of an inch diameter—and if there is a slight flaw in one of them, so that it burns out before its time, the whole lamp is rendered useless. Mr. Stearn conceived the idea of making up a lamp-unit consisting of four or five tubular lamps, each containing a single V-shaped filament and connected in series. Each of these tubular lamps requires from 25 to 20 volts, and is removable separately from the lamp body. The individual tubular lamps will cost about a shilling each, and, although the first cost of the whole unit with its body will be greater than an ordinary metallic filament lamp, Mr. Stearn estimates that the cost of renewals will be far less, as those filaments without flaws will burn far longer than the 750 hours, which is the present estimated life of the 100-volt lamps. Fig. 1 shows the 100-volt lamp unit, consisting of five 20-volt lamps, and Fig. 2 a 200-volt unit with ten lamps. In order to find out which lamp had burnt out in the original form designed, the porcelain body was provided with holes opposite each pair of contacts all round the circle of lamps, and the lamps could be short-circuited, each in turn by inserting a metal plug, until the broken filament was indicated by the group lighting up again. These holes are seen in the first two

FIG. 1.—A 100-VOLT LAMP UNIT. ABOUT TWO-THIRDS ACTUAL SIZE.

illustrations and in Fig. 4, which is a plan and section of the body with the cover removed. In Fig. 4, also, the spring contacts are seen which hold the lamp; the pins of the lamp pass through holes in the cover.

Although the same porcelain bodies are still used, there is an ingenious improvement in the lamp itself, made at the suggestion of Messrs. Handcock & Dykes.

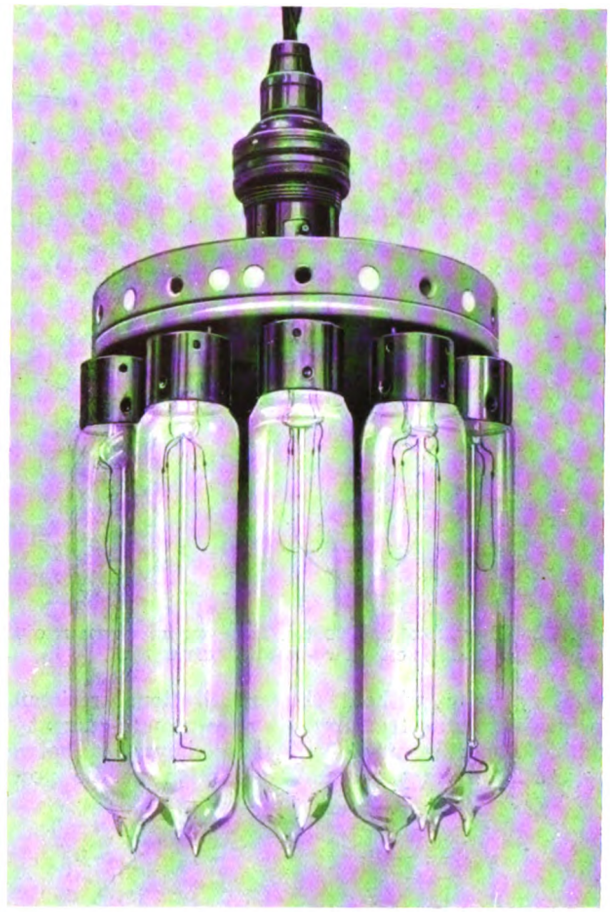

FIG. 2.—A 200-VOLT LAMP UNIT. SCALE ABOUT TWO-THIRDS ACTUAL SIZE.

By the automatic insertion of a substitutional resistance when any single lamp tube burns out, the remaining lamp tubes of the group are kept burning. This substitutional resistance is simply a short carbon filament within the lamp itself, clearly seen in Fig 3, in which the metallic filament is marked *M* and this carbon filament *C*. The carbon filament is connected in parallel with the metallic filament through a miniature spark gap contained in the lamp cap and consisting of two small pieces of metal, separated by two layers of an insulating material resembling tissue paper. The insulating material keeps the carbon filament out of circuit normally, but when any lamp tube burns out the potential across the spark gap rises from 20 or 25 volts to the full 100 or 200, the insulation is punctured, and the two pieces of metal are fused together, making a circuit through the carbon filament. This latter has the same resistance as the metal filament, so that the same current as before goes on flowing through the remaining lamp tubes.

Naturally, it is unnecessary with this arrangement for all the lamp tubes to be grouped together. The eight or ten 25- or 20-volt lamps on a 200-volt circuit can be distributed at various points in a room, or even in different rooms, and although they are on the same switch, the burning-out of one lamp will not cause the whole circuit to be extinguished. For this purpose the Stearn Electric Lamp Co., Ltd., of 47 Victoria

Digitized by Google

Street, London, S.W., who are the makers of these lamps, also supply 25-volt lamps with substitutional resistances in bulbs of the ordinary shape. The company are also now making in the factory near London 20- to 25-volt metallic filament lamps of 8, 12, and 16 c.p. (with the trade name "Leuconium") in

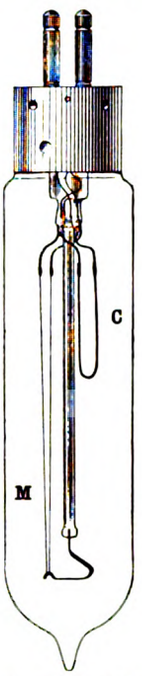

Fig. 3.—Elevation of Tubular Lamp with Substitutional Resistance. Two-thirds Actual Size.

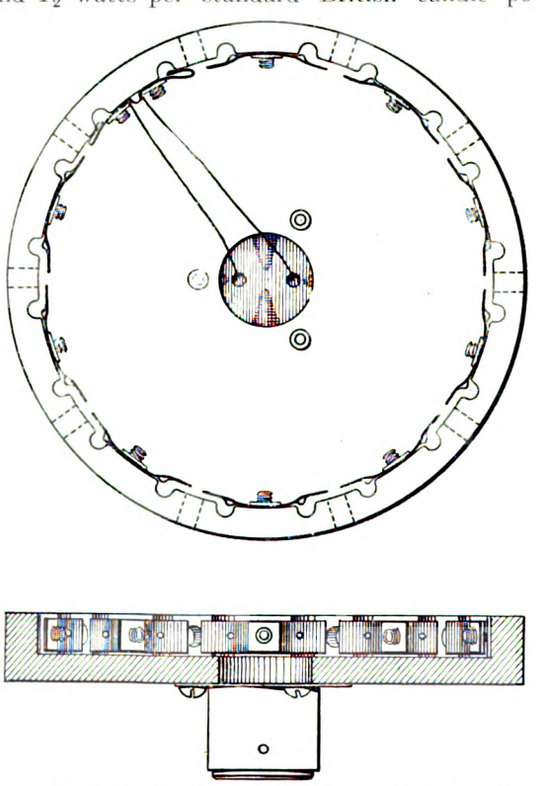
ordinary bulbs without the substitutional resistance, for use with auto-transformers on alternate-current circuits. The efficiency of all these lamps is between $1\frac{1}{4}$ and $1\frac{1}{2}$ watts per standard British candle power.



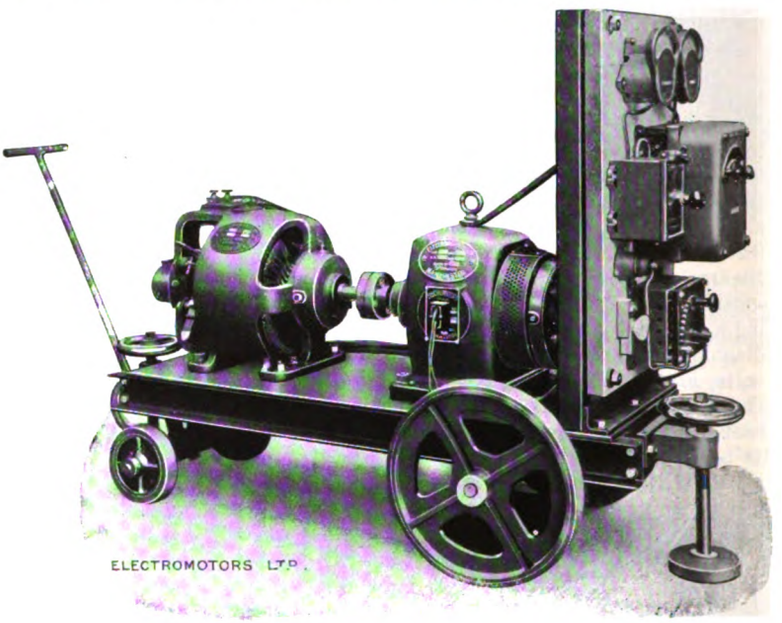


Fig. 4.—Plan and Section of Porcelain Body with Cover Removed. Two-thirds Actual Size.

The 20-volt tubular lamp gives about 10 c.p., and a group of ten on a 200-volt circuit will give 100 c.p. with a consumption of about 125 to 140 watts.

A PORTABLE CELL CHARGING SET

We illustrate herewith a new form of portable cell charger which has been manufactured by Electromotors, Ltd., of Openshaw, Manchester, for use in central stations for boosting up individual cells and similar purposes.

The set consists of a low-voltage dynamo, direct driven by an

Portable Motor-generator for Cell Charging.

ordinary semi-enclosed motor, suitable for the service of the station. Both motor and dynamo are mounted on a substantial wrought-iron truck, which is provided with front swivelling wheels, and with rubber tyres throughout. An anchoring arrangement is also provided to lock the set in any position that may be desired. At the back end, mounted on a substantial angle iron support, is a marble switchboard, carrying a suitable D.P. switch and fuses and starter for the motor, terminals, and a shunt regulator for the dynamo, capable of varying its voltage from 0 up to 6, a voltmeter, an ammeter, and a two-pin plug with flexible cable for plugging in at various points in the station. The set can be provided with two lengths of low-tension cable and special clamps for gripping on to any of the cell terminals. The whole arrangement is designed to occupy as little width as possible in order to enable it to pass between the rows of cells, and should be very convenient for attending to central station batteries.

Metropolitan Association of Electric Tramway Managers.—A meeting of this association was held at the Municipal and County Club, Whitehall, S.W., on Friday, April 24th, to receive and discuss the report of their Committee relating to the licensing of electric cars, &c. It was unanimously decidedly to press for a modification of such clauses of the Metropolitan Public Carriage Act, 1869, as were deemed necessary for present-day practice. The annual dinner of the association was held in the evening.

Coils of Bare Aluminium Wire.—The thin film of oxide which is always present on the surface of aluminium exposed to the atmosphere is of such high resistance that field coils are in use with no other insulation between adjacent turns but this film of oxide. Linen, paper, or other hygroscopic material about 0·1 to 0·4 mm. thick should be placed between the layers. In an article in a recent issue of the *Schweizerische Elektrotechnische Zeitschrift* it is stated that the insulation resistance and resistance to breakdown can be materially increased by immersing the finished coil for a few minutes in water or in an electrolytic bath of organic calcium salts. In the latter case the coil is made the positive, and a lead plate the negative, electrode. The coil is afterwards dried in an oven or by sending current through it until the temperature of the coil is about 120° C. The insulating film produced in this manner is said to have a dielectric strength of several hundred volts, and, further, it does not peel off the wire as do other metal oxides. So long as the coils are dried before being subjected to any high potential, the effect of moisture is, therefore, to increase the resistance to breakdown, and, consequently, coils of bare aluminium wire would seem to be particularly suitable for machines and other electrical apparatus working in damp places.

THE PRINGLE EMERGENCY TRAMWAY BRAKE

THE general question of tramway brakes has excited much attention and discussion during the last two or three years, while the special subject of emergency brakes to meet the conditions of runaways and collisions has called forth a good many suggestions from the ingenious, most of which are distinguished by their impracticability and ignorance of the controlling conditions. Among men operating tramways and other similar enterprises there is a rooted objection to "emergency" contrivances of any kind. Mr. P. J. Pringle, the Borough Electrical and Tramway Manager of Burton-on-Trent, takes the other view, as regards tramway runaways, thinking that a purely emergency brake is needed, and has applied himself to devising one which he believes to be free from most of the faults which attach to these devices. We need not discuss the general question here. From the following description and statement of the results obtained our readers will be able to judge of the efficiency of the brake, and of the probability of its powers being utilised when the very urgent need for them arises.

The illustrations herewith will give a good idea of the mechanical arrangements, and the method of operation, which may be assisted by the following description. The operative part of the brake consists of shoes, or skids of iron or steel, shaped below to the profile of the upper part of the rail groove, but less deep, and provided above with a flange and an inclined groove matching the wheel flange. These skids are hung close up to and just in front of the car wheels by a slotted link under pressure from compression springs, so that when free the skid drops into the rail groove, while the wheel flange mounts the trailing end of the skid and so brings upon it the weight normally carried by the wheel. The skid is held "off" by a wire cord passing to a lever on the platform, and is put "on" by a hand-lever which, on pressure, lifts a detent out of the first lever, freeing the skids. It is a special feature of the arrangement that a breakage of the wire, or accidental release of the lever, puts the brake "on," and also that the skid is brought into action by spring pressure and weight applied directly to it, whilst the effective braking pressure is applied by the mounting of the wheel and does not depend upon the driver's exertion either to put the brake on or to take it off. In other words, the braking pressure is taken from the kinetic energy of the car, by lifting so much of it as is on the braked wheels. As at present arranged on a four-wheel car, only the rear pair of wheels are braked, but the operating platform lever has two knobs, the forward one marked "Forward Braking" and the back one marked "Backward Braking," so that in the event of

a backward runaway the driver can brake the wheels which are then actually the rear wheels by direction of movement. Either pair can be braked from either platform, so that the conductor, or anyone on the rear

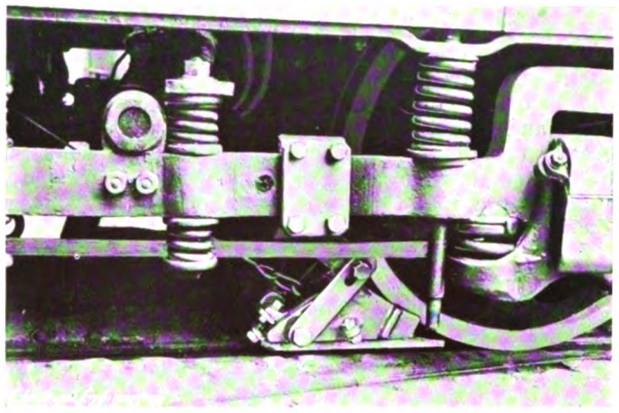

Fig. 4.—Brake dropped, but not engaged by Wheel.

platform of a runaway car, has the chance of using the emergency brake, whatever the mental or physical condition of the driver.

Apart from these details of rigging, it will be seen that Mr. Pringle's brake has two essential features. The first one, which we believe is quite novel, is that the skid or shoe enters the rail groove, and that the braking surfaces are on the sides of the groove and the skid, as the skid does not bottom in the groove; and the second, which has certainly been used to some extent previously in "run-back" skids, is that the braking pressure is got from the weight on a pair of wheels and not from any human or special mechanical store of power.

A considerable number of tests have been made in the presence of representatives of the Board of Trade, the technical Press, tramway men, and representatives of the Brakes' Committees of both Tramway Associations, with results of which some are tabulated below. The car used is a four-wheeled double-deck car, belonging to the Burton Corporation Tramway Department, of 3′ 6″ gauge, quite a normal car of the kind weighing probably between 9 and 10 tons unloaded. The tests were made on the Burton and Ashby Light Railway, on a straight gradient of about 1 in 12, in Hill Street, Swadlincote. Our representative witnessed a set of tests made with the rails wet and clean, the grooves running small rivers, the result of the snowstorm of the 23rd inst, and for comparison we print the results of a set taken on April 9th with rails dry and quite clean.

Tests made on April 9th, 1908. Rails dry and clean.

No	Speed in miles per hour at application.	Stopping distance in feet.	Stopping time in seconds.	Retardation in feet per second per second from stopping time.	Retardation in feet per second per second from stopping distance.	Remarks.
1	4½	3·75	0·8	8·22	5·8	
2	7	11·5	2·4	4·30	4·75	
3	10	28·0	not	taken	3·85	
4	10½	59·0	5·4	2·84	2·0	
5	10½	34·25	2·8	5·46	3·5	
6	10⅝	40·0	4·0	3·88	3·0	
7	12¾	32·5	3·6	5·18	5·3	
8	15	65·5	5·0	4·4	3·7	Wheels locked by rheostat brake.
9	18	66·0	5·8	4·6	5·3	Power kept on at full parallel.
10	18	84·0	5·2	5·0	4·1	
11	23	165·0	8·6	3·91	3·5	

Stop No. 8 was made after the wheels had been locked by a full application of the rheostatic brake. Stop No. 9 was made by the conductor, the power being left full on. These conditions represent contingencies which have led to certain runaway accidents.

On April 23rd with rails clean, but running with water, the following results were obtained:—

Tests made on April 23rd, 1908. Rails clean and wet.

No.	Speed in miles per hour at application.	Stopping distance in feet.	Stopping time in seconds.	Retardation in feet per second per second from stopping time.	Retardation in feet per second per second from stopping distance.	Remarks.
1	4¼	4·0	1·8	3·45	9·85	The shock on stopping made it very difficult to "clock" correctly on these stops.
2	7¼	14·0	3·0	3·5	3·96	
3	7⅞	13·9	2·8	4·0	4·6	
4	10½	23·5	2·6	5·9	5·0	
5	12½	38·0	3·4	5·37	4·4	
6	12⅞	68·5	6·8	2·73	2·53	One skid only used.
7	15½	62·0	4·4	5·15	4·1	Wheels locked by rheostatic brake.
8	15½	49·5	not	taken	5·15	
9	18¼	78·0	5·8	4·6	4·6	
10	21	153·0	9·4	3·26	3·07	Power kept on after skid dropped.
11	22	127·5	7·0	4·6	4·1	

In the above No. 6 was taken with only one skid in use, Nos. 7 and 8 were taken with wheels previously locked, and in No. 10 the power was kept on after the skid dropped.

The above results have been worked out for retardations deduced from both the observed stopping times and distances, and it will be seen that there is usually a difference between the results. As the speeds were taken from a tachometer driven off an axle, and the distances from chalk marks on the rails, the retardations deduced from the distances are the more reliable. This is especially the case at the lower speeds, when the shock at the application is much more violent than at the higher, and this makes correct timing of the very short intervals difficult. Otherwise discrepancies between the two sets of results show that the retardation is not uniform over the whole time, which is a natural result from the method of action of the brake. The figures show that a high-braking power is maintained up to speeds which would be uncontrollable runaway speeds with any form of brake acting only by the weight of the car upon the rail table, and suggest

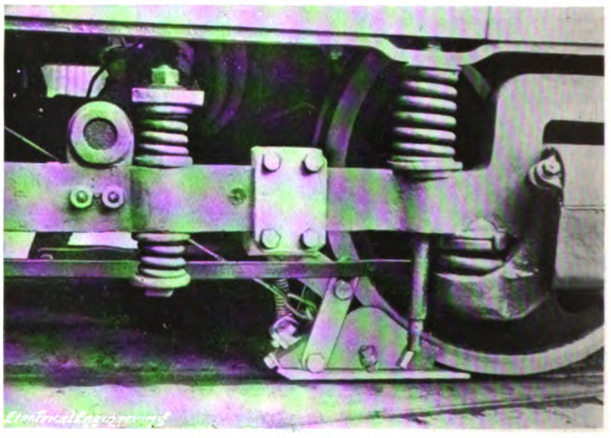

Fig. 5.—Brake in Action with Wheel mounted on Skid.

that for some reason or other the coefficient of friction between the sides of the groove and the skid is much higher, and does not fall off with speed so much as in the case of rail table, or wheel tyre, and an ordinary brake block. We believe that this would be a mistaken

Digitized by Google

view, but considerably more testing will be necessary to establish the facts.

What has been done in this form of brake, whether by accident or design, is to get a kind of leverage by wedging. The sides of the groove being slightly inclined to the vertical, the skid is forced into it as a wedge, and the pressure between the two bodies is the weight on the wheels multiplied by the ratio between the vertical and the horizontal projections of the grooves—in other words, by the inclination of the wedge. Thus, using only half the weight of the car, the effective braking pressure is several times that weight. Mr. Pringle merits much praise for attaining this result by whatever road he reached it. There is another point in the action which is well marked in stops from low speeds. These stops are very violent and the retardation very high, whilst at higher speeds there is much less violence. The reason seems to be that the first effect of the application is to make the car mount upon the skids at the expense of part of its kinetic energy. At low speeds the retardation corresponding to this loss of kinetic energy is greater than at high speeds; it is, in fact, roughly inversely proportional to the speed.

The retardation due to the mounting of the wheels on the skids is the predominant action at low speeds, whilst at higher speeds the frictional action is the more important. The retardations observed seem to agree with these views, and some portion of the discrepancies between the retardations as measured by the distance and by the time may be due to differing proportions of the two actions. The mounting occurs in a very short space of time, and may be somewhat dependent upon momentary conditions of cleanliness, dryness, &c. Besides the stop tests tabulated, several others were made simulating various accidental conditions, running backwards as from a failure of power when climbing the gradient of 1 in 12, and attempting to start against the brake, when the wheels slipped, but the car remained stationary. Under all the circumstances tried the brake held with complete security.

As above stated, the brake is put forward as a pure emergency brake, and not a service brake in any sense. It will not serve in place of the ordinary slipper brake for descending hills, nor for controlling cars in heavy traffic. The car has to be backed off the skids before the latter can be raised. This is in no way against the brake as to its designed use, and, granted that an emergency brake is desirable, then Mr. Pringle's is certainly effective, and adds little to the weight or bulk of the equipment. Further tests will be needed to show its action on greasy rails, but the very heavy pressure between the active surfaces and the scraping action of the nose of the skid should remove the offending mud instantly.

We understand that Mr. Pringle has made many experiments with various materials, and has settled on a particular grade of manganese steel as giving the best results. This is doubtless mainly a question of strength and hardness, as the skid is severely stressed, and is subject to abrasive action which will alter its shape and therefore its efficiency. A hard material is, therefore, necessary for the retention of regular action. If we are right about the action of the skid, bottoming in the groove would be fatal to its effectiveness.

We have to thank Mr. Pringle and his assistant, Mr. Hall, for the opportunity given us to see these interesting trials, and Mr. J. Toulmin, the manager of the Burton & Ashby Light Railways, and Mr. Shaw, of his staff, for the facilities and assistance offered us.

We understand that Messrs. Mountain & Gibson, Ltd., have taken up the manufacturing rights of this brake, so that it will, doubtless, be on the market within a short time.

TWO NEW ELECTRIC CRANES

THE accompanying illustrations represent two examples of somewhat different forms of large electric cranes which have recently been erected. The double cantilever crane shown in Fig. 1 has been erected by the Lancashire & Yorkshire Railway Co. at their North Mersey and Alexandra Dock Goods Station, Liverpool. It has a maximum lifting capacity of 10 tons over a span of 172 ft., whilst the track which the crane travels upon is 28 ft. centre to centre, and is 540 yards long, thus covering the greater portion of the company's immense timber yard and giving greater facilities to the traders.

The total length of the crane is 188 ft., and the total height 63 ft. It will stack timber to a height of 30 ft., the height to the under-side of the cantilevers being 43 ft. The operator travels with the crab, thus having the load always in view—a matter of importance when working amongst timber stacks; consequently all the

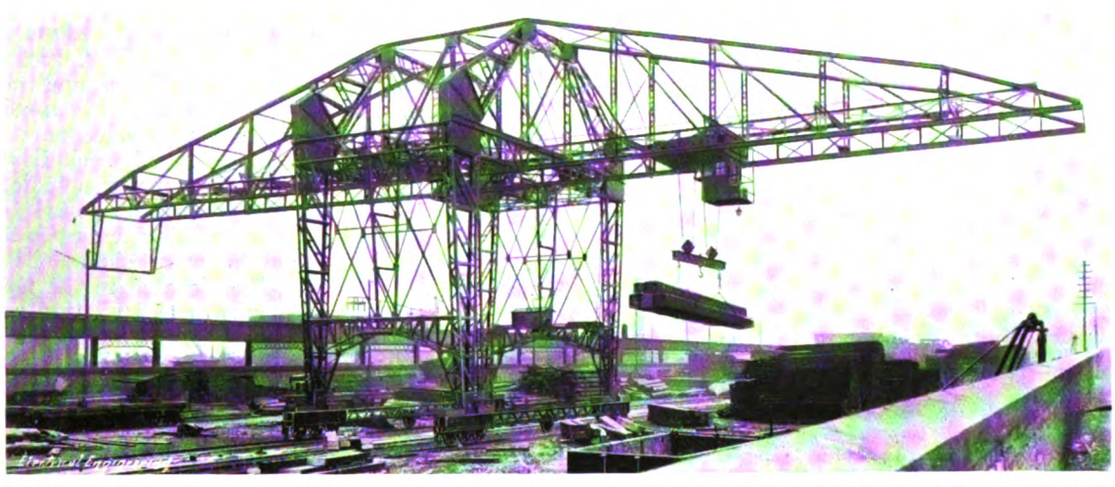

Fig. 1.—10-ton Double Cantilever Electric Crane, Lancashire and Yorkshire Railway, North Mersey and Alexandra Docks Goods Station, Liverpool.

Digitized by Google

controllers for working the motors are placed in the operator's cabin. The crane legs are placed sufficiently wide apart to allow a 40 ft. log of timber to pass through from one side of the yard to the other without requiring to be twisted. The supply of power, which is at 600-volt continuous current, is taken from the third rail of the Lancashire & Yorkshire Railway Co.'s Liverpool and Southport electric railway. The crane collects the current from an overhead wire with two tramway-type trolley arms and wheels, which are fixed to the end of one of the cantilevers. The crane is also well lighted with arc lamps placed out on the cantilevers, and lights are also fixed underneath the operator's cabin, so as to travel about with it.

The speed of operating, when dealing with the full working load on the hook, is as follows:—Hoisting, 10 tons at 93 ft. per minute, taking 93 E.H.P.; crab traverse, 10 tons at 482 ft. per minute, taking 19 E.H.P.; and crane traverse, 10 tons at 435 ft. per minute, taking 100 E.H.P. The crane has been tested with 12½ tons throughout its motions, and has a margin for stability at one end of the cantilever of 50 per cent., *i.e.*, equal to 15 tons on the crane hook. The total

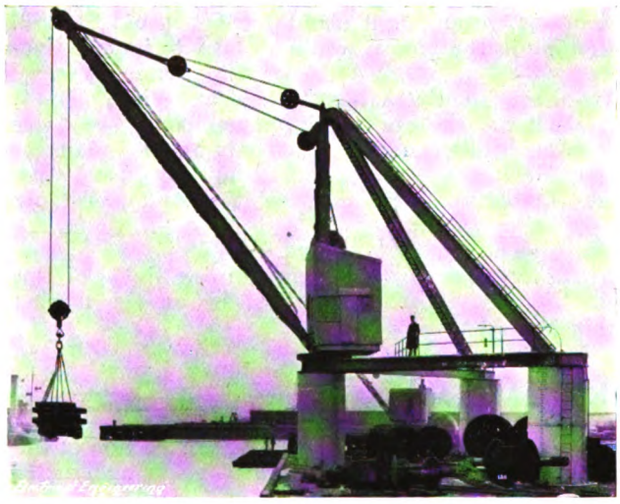

Fig. 2.—25-ton Electric Derrick Crane, Clyde Navigation, North Wharf, Renfrew.

weight of the crane, including the crab, is 160 tons. The crane has been made and erected by Messrs. C. & A. Musker, Ltd., Tue Brook, Liverpool, under the direction of Mr. George Hughes, Chief Mechanical Engineer of the Lancashire & Yorkshire Railway Company, to whom we are indebted for the photograph from which Fig. 1 is reproduced.

The 25-ton electric derrick crane illustrated in Fig. 2 has recently been erected by Messrs. Appleby's on the North Wharf at the Clyde Trust workshop, Renfrew. The crane is mounted on three circular steel-bound concrete pillars, so as to give 15 ft. headroom above level of the cope, and the foundations for these pillars are of concrete resting on piles. The crane derricks with full load from 20 ft. minimum to 45 ft. maximum radius. The lifting speed at 40 ft. radius with 25 tons is 12 ft. per minute, and with loads of 10 tons and under, 25 ft. per minute. The slewing speed with maximum load of 25 tons at 40 ft. radius is 245 ft. measured at snatch-block. The back stays are built up of steel plates and angles; the horizontal stays form a cross frame, where they join together and have large gusset plates top and bottom, the slewing spur-wheel and centre pin sole-plate being fitted on top.

The mast consists of two steel joists and braced laterally, and is supported on a live roller pathway 3 ft. 6 in. extreme diameter, and consisting of 16 forged case-hardened conical steel rollers 6 in. in diameter, working between roller path on sole-plate and path on mast-foot casting. The jib, 60 ft. between centres, is built up of steel plates and angles, the two sides being braced together laterally top and bottom by means of angles and gusset plates. The feet of the jib are fitted with cast-steel bosses, and the head is fitted with two 30 in. diameter cast-steel rope pulleys. The hoisting barrel is of cast-iron, 36 in. diameter, turned and grooved right and left hand to suit the hoisting rope, which is 3·89 in. circumference. The rope is fixed at each end of the barrel, passing from there over the jib-head pulleys, round the pulleys on the snatchblock to the jib head, the bight in the centre of the rope passing over a compensating pulley. Triple-spur reduction gear is provided, the main wheel and pinion being cast-steel shrouded gears. The other gears are cut from solid blanks, the spurs being of cast-steel, and the pinions cut from mild steel bars. In addition to the three reductions mentioned, a two-speed gear is coupled to motor drive, the ratio being 1·2. When lifting the full load of 25 tons, the slow speed is used, and gives a lifting speed of 12½ ft. per minute, but with the fast gear 10 tons may be hoisted at the rate of 25 ft. per minute. An automatic electro-magnetic brake is coupled direct to the motor, the brake drum being keyed to the motor spindle. This brake is applied by a weight immediately the current is cut off. In starting up the motor a solenoid coupled in series with it releases the brake. Combined with this is a centrifugal governor, which prevents the load, when lowering, attaining a higher speed than two and a half times the hoisting speed of the maximum load. A mechanical brake on the second motion shaft is applied automatically by the load and released by the motor. The motor is 30 B.H.P. running at 500 r.p.m., and is of the Westinghouse type. The derricking barrel is 36 in. diameter, and grooved right and left hand, and has main gears similar to hoisting barrel. Triple spur reduction is used here also, with automatic brake on the second motion, and operated from hoisting motor. This gear can be worked independently of the hoisting gear by means of clutches, and an additional hand brake is fitted on the second motion shaft for use when working at a fixed radius. When derricking, the hoisting or lowering gear is always in motion, an arrangement tending to keep the load level during the operation. The derricking gear is triple purchase, with six-part wire rope similar to the hoisting rope. The rope pulleys are 30 in. diameter, and a compensating pulley is provided to equalise the stress on the ropes. The slewing gear is driven through worm and spur-wheel gearing by a 10 B.H.P. motor. The worm is double threaded of forged steel, and the worm-wheel rim is of phosphor bronze with machine-cut teeth. Ball-thrust bearings are provided on the worm shaft. An automatic solenoid brake, similar to the hoisting brake, is fitted to the motor spindle. The slewing rack is of cast-steel, securely bolted to centre pin soleplate. An over-derricking device is fitted on the crane, and a radial indicator shows the slewing movement. The controllers, located in the machinery house, are fitted with a universal operating gear, and one lever only is necessary to work both. Change gear, clutches, &c., are operated by hand wheels placed conveniently close to the controllers, so that the crane-driver has every movement under control while watching the load. The machinery house is large enough to cover all the machinery except the derricking barrel, and is constructed of angle framing covered by corrugated sheeting, and is lined inside with wood boarding. Windows are fitted in three sides, and a sliding door at each end provides an entrance when the crane is in any position. A ladder up one of the pillars to a platform along one of the horizontal ties gives the means of approach to crane-house, and other ladders give easy access to all remaining parts.

Digitized by Google

THE EFFECT OF METALLIC FILAMENT LAMPS ON THE BUSINESS OF ELECTRIC SUPPLY

THE discussion on Messrs. Handcock & Dykes' Paper on "Electric Supply Prospects and Charges as Affected by Metallic Filament Lamps and Electric Heating" was concluded at the meeting of the Institution of Electrical Engineers on Thursday. In the Paper figures were given as to the reduction in consumption, especially when employing auto-transformers and 25-volt Osram lamps. The authors proposed to reduce the effect on the station revenue by the introduction of a new system of charging, by which the consumer would be charged a fixed sum per annum, depending on the maximum current he requisitioned on signing his contract, and a certain charge per unit in addition. They proposed the employment of a "limit indicator," which would dim the lamps when the contract maximum was exceeded.

We gave a long abstract of the Paper, together with a full report of the discussion, both in London and Dublin, in our issue for April 16th, p. 581.

Mr. Arthur Wright opened the first day's discussion by deprecating such advertisements as "70 per cent. discount on your bills," instead of "three times the light for the same bill." He pointed to the enormous increase in business which would accrue through cheaper light and to the necessity of reducing the cost of service connections. At present it cost nearly as much per kw. to connect a house as to build a station. Mr. Hugo Hirst announced a Paper on the evolution of the metallic filament lamp, which he had just sent in to the Institution. Incidentally he stated that new Osram lamps could now be paired with old. He thought there was no need to resort to the panic measures suggested by the authors. Mr. Bottomley Smith did not approve of the proposed "contract demand" system of charging. Mr. W. R. Rawlings, as an electrical contractor, objected strongly to the Wright system of charging, and favoured the authors' system. Mr. F. M. Long described a system in use at Norwich, in which the consumer is charged an annual sum of 12 per cent. of the net assessment of his house *plus* 1d. per unit.

Mr. C. P. Sparks (Chief Engineer, County of London Electric Supply Co.), who opened the resumed discussion last Thursday, said that as a supply company engineer he welcomed the metallic filament lamp as being the greatest step forward in the supply business for the last twenty years. The authors had suggested that these lamps, consuming as they did only a third of the energy that carbon filament lamps used, were going to be a great handicap to the supply business. He did not take such a pessimistic view for several reasons. In the first place, any new development, such as metallic filament lamps, was only taken up gradually; the whole of their consumers could not change from the carbon lamp to the metallic filament lamp in a day, and the supply station engineers therefore had a period in which to develop. The second advantage, in his opinion, was the question of the standard of lighting. If the public was going to remain content with the present standard of lighting, it was true that the demand for electrical energy might fall off, not, perhaps, in the ratio of a third, but in the ratio of half what it was at present, but when such a new development as the metallic filament lamp was put forward the whole standard of lighting was improved. Twenty-five years ago the introduction of electric light improved the standard of illumination, and a further improvement was brought about by the incandescent gas mantle. The gas companies, by the introduction of the mantle, received an enormous impetus and became real competitors of the electrical supply companies. Electrical engineers now had put into their hands a weapon that enabled them effectively to compete with the gas companies and still further to raise the standard of lighting. The gas companies had already possession of a very much larger field at the time the mantle was introduced, and in consequence the introduction of the mantle did affect them to some extent, and their progress was arrested. But in the case of electric lighting many had only scratched the ground, and they had now the larger field opened to them through the introduction of the metallic filament lamp. There was an enormous number of small consumers that it would pay them to connect. Another word he would like to say with regard to the standard of lighting, was that in his opinion people were willing to pay a certain amount for illumination. If a man had been paying from £3 to £4 for lighting, he would still continue to pay in the vicinity of that figure, and the standard of lighting would be raised. There might be a certain set back in the case of companies having a purely private lighting business, but companies and local authorities supplying large areas with mixed classes of business, public and private, would, he felt sure, find nothing but increased prosperity from the introduction of these lamps. On the question of tariffs, while he had the greatest possible appreciation for the educational value of the Papers read by Mr. Wright from time to time, he did feel that they all owed Mr. Wright a grudge for ever having invented the demand indicator. Unfortunately many electrical engineers used the demand indicator some years ago—it was a kind of fad—but now it had become almost extinct. The complications and difficulties when these indicators were used on a large scale, were so great that he thought one of the chief reasons of late years that business had gone ahead had been the simplification of tariffs. Another feature of the demand indicator was that the most important item of the bill was controlled by an instrument which was of a very inaccurate type and in no way compared with the accuracy of the meter which measured the quantity. He thought that the only method of charging which would find favour, on a large scale, with the public was the flat rate. A very ingenious system was mentioned at the last meeting, by which the tariff was to charge a fixed amount on the rateable value of the property and a low price per unit. That was a sort of tariff that might be applied in a small town by a local authority, but a company would not be able to do anything of that kind. People were already sufficiently worried by rates in the nature of fixed charges, and they did not require any more of them.

Mr. C. H. Stearn (Stearn Electric Lamp Co., Ltd.) said that the most satisfactory method of transition from carbon to metallic filament lamps on alternating-current circuits was by the use of transformers. In this way they could adapt the voltage to the lamp instead of the lamp to the voltage, which was a very much easier thing to do, but the problem with direct currents was a very much more difficult one. There was no other way of using metallic filaments except in series, whether they collected a number of filaments in one bulb or whether they placed them in separate enclosures, and then collected them on a common base, or whether they distributed the small units at a distance from one another and connected them in series. If they had to collect all the filaments in one place, it seemed to him that if they placed each filament in a separate enclosure and then assembled them on a common base, they had a very much more economical method for the maintenance of the lamps than in placing them all in one bulb. These filaments were extremely delicate, being, as compared with the carbon lamps, about one twenty-fifth of the section for the same candle-power and the same voltage, and on the average of three times the length. The average life of the lamp was therefore enormously increased by the fact that each element could be renewed independently of the others, instead of the whole set of filaments having to be replaced if there was a slight flaw in one and it burnt out. In a test he made, a group of five 20-volt tubular lamps was placed on a porcelain receptacle on an ordinary 100-volt circuit. At 600 hours one filament broke. In ordinary circumstances it would have meant a renewal of the whole lamp, but in this case that element could be renewed, and on this being done the lamp went on for 2,000 hours before another element broke. That was renewed, and at 2,600 hours a third broke. Assuming 5s. as the original cost of the lamp, with the three renewals at 1s. each, this meant 2,600 hours for 8s. instead of 5s. for 600 hours, which would have been the case for a single lamp, as the first lamp went at 600 hours. If, instead of assembling these units on one base, they were distributed, say, over an electrolier or in different parts of a room, then they had a more efficient system of lighting undoubtedly, but they had these two great disadvantages: (1) if one element went out all went out, and if all the elements were collected on an electrolier they might be left in total darkness at any moment; (2) it was necessary to make a search to find which one had failed, and the more there were in series the greater became this trouble. It had been suggested to him by the authors of the Paper, that, if it were possible to utilise the rise of potential that occurred when a filament breaks, to short-circuit the broken lamp, the trouble might be overcome. Several methods were suggested and some experiments were made, and finally they hit upon the arrangement which he exhibited. Mr. Stearn then explained the lamp which is described elsewhere in this issue, and illustrated its working by means of a model.

Mr. Percy Still (Chief Engineer, Chelsea Electricity Supply Co.) thought the authors' suggested system of charging was a satisfactory one from the point of view of providing an adequate return upon the capital invested in making provision for the supply to each individual consumer. The convenience which it might provide in doing away with the necessity of using more than one meter in the case of consumers who wished to use the energy for different purposes was, also, he thought, a great

Digitized by Google

point in its favour. In view of these and other advantages, it was, therefore, with great regret, after reading through the Paper, that he came to the conclusion that the system of charging was not practicable. It offered at least two very serious difficulties and objections. The arbitrary fixing of a contract demand by the electricity supply manager would be a difficult matter indeed, and he felt sure it would lead to constant and interminable discussion with the consumer. Whatever knowledge an electricity supply manager might think he had of his district, it was impossible to form an opinion from the number of lamps declared as to what proportion were likely to be generally used. The proportion would depend upon the particular habits of the consumer, upon the manner in which the installation had been wired, and upon whether it had been liberally lamped or sparingly lamped. The candle-power of the lamps, too, was a very uncertain quantity, because frequently the 8-c.p. lamps which were declared in the first place were subsequently altered to higher candle-power when the necessity arose. Also, the irregular use of heating apparatus, &c., would be another point which would add to the difficulties of fixing the contract demand. It was true that the authors proposed to use a limit indicator to get over these difficulties, but he felt sure that any such apparatus would not only be unsatisfactory in its working and expensive to maintain, but it would also lead to other serious difficulties with the consumer. A second objection which he could foresee to this system was that any system based upon a charge for contract demand, pre-supposed a fairly regular annual use of the supply by the customer. This might be workable in the case of shops and certain business premises, but in the case of private house lighting—certainly in the London residential districts—it would be an impossibility. Owners were frequently going away for long periods and at irregular times, they might sublet to a tenant with different habits, and many of the houses changed their ownerships fairly often in London. In the case of power supply to factories, of course, the case was very different, and a system based on a charge per kilowatt and a reasonable charge per unit, slightly in excess of cost price, might work very well, but for private house lighting he thought there was no doubt whatever that what the consumer wanted was a flat rate. The average consumer was not a mathematician, and he liked to be charged on the simplest possible system. But there was a very much better chance of doing business with a customer of that sort if he could be given a straightforward answer to his question as to what the price of the unit was, instead of having to go into an explanation of a complicated system of charging. In fact, this was the chief objection to the Wright maximum demand system. He did not agree with the statement in the Paper with regard to the "inherent absurdity" of differentiating between the charge for heating and lighting," but time would not permit him to pursue that point then.

Mr. L. Andrews (Key Engineering Co.) agreed that the metallic filament lamp was an excellent thing for all, and particularly for lamp-makers and wiring contractors, and ultimately for supply undertakings, but he did think there was something in the risk which the authors referred to. He read out a paragraph that appeared recently in Electrical Engineering (March 5th, page 368), in which it was reported that a certain Electricity Committee [Hastings] anticipated a deficiency of £3,581 for the year ending March 31st, 1908, and in their report the Committee stated that the reduced income from private lighting was almost entirely due to the lower consumption in consequence of the increased use of metallic filament lamps. It was interesting to note, he said, that the gross revenue of the undertaking was under £20.000 a year, and two years ago they made a profit on 15 months' working of between £2.200 and £2.300, so that there had been an annual falling off of about £5.000 in profits, which the Committee attributed to the metallic filament lamp. To this must be added the loss of the natural growth of the business, which growth for six consecutive years previously had averaged 18 per cent. per annum. This particular instance might be a special case, but he had discussed the matter with other central station engineers, and was told that in another town, whereas the normal increase was about 17 per cent., last year this was only about 4 per cent. These two cases showed that the remark made by Mr. Arthur Wright at the last meeting, that it depended a great deal upon the man and the way the problem was tackled, was true, and it also showed that the authors were somewhat justified in drawing attention to the matter. Coming to systems of charging, Mr. Andrews said that he considered a flat rate was very inequitable. For instance, it was impossible to sell current to a certain class of consumers at 5d. per unit and cover all charges, while, on the other hand, they knew it was quite possible, under certain conditions, to sell electricity at an inclusive rate of ¼d., and to make a good profit. The authors had referred to a system which was used at Hastings. This system charged 10s. per lamp demanded per annum, and 1½d. per unit. It worked remarkably well where the maximum demand system had been a failure, and he thought the reason was that every consumer understood it. Under the system at Hastings the output was increased in three years more rapidly than in the previous fifteen years, and the load factor was greatly improved; and, further, they found the system was being used intelligently. Consumers who previously used electric lighting in windows only, had basements wired, and used them during the day, thus improving their own load factor and also that of the supply authority. Incidentally the advantage of this system was that it would have made it possible to get over the loss referred to above by offering the consumer a reduced rental per lamp of maximum demand, and increasing the charge made on the alternative flat rate.

Mr. J. F. C. Snell said he took a more optimistic view of the advent of the metallic filament lamp than the authors. Some time ago he made some photometric tests of incandescent gas burners, and found that 11 c.p. hours per cubic feet were obtained with gas at 2s. 6d. per thousand. That meant that the cost was 0·003d. per c.p. hour. With a one watt per candle-power metallic filament lamp, that meant it was equivalent to electricity at 3½d. per unit, a figure at which a great many stations were supplying current for lighting, and a figure which he thought most undertakings would reach. He could not help feeling that the use of auto-transformers and the fixing of lamps in series was a temporary expedient, and that the inventive genius of the lamp manufacturer would produce a lamp which would work singly on the 240-volt circuit. In the Paper the authors referred to the capital invested in gas and electricity undertakings. Reading these figures, he thought they took a very pessimistic view of the electrical industry. For instance, the capital outlay on electricity undertakings was £7 10s., and on gas £4 10s., to obtain a gross revenue of £1 per annum; whilst the ratio of working expenses to receipts was 46·3 per cent. and 75 per cent. respectively. But the authors did not point out that the net profit on the gas undertakings was only an average of 5·44 per cent., whereas in the case of electricity undertakings the average was 6·89 per cent. Of course, it might be said that this was due to the charges for electricity being too high; but he did not think this was really the case. If the gas undertakings were in the position of the majority of electrical undertakings, and had to pay in addition to interest, sinking fund charges, amounting in all to 6½ per cent., they could not do it because they would require £8.000.000 to pay 6½ per cent. on the capital sum, whereas the profit was only £6.800.000. In the case of electricity, on the other hand, they required £2.250.000, and they had £3.275.000 with which to do it; so that the electricity undertakings appeared to be in a very much better position in that respect than gas undertakings. Continuing, Mr. Snell said that he was one of the heathens who differed from Mr. Andrews and the authors, and believed in the flat rate; although it was not scientifically the correct way, it was commercially the best way of charging lighting consumers. He had had some years' experience in the provinces in a town where gas was extremely cheap, and he knew the very great difficulty he had, in the first case, with the maximum demand indicator. Like many other engineers, he followed that craze, and he also adopted other methods, but finally he adopted a simple flat-rate method, and he could not help thinking that as the supply became more general they would be in a better position to charge a uniform flat rate initially, with varying discounts according to the user.

Mr. Robert Hammond was thoroughly with those who believed that the new lamps were a magnificent thing for the industry. They had been saying for the past twenty or more years that they could entirely abolish gas if, by various methods of economy, electricity could be produced cheaply enough. They had made a fair fight against gas for all these years, and at last they found themselves in possession of the metallic filament lamp, and of being able to supply in England electricity at practically a cheaper price than that at which gas was being supplied. Of course, they were all well acquainted with the fact that in many foreign cities gas had been entirely abolished. When he first went to Madrid to lay down the electricity works there, gas was 12s. per thousand, and even with carbon filament lamps they were able to make such a show that the gasworks were shut up. They had talked of shutting up the gasworks in England for a great many years, and the invention of the metallic filament lamp made the tenure of the gas manager a very short one. He was not so sanguine as Mr. Sparks that they were going to raise the standard of lighting. He thought that in most electrically-lighted houses there was too much light. As long as the Gas Light & Coke Co. was paying its big dividends he was very happy, because he saw what an enormous field there was for electricity. When Mr. Cripps last year was before the Parliamentary Committee, he stated that his clients, the Gas Light & Coke Co., were actually drawing one million pounds per annum from their penny-in-the-slot meters; he (Mr. Hammond) immediately stated in his evidence what a striking proof this was of the enormous advantages that were coming to the electric lighting companies when they took in hand the supply to small consumers. The falling off of output was, of course, going to happen in many cases through the introduction of metallic filament lamps, but it would only be temporary. He had provided an extra 1,500 kw. set at Hackney fifteen months ago; the plans were laid down for it in order that it might be working in December to cope with the enormous increased

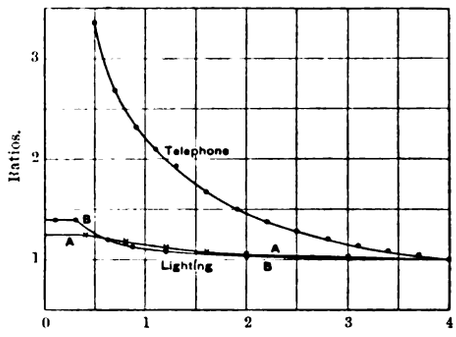
* The word "absurdity" in the Paper was altered to "difficulty" in the author's revised proof.—Ed. *E. E.*

Digitized by Google

load. As a matter of fact, that load had not come on; they were only about 100 kw. ahead instead of 600 or 700 kw., as had been anticipated. London had not suffered very much so far, however. In 1901 the number of units turned out in London was 69,000,000, an increase of 34 per cent. over the previous year. In 1902 the amount was 86,000,000, an increase of 23 per cent.; in 1903, the number was 110,000,000, an increase of 27 per cent.; 1904, 129,000,000, an increase of 17 per cent.; 1905, 154,000,000, an increase of 19 per cent.; for 1906 there was an increase of 13 per cent.; and for last year to March 31st the increase was 12 per cent.; so that London was not doing badly. He felt quite confident that by the time metallic filament lamps were well at work immense good would come from them. He was entirely with the authors in ridiculing the idea of charging heating and lighting at different rates. He quite understood a factory having its power at a different rate in consequence, of course, of the immense load factor, but he could not understand a double meter system in private houses. He thought a great deal of good would come through the wiping away of that idea, and putting the whole of domestic demand on one price. He was confident that the principle of the author's proposed system of charging was sound.

In some remarks subsequently communicated, Mr. Hammond says that he entirely dissents from those who hold the opinion that the class of consumer who uses the light the longest number of hours can be best obtained by a flat rate. He continues: My strong opinion is that Messrs. Handcock & Dykes are working on the right lines, and that their proposed contract demand system is one which would abolish many of the unpleasantnesses connected with the Wright maximum demand system. I see, however, some objection to a system which might entail a constant source of anxiety upon the consumer, and I welcome Mr. Long's bright idea that each consumer should be charged a rental based upon the assessment value of his house, and, in addition, a small running charge. I trust that the outcome of this debate will be a determined attempt on the part of the leaders of the industry to get the Board of Trade to insert into their next Electricity Bill a provision enabling the electricity supply undertakings throughout the kingdom to make a fixed charge, whether by means of a "rate per kilowatt of maximum demand," or by a proportion of the assessment of the premises. With regard to the "fixed rate per kilowatt of maximum demand," this has figured in all the recent Power Acts and Bills, and is included in the three Bills of this Session.

Mr. Leon Gaster said that if it could be arranged that a maximum demand consumer would not be charged more than a flat rate consumer, he thought the maximum demand system was going to be a great help to the central station. He thoroughly agreed that the metallic filament lamp was going to bring about a great advance in the electrical industry, but hitherto the consumer had not been educated to a judicious use of his lamps. Contractors and lamp makers did not care twopence about the consumer. He suggested the engagement of educated canvassers, men who not only looked nice, but who knew what they were talking about. The gas companies' reply to the electrical people on the question of profits was, that the electrical profits were paper ones; gas people had a safe.



Mr. K. A. Scott Moncrieff (Chief Engineer to the Electric Supply Corporation) said that the cost of services had been much reduced of late, and there was still further scope for reduction. Another point in this connection was that, as the number of services were increased, the cost of the distributing mains per kw. connected was reduced, and this was a very important matter. He thought it would be found that where the supply was cheap the cost of mains was low. There were large batches of houses with rents of £30 and £35 per annum where there was a great scope for business of a paying nature. It was a matter of regret to him that the authors had not given some description of the apparatus which they proposed for dealing with the contract demand. The matter had been brought to his notice some months ago, when he saw an advertisement of an American apparatus of this nature, but after thinking over it very carefully he decided he would not be the pioneer in introducing it. The authors' proposal resolved itself into practically a heavy meter rent and a low charge for electricity. It would be possible to devise a meter which, when it ran at the maximum rated output, would either read at double speed or switch on another train of wheels charging 8d. per unit. It appeared that the change over to metallic filament lamps would be gradual; it would probably take five years for the thing to settle down, and in that time a good deal might happen. When reading the Paper he happened to have before him an ordinary load curve, and it occurred to him to apply the reduction to the load curve. The result was that he cut off the peak, and he got the best curve he had ever seen from the generating point of view, but he had also cut off all the profits. The day load on the curve was motors. He did not think they realised the vast progress that had been made in motor loads, particularly in the north country. In looking through some figures recently he hit upon Darlington, where 38 per cent. of the output was on the tramways, 38 per cent. for lighting, and the remaining 24 per cent. was motor load. In the five years in which he suggested that the metallic filament lamp would establish itself, the motor load was not going to stand still. In addition to that, lighting by metallic filament lamps would reach further, and would obtain a much better diversity than at present. They should hope to light a man from the time he got up in the morning until he went to bed at night. Very few of the supply people did that now. A man might have electric light for an hour or two in his office, and then he went home to gas, or it might be *vice versâ*. In this way there was a great field for extending the use of electric light, making it so cheap that people would waste it and bring down the obnoxious peak in the curve, and they might even hope to get a very much better load factor. Lighting would then be an incident in the diversity of the load; it would not be the predominant partner, and they would reach a point when devices for giving a different rate for lighting and power would be unnecessary, and they could offer a rate for domestic lighting low enough to get domestic heating also.

Mr. E. T. Ruthven Murray (Chief Engineer, North Metropolitan Electric Power Supply Co.) said he would have liked to have heard particulars of tests on small transformers, which he regarded as an entirely temporary expedient. He had heard an alarmist rumour that the power factor was not more than 50 per cent.; but he had found, from some tests of his own, that this was not so. Although at low loads the power factor might be as low as 0·7, it got up to nearly unity at full load. The authors referred to small consumers, and suggested that these had not been tackled satisfactorily by the supply undertakings. One place supplied by a company under the control of the North Metropolitan Power Co. had more lamps connected per inhabitant than any other place he knew of. No less than 25 per cent. of the consumers were rental-wired or "free" wired, and the revenue upon the capital outlay was 12½ per cent. He thought that if it was possible to get this percentage return, including everything, upon free-wired and rental-wired consumers, it was quite a satisfactory business to go into. The absolutely free-wired installation was a most excellent thing in small towns. There was a very large consumption per 8-c.p. lamp installed, for, of course, the lamps were only put in where they were used for long hours; the annual consumption per 8-c.p. lamp in some of these installations was as high as 20 units. In his opinion the reason why the maximum demand system had given so much trouble in many districts was because the wiring contractors had not taken the trouble to understand it. The authors in the Paper mentioned that Section 19 of the Electric Lighting Act of 1882 provides that every person shall be entitled to a supply of electricity on the same terms on which any other company or person is entitled under similar circumstances to a corresponding supply, and stated that they did not understand why a consumer should pay one price for lighting and another for power. Perhaps the authors were not aware that in a large number of Provisional Orders now, the fourth schedule prescribed one rate for lighting, perhaps 7d and 2d., and for power and all other purposes another rate, probably 2½d. Mr. Andrews had already referred to the system in which a fixed charge of 10s. per lamp was made. It was an interesting fact that if the maximum demand indicators were calibrated in thirtieths of a kilowatt, at the declared pressure, that was equivalent to an 8-c.p. lamp taking 33⅓ watts. With a system in which the fixed charge was high, and the charge for energy was low, there was an enormous advertising value. In an undertaking with over 2,000 consumers, with which he was connected, he fixed the charge at 1s. 9d. per 8-c.p. lamp per quarter, and 1d. per unit. The advertising value was so enormous that even the *Daily Mail* was "had" by it, and published a paragraph saying that the Willesden Council was supplying electricity at 1d. per unit; they forgot all about the 1s. 9d. per quarter. That 1s. 9d. represented £10 10s. per kw. per annum. With regard to the contract demand system, he agreed with one of the previous speakers that they would have a burdensome life if they had to fix the contract demand for every consumer. The easiest way of dealing with the limit indicator would be to have a contact which the consumer himself could adjust, to decide what the maximum demand was going to be; it could then be arranged for a bell to ring to give him warning when this was exceeded. He thought this would meet the difficulty. He absolutely failed to understand the authors' opinion that their system of charging would enable heating and such like to come into general use, for he could not see where the advantage came in for the consumer. If a consumer put a radiator or kettle on, it was going to increase his maximum, whether he was on the contract demand system or on the ordinary maximum demand system. His idea was to put an attachment by which the consumer could indicate his maximum demand and which could not be pushed back—and let that be the instrument on which the demand was fixed.

Mr. F. Gill (Chief Engineer, National Telephone Co.) exhibited the curve on page 660, in which he had taken three cases: Wimbledon and Birmingham for electric lighting, and the third curve represented the charge for telephone calls. Ordinates marked "ratios" are the ratios between the price charged and the number of units or telephone calls respectively, taking the rate at 4,000 calls or units as one in each case. *B* represented Birmingham; it started at 5d., and came down to 3·61 per unit when 4,000 units were consumed. The Wimbledon case began at 4¾d., and came down to 3·65d. According to the authors, if there were a large reduction in the consumption the increase

Digitized by Google

of price per unit was so little that the undertaking might lose considerably. In connection with telephones, they had a sliding scale, with more slide, so to speak. The telephone scale, of course, only did to some extent what the maximum demand

system did, but he thought it did it in a simpler way. It took into consideration the standing charges, and then the lower subsequent cost of giving the service after it had been established. Incidentally, he mentioned that when he was looking into this question he had a little difficulty in finding anybody's rates. One electric lighting engineer in London said everybody had something different, and it all depended on the look of the consumer.

Mr. R. B. Matthews said that the introduction of the metallic filament lamp would only have a temporary deleterious effect upon the profits of electric lighting stations, and in the end was bound to do a great deal of good. He advocated a scheme of "persistent educational publicity," which would take a year to get into proper working order, and from which benefits would be derived in the second year. The cost of services was coming down rapidly at the present moment. In one district in London last year the average cost of the services was just £4. There was a slot meter on the market at 30s., and for ordinary house services there was an ordinary meter at £2. Consumers could not understand the Wright maximum demand system, and those who had attempted to understand it did not use as much current as they might otherwise.

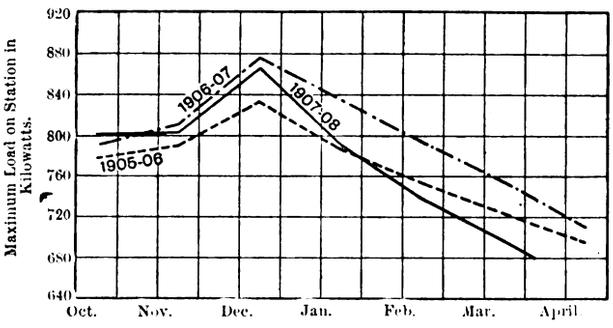
Mr. W. M. Mordey said he wished to make a small suggestion in the direction of simplicity of words, and it was that they should call these metallic filament lamps "wire" lamps. They really had no business with the word "filament" in connection with lamps; it was a term introduced by the patent agents and lawyers over a patent case when they had to determine what was a filament and what was a stick. It was imported by the physiologists and botanists, and he thought it was far better to simplify the name of the lamp and call it what it was—a wire lamp—a good old single-syllable Anglo-Saxon word. He was with those who thought that this wire lamp was going to be a very great thing indeed for the electrical industry. There might be a little dip in the curve, but the curve must go up very much more rapidly when people realised what they had really got. He would like to emphasise Mr. Arthur Wright's advice which he gave at the last meeting, viz., to imitate the broad lines of the gas companies, and do away with self-imposed restrictions. That advice on the part of Mr. Wright was the best he had ever given, and, coming from Mr. Wright, very great weight must be attached to it. It might be that Mr. Wright was seeing that the maximum-demand system was not theoretically right at all. There were a good many misunderstandings with regard to it, and the fact that it was not applied for power purposes was an indication that it was not believed in. With regard to the point raised by Mr. Long as to short-circuiting the demand indicator when a man gave a party, he quite agreed with Mr. Long that when one man gave a party his guests shut up their houses to a sufficient extent to keep the demand on the station unaffected. In 1901 there were three demand stations to one flat-rate station. He now found that the exact reverse was the position, viz., one demand station to three flat-rate stations. But there was an intermediate class which gave both systems optionally, and the proportions were three optional, three flat, and one demand, showing that there had been a great change of opinion on this subject. The load factor was not any better; in fact, it was worse in the demand stations; the units sold per lamp were not improved; and the price of the unit was not improved either. The system did not do any of the things it was supposed to, but it swallowed up in capital charges enough to cover a good profit for two or three years. It might be interesting if he gave some results which he had got out illustrating what had happened since 1901, when Mr. Wright read his Paper on the maximum-demand system. The output had gone up fourfold, and the average price had gone down threefold, *i.e.*, to one-third. This, he thought, was a very satisfactory result for six years' work. From the electric lighting stations of this country the output was something enormous—674,000,000 units—and this did not include any of the power stations, such as the big Newcastle Company, and no entirely railway or tramway stations. It meant that these stations alone were using 1½ to 2 million tons of coal per annum on a very moderate assumption. Whilst he admired the authors' Paper and their suggestions, he believed it would be better to simplify all installation work, to reduce the cost of getting into the houses, and simplify the methods of charging as much as possible to a flat rate or two or three flat rates for different conditions. They should not have things that even electrical engineers could not understand. If installation engineers could not understand the maximum-demand system, it meant there was something wrong, for however theoretically perfect it might be, it was obvious that practically it was imperfect.

The President (Col. Crompton), summing up a few of the points raised in the discussion, said it was very interesting to notice how completely each speaker had taken part in the discussion from his own point of view only. Some had to deal with a class of district where the ground was already very completely covered; it was impossible in such a case to believe that if the consumers had to spend a great deal of extra money on the lamps they would not make a saving on the amount they had to pay to the supply company. Others, like Mr. Sparks, had districts which were not at all filled up, and where there were an enormous number of consumers yet to be coupled up. These stations would be affected to the good by the advent of the "wire lamp"—he was indebted to Mr. Mordey for the word. Supply stations had got to a very asymptotic point on their curves as regards cost, and nothing could help very much except greatly increased outputs and better load factors. Those who thought that great efforts had not been made to increase the load factors were entirely wrong. Engineers had been giving the matter much attention during the past few years. Enormous efforts had been made; publicity departments had been organised and had been quietly at work, and he knew that in cases coming within his own knowledge practically everything had been done that was possible to get the lighting load. Everything had been done to supplement this by heating and power loads, and with most disappointing results. The heating came on at the same time as the lighting, and made the load factor worse. The power load also had been very disappointing, *i.e.*, the load factor from power itself had been much less than had been expected. They must not forget the fact that they always had to pay practically 10 per cent. practically throughout England to the local authorities in the form of rates, and this was much more likely to increase than decrease. Again, they knew the cost of fuel was more likely to go up than down, and, generally speaking, these increases were quite likely to counterbalance all that they as engineers could do—the very little that they could do—by improving their machinery and improving their organisations. Therefore, they had really to consider this one great question of the equitable nature of the charge to the consumer, and he thought they were indebted to the authors for having brought the matter before the Institution. The Norwich system was a most important one. It was based upon a system which they had been used to all their lives for their water, and it was practically what they would all have to do eventually for electric light. It might not be at once, or for ten years, but he was convinced that ultimately they would be rated when the great electric supply concerns passed into the hands of the local authorities upon the rateable value of their houses *plus* a small charge for the electricity used. If that was to be so at a later period, why should they not work upon it now? It was an eminently equitable method, for it was quite certain that the causes which led up to this method of charging for water were based on the supposition that it was not right that large premises should skimp their water supply for sanitary and hygienic reasons, and he thought it would not be very far distant when electric supply would be considered of equal importance to water supply; and, that being so, why should not it be run on the same simple basis? Anyone could understand it: 5 per cent., or whatever the amount was, on the rateable value of the premises, and a penny a unit, or whatever the charge might be. This would get over the immense injustice of the huge premises—such as the large Government buildings in Kensington—which electric supply companies had to supply, for the lighting of which during a few hours each year every other small user in the district was practically contributing.

Written contributions to the discussion have been sent in by Mr. J. Horace Bowden, Mr. J. E. Tapper, Mr. C. E. Skelton, and Mr. W. R. Cooper.

Mr. J. Horace Bowden (Borough Electrical Engineer and Manager, Poplar) writes that he is placed in a possibly unique position, having control of an undertaking possessing a power load which preponderates over the lighting load. During the current year he estimates that the maximum demand for power on the Poplar undertaking will be 1,700 kw. and the output 4¼ million units, equal to a load factor of 28·54 per cent.; private lighting 1,000 kw. and the output one million units, equal to a load factor of 11·41 per cent.; and public lighting 200 kw. with an output of ⅔ million units, equal to a load factor of 42·81 per cent.; making a total maximum demand of 2,900 kw.

Digitized by Google



with an output of 6 million units, equal to a net load factor of 23·62 per cent. He anticipates that the average price received will be, approximately :—Power, 1·05d.; private lighting, 5·43d.; and public lighting, 1·5d.; or a net average price of 1·52d. The diversity factor for power upon this estimate is 3·75; for private lighting, 2·5; and for public lighting, nil; or a net diversity factor of 3·06, with a total of 9,075 kw. connected. The standing charge will be, approximately :—Interest and repayments, £15,000; other charges, £7,000; total, £22,000; and he wishes to show a net profit of something in the nature of £4,000, making a total standing charge upon the consumers of, say, £26,000, whilst the running charge will probably be about 0·45d. per unit. According to the principle laid down by the authors, he continues, each consumer should be charged equal to the extent of the maximum demand he may possibly make upon the station, *i.e.*, the capacity of his total connections, although in their examples they do not adhere to that principle. By this system the charge at Poplar should be £2 18s. 6d. per kw. connected, and 0·45d. per unit to produce the same total revenue; and this would reduce private lighting by 1·22d. per unit to 2·21d.; public lighting would be reduced by 0·86d. per unit to 0·64d.; but the price to power consumers would be raised on the average by 0·45d. to 1·5d. In this statement 71 per cent. of the business is for power purposes, upon which the metallic filament lamp has no effect, and Mr. Bowden contends that it is, to say the least, impracticable. As it is impossible to compute the actual value of each individual connection to a system unless the demand is constant throughout the year, he says, it is necessary to resort to classification and allocate to each class its full share of the standing charges as ascertained by the maximum demand upon the station. Public lighting and 100 per cent. load-factor power consumers have no diversity factor, and therefore the standing charge applicable to this class of supply is easily ascertained, a cheap supply being obtained by virtue of the load factor only. Lighting for office, shops, and other business premises of that class should also be governed by load factor and prices fixed according to business hours. The charge to power-users giving an intermittent load must be governed by diversity as well as load factor; the efficacy of this is exemplified in the records of the Poplar undertaking, which has the greatest demand of this class in the Metropolitan area. Mr. Bowden then expresses the opinion that it is the method of charging for domestic purposes to which the most serious consideration must be given, as here is a field capable of enormous development in which cultivation has barely begun. Metallic filament lamps will do much, but cheaper and more perfect cooking and heating appliances will do more; and until we can hope to have the latter, Mr. Bowden thinks that this class of supply must be entirely separated from all others and be charged upon its merits. His opinion is that the time is not far distant when it will be feasible to separate the standing charges in such a manner as to allocate the cost of each individual service and fix an annual service charge to each consumer. The latter would include wiring in some cases, fittings, meter, and connection to mains, to which would be added a charge per kw. for the maximum consumable divided by the diversity factor for the domestic class of load, making in all one fixed annual sum, unless the connections be augmented or reduced. The energy would be charged for as metered at the running cost, which, in a municipal undertaking, would be subject to revision each year similarly to the general rate.

Mr. J. E. Tapper (Resident Engineer, Beckenham Urban District Council Electricity Works) states that in his district one house in six is already supplied, against an average all over the country of only one in ten, and the prospect of picking up a sufficient number of new consumers to cover the immediate loss is very remote. Under-estimating the position, if anything, it is quite possible for the 1,200 consumers at the station referred to to effect a reduction in their total consumption of 25 per cent. To give the same revenue, therefore, as at present, 33⅓ per cent. in consumers must be added to the mains at a capital cost of £3,500 for services only, or an additional annual charge of £200, *plus* extra cost of maintenance of services and collection. During the years occupied in securing the additional consumers it is possible that the undertaking may have to run at a loss unless either meter rents or the prices charged per unit are raised. Mr. Tapper also refers to the power factor of the transformers used for metallic filament lamps, which, apparently, contrary to Mr. Ruthven-Murray, he estimates at 50 per cent. To prevent the carrying capacity of the mains and plant being reduced in this proportion, he advises his consumers to put in transformers which on normal working load are nearly fully loaded.

Mr. C. E. Skelton writes that he does not envy the task of him who seeks to convince the British public that one unit of current is worth more, say, between 5 p.m. and 7 p.m. than at any other hour of the day; he suggests that it would be nearly as wise for a restaurant proprietor to ask for increased prices at the time of his peak of load.

Mr. W. R. Cooper thought there would not be any great falling off in revenue except on alternating-current networks, and this would be more than counterbalanced in many cases after a time by the new fields rendered available by metallic filament lamps. Any restrictions on consumers would be most unwise, and the raising of prices as a solution of the difficulty should be adopted only as a last resource, as it might interfere seriously with the use of electricity for purposes other than lighting. Mr. Cooper advocated modification of our methods of supplying small consumers to imitate those in use on the Continent. There should, he says, be no great difficulty in running a service cheaply along a whole block of buildings, say, under the first floor windows. Such methods, combined with the cheap Continental system of wiring with unprotected wires, would do much to improve the situation. But this would not come about without some combination between contractors and station engineers.

Mr. A. H. Dykes, replying on behalf of both authors, showed the diagram below, which relates to a large alternating-current station. The curve for 1907–8 had started well above the curve of the year before, but in October of last year it had a bad attack of metallic filament lamps, and the curve fell below the curve of the year before. It went on falling, until in January of this year it got below the output of two years before, and it was still going down. This was not a case of the consumers falling off, for the rate of increase in this respect had been well maintained, as shown in the footline to the curve. He knew of single consumers in London who had reduced their bills by as much as £2,000 a year. Mr. Hirst had been a maker of lamps for years; when the conditions altered, he found himself in the possession of a lamp which would give three times the light for the same amount of current. At the same time the station engineer found the conditions changed, and his current was able to give three times the amount of light that it did formerly. Mr. Hirst's advice to the station engineer was to continue to sell current at the same price, and cheerfully to endure the loss for a longer or shorter period, in the hope that eventually he would recoup himself. It was to be expected, therefore, said Mr. Dykes, that Mr. Hirst would sell his new lamps at the same price as the old, and trust to the

Lamps Connected :

1905–6	...	...	... 102,000
1906–7	...	...	... 108,000
1907–8	...	...	... 113,000

increased sales to repay him. Mr. Wright had stated that if the output of the Marylebone station were doubled the cost would immediately come down from 4½d. to 2½d. Then, Mr. Dykes contended, if the criticisms on the Paper were valid, Mr. Wright should have reduced his price from 4½d. to 2½d. a year or two ago, and the increase in new consumers would have more than recouped the loss. Mr. Bowden, in his communicated remarks, had made two mistakes. He had added all his expected profit on to the rental charge, and, secondly, he had charged the consumers on the capacity of plant or lights installed instead of on their contract demand. The effect of this, of course, would be the same as the original Hopkinson method—to reduce the lights installed. Nevertheless, the authors agree that the effect of their system on his figures would be to increase somewhat the charge for power and reduce it for private lighting, and they think that this would be equitable. Meeting the criticism made by some speakers that the system proposed by the authors takes no account of the diversity of the motor demand, they suggest that this is easily met by charging power consumers a lower rental per kw. of contract demand and public lighting a somewhat higher one than lighting consumers, the exact difference depending on the ratio betwen their diversity factors and the proportion which each bears to the total demand on the station. In conclusion, the authors suggest that the Institution should call together a committee of those most interested in the matter of obtaining the consent of the Board of Trade to raising the statutory limit of price chargeable; that this Committee should consider whether joint action is advisable, and, if so, should formulate proposals.

Cambridge University.—The inauguration of the Chancellor-Elect, the Rt. Hon. Lord Rayleigh, F.R.S., will take place to-morrow at 4 Carlton Gardens, Pall Mall, London, at noon.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

We have received a copy of the preliminary programme for the thirteenth Annual Convention of the Incorporated Municipal Electrical Association, which will be held in Nottingham from June 30th to July 3rd.

On the first day, Tuesday, June 30th, the Association will be welcomed by the Mayor of Nottingham, after which the President—Mr. H. Talbot, the City Electrical Engineer—will deliver his address. This will be followed by the reading and discussion of Papers, and subsequently the Chairman and Members of the Electricity Committee will entertain the Association at luncheon. In the afternoon various works will be visited. Wednesday, July 1st, will be devoted to a whole day's excursion to Dovedale. The Annual General Meeting will be held on the morning of July 2nd, and in the afternoon the electricity and other works will be visited. The members' annual dinner will take place in the evening. The Conference will come to a close on Friday, July 3rd, the morning of which will be devoted to reading and discussion of Papers.

The following are some of the subjects which will be discussed during the Conference:—The Experiences of a Convener in Establishing an Electrical Undertaking; the Equipment of a Testing Department; A.C. Accumulator Sub-stations; the Designing of Electrical Generating Stations; Overhead Equipment.

It may be mentioned that this is not the first time that the Association has visited Nottingham, for during the Derby Convention of 1904, under the presidency of Mr. T. P. Wilmshurst, the Borough Electrical Engineer at Derby, a visit was paid to Nottingham, several Papers being read and discussed in the morning and the annual dinner held there in the evening.

POLYPHASE MOTORS FOR INDUSTRIAL PURPOSES

Glasgow Discussion

The Paper on the application of polyphase induction motors for industrial purposes, by Mr. G. Stevenson, an abstract of which was given on page 629 of our last issue, was read and discussed at Glasgow on Tuesday, April 14th. It will be remembered that the author was strongly in favour of squirrel-cage motors used in combination with friction clutches, as opposed to slip-ring motors.

Mr. Campbell McMillan said that the author had taken two classes of motor for the engineer engaged in the application of induction motors to choose from—those with short-circuit or squirrel-cage rotors and those with slip-ring or wound rotors—but he thought he might add a third class—those with internal resistance. They did not require any slip-rings, and in many cases they were very much simpler and were recommended up to a certain size—he thought about 50 horse-power. It was interesting to note that in the comparison of prices they would vary very much according to the copper market, because the chief gain in the squirrel-cage rotor was the relatively small amount of copper in the design. In connection with the very neat method of starting patented by Mr. Meyer, simplicity of operation was obtained at the expense of limiting the freedom of the designer, and anyone who stood up against the possibilities of fitting windings into motors according to desired characteristics would relinquish with the greatest reluctance the freedom to change over from the delta to the star connection as the requirements demanded. At the beginning of the Paper it was stated that, even if starting devices were included, the squirrel-cage motor came out still cheaper in sizes up to and including 50 horse-power, because the starting gear for that type was much simpler and less expensive than that required for the motor with wound rotor. But he thought that the occasions on which the throw-over switch could be adopted were rather limited. In connection with clutches, he remarked that if there was any defect in the machinery, the time required to obtain the full speed might mean a great amount of heat generated in the coil, and provision must be made for the dissipation of that heat. He thought that had been the chief trouble in most clutches—not that they failed to grip, but that they did not dissipate the heat in a proper manner.

Mr. John S. Nicolson (Glasgow University) noted that the author, in speaking of the squirrel-cage machine, said that the absence of moving contacts made it absolutely sparkless, and therefore specially suited for operation in mines or mills where dangers from explosive gases existed, but later said that machines up to 20 horse-power might be used with an air-break switch, and above that size it was good practice to use an oil-break switch. He should imagine that where squirrel-cage machines were being started with an overthrow switch there would be a little sparking. The author's remarks on the probable saving of power from the use of roller bearings, as opposed to the ordinary cylindrical bearings, corroborated one or two experiments which he had made with 10 horse-power induction motor, where he found that the power required for starting when he took out the ordinary bearings and put in roller bearings was diminished fully 10 per cent., so that in ordinary cases with a long line of shafting the saving of power would be a great deal higher than 25 per cent.

Mr. W. B. Hird (Mavor & Coulson) said that the author laid great stress on the superiority of the squirrel-cage motor over the slip-ring motor for most purposes. The advantages of the squirrel-cage motor were very evident from the manufacturer's point of view, as it was a machine that would give less trouble and be a cheaper machine to make, and from the consumer's point of view also, on account of the smaller attention which one would have to give the machine. The greater freedom from breakdowns was also a point in its favour. He had had no experience of friction clutches for high powers, but from what he had heard he thought he was lucky in not having had experience. There was no doubt that friction clutches were looked upon with great disfavour. A few weeks ago (see Electrical Engineering, March 12th, page 407) Mr. Henry A. Mavor had described an induction motor which he had devised and which he had called a spinner motor, in which the member carrying the stator winding was free to move as well as the motor, which was provided with an ordinary squirrel-cage winding. The whole thing was self-contained in the motor itself, and the extra cost was not more than would cover the cost of any friction clutch on the market. If the load was too big, it was merely necessary to allow the stator to be free, and it would accelerate. It was under perfect control during the whole time, and as the stator came to rest the rotor took up the speed.

Mr. W. J. Belsey (British Thomson-Houston Co.) said that he would like to emphasise the importance of judging an induction motor by what the author called the apparent efficiency, and not so much by the power factor or the efficiency separately. In the first place, the power factor was an extremely difficult thing to measure with any degree of accuracy, whereas the apparent efficiency could be determined pretty accurately.

Mr. J. Hally Craig (British Westinghouse Co.) thought that the author had been a little too severe on the slip-ring motor. Undoubtedly the squirrel-cage rotor had many advantages that appealed to the user and to the purchaser or customer speaking from a commercial standpoint, but the slip-ring rotor had also many solid qualities, if properly constructed. The internal resistance method was not much used in this country, but in America it was largely used.

Mr. Walter H. Tittensor (J. H. Holmes & Co.) said that people were beginning to realise that shafting required money to run, but not many mill-owners would believe that they were wasting 50 or 60 per cent. of their power. There were many cases where small manufacturers could not afford to go in for separate motors, so they put in one motor for the shafting, but if they really wanted to get the best results they should go in for separate motors. With regard to clutches, he was glad to say that he had not had much experience of them in a large size, but he knew a number of people who had, and when he had asked them for their experience they had replied that they would rather not give it. The experience of most people was that friction clutches gripped too suddenly.

Mr. Stevenson, in reply, said that he was altogether against the method of inserting resistance permanently in the rotor. In one device mentioned by Mr. Meyer the rotor was wound with two windings, one being with coils of iron wire and the other with copper. That method was tried and practised, but it was proved that the iron wires got rusted up with use in this climate, and the method was abandoned. In reply to Mr. Nicolson, in the case of fiery mines an air-break switch would not be used, but an oil-break would be used. With respect to the special arrangement of Mr. Mavor, Mr. Hird had said that the extra cost of the spinner motor was not greater than a friction clutch would be, but he thought that if they took into consideration the special bearings, he did not think that that would apply. He thanked Mr. Belsey for his remarks as to efficiency, as that was really a very important point, because manufacturers were often asked to guarantee the power factor and efficiency separately.

ELECTRICALLY-DRIVEN WHARF CONVEYORS

An article in the *Electrical World* (New York), describing some of the purposes to which electric power is put in New Orleans, contains details of two different forms of conveyors in use at the docks. One of these is a conveyor installation for handling bananas and similar cargoes at the United Fruit Co.'s Illinois Central Docks. At these docks four Harris-Edel-

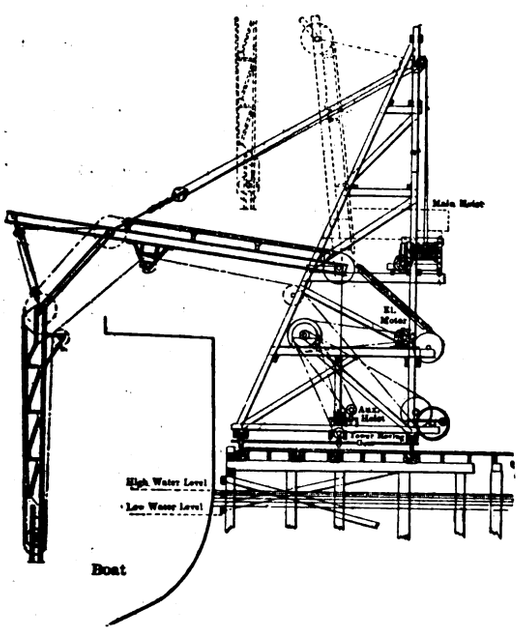

Fig. 1.—Special Electrically-driven Conveyor for Cargoes of Fruit.

ston conveyors have been erected by Messrs. Woodward, Wight & Co. As is shown in Fig. 1, each conveyor consists of an A-frame of steel with derrick and booms, mounted on a movable platform with trucks, in order that the conveyor can be shifted to suit the positions of the hatchways of vessels berthed alongside the wharf. On an endless canvas belt, 5 ft. 4 in. long, are spaced 70 pockets; the spread of the pockets being 36 in. The conveyor belt is lowered into the vessel's hatchway by a marine leg which serves as a frame for the former, the whole leg being attached to the main boom of the hoist by a steel hanger and to an auxiliary boom by a block and fall. The belt is loaded by hand at the different deck levels, and carries its product across the wharf to a platform belt on the shore end of the equipment, delivering the fruit on the platform automatically. Cloth buffers provided at the platform prevent injury to the fruit. From the platform on the docks the fruit is assorted and distributed to the cars of fast fruit trains which are made up on spur tracks terminating near the conveyor.

Each conveyor is operated by a 15 h.p. induction motor, and this motor lifts the main boom, operates the auxiliary hoist, runs the carrier belt, and moves the tower up and down the track, which has a 20-ft. gauge. The tower weighs about 35 tons, but it can be placed in a position and begin unloading the cargo within ten minutes after an open hatchway ship comes alongside the wharf. One man operates each tower, and one tower is used at each hatch. The towers are all adjustable to ships having carrying capacities of 10,000 to 65,000 bunches of bananas, and to a variation in the height of the Mississippi River of 21 ft. 6 in. The main boom consists of a 12-in. I-beam, and the hanger and marine leg frames are of 10-in. channel iron. The conveyor speed is 118 ft. per minute. The different hoists and movements are thrown into service by clutches on the main driving shaft in the tower. The main driving shaft is operated by a 6-in. belt connected with the motor pulley, and the hoist connections are operated through chains and bevel gearing. In actual service each tower is housed to protect its machinery and the fruit handled from the weather. The slack of the conveyor belt is taken up by an idler running in a slot at the lower end of the marine leg.

Each conveyor can handle from 2,500 to 2,800 bunches of bananas per hour, according to the size of the fruit, or about 10,000 bunches per hour from a four-hatch ship. The process of discharging by this means effects a saving of about 50 per cent. in the quantity of labour required, and as the bunches of fruit are handled only twice from the ship's hold to the cars, the saving in damage to the fruit is very great. By the old method of unloading, about 600 men would be required to discharge a large cargo in 24 hours, whereas with the conveyor the same work can now be done in seven or eight hours, and with 300 men. In the old system platforms had to be erected in the holds, on which men stood and passed the fruit from one level to another, sometimes a dozen handlings being required between the ship and the car. This resulted in a loss of 150 bunches through injury by rough handling in a cargo of 30,000 bunches. By the use of the conveyor the damage does not exceed eight to ten bunches, and the saving in time of unloading means about a day's earlier delivery at the interior fruit markets; also, it often means a saving in the value of the ship's charter of from $100 to $200 per diem.

It would be impossible to handle the New Orleans banana traffic without these electrically-operated conveyors. An example of recent rapid unloading is furnished in the case of the steamship *Chirripo*, a four-hatch boat, from which 51,500 bunches were unloaded in 7 hrs. 15 min.; 400 men being employed. Nearly double this force and 24 hours would have been required by hand. The energy cost for operating the four machines two months was only $88, and one and one-quarter

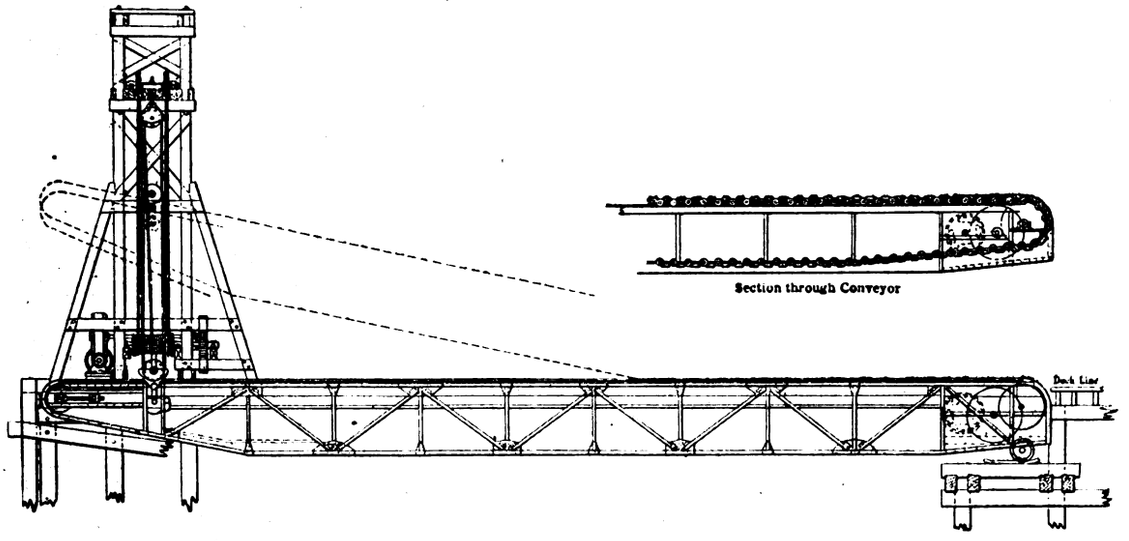

Fig. 2.—Freight Conveyor.

Digitized by Google

million bunches were unloaded. The labourers receive 30 cents per hour. Cargoes of sugar have also been unloaded by the conveyor with a saving of 25 per cent. Inward freight, packages, and barrels not exceeding 450 lb. in weight are also unloaded in this way.

At the Southern Pacific docks in New Orleans some 15 floor conveyors or ramps have been installed to eliminate the hard work of pushing truck loads up inclined planks between the ships and the storehouses. Each conveyor is operated by a 15-h.p. motor. A 10-h.p. 220-volt, direct-current motor is provided to raise and lower the end of the ramp to meet the conditions at the ship. The ramp consists of a travelling platform or escalator about 4 ft. wide and 70 ft. long, which runs about 225 ft. per minute between the edge of the wharf and the central aisle of the distribution shed. Each truck load is pushed by the employee upon the ramp, and the two are carried to the inner part of the wharf, whence distribution is easy. Five of the conveyors were built by the Link Belt Engineering Co., of Philadelphia, and ten by the H. W. Caldwell & Son Co., of Chicago.

The width of the conveyor walk for a single slip is 14 ft. Besides being raised and lowered, the outer end can be maintained by a pin lock in any position. The shore end is supported on rollers. Each side of the walk is provided with a chafing strip of 6-in. by 6-in. yellow pine, each strip being secured 6 in. from the edge of the walk. The conveyors proper consist of double strand chain made of bar steel with 3-in. slats of hard maple fastened to each link and forming a continuous apron; the whole being supported by flanged rollers turning on cold steel shafts. The flanges of the rollers are 5 in. deep. The bed frames or supports for the shore end of the conveyor are constructed on creosoted pine piling. Power is applied by the 15-h.p. motor at the shore end of the conveyor. The motor is of the water-tight type. It is contained in the truss, and is connected by compound gearing with the conveyor shaft. It is started from a controller located adjacent to the conveyor. The outer end of the conveyor is suspended from two two-fold purchases consisting of strong iron blocks and of ¾-in. wire cable wound on a flange drum connected with the 10-h.p. motor. Worm gearing is interposed between the motor and the drum, which sustains the load at any point without brakes or ratchets. Each conveyor is furnished with a safety bar to prevent its dropping in case a cable parts. The ends of the conveyors are fitted with steel aprons.

Heat-Gauges for Hardening Tool Steel.—A description of a magnetic heat-gauge manufactured by Messrs. Taylor, Taylor & Hobson, Ltd., of Leicester, is given in a recent issue of *The Iron and Coal Trades Review*. Every variety of carbon steel (but not high-speed or alloy steel), when heated, becomes non-magnetic precisely at the temperature at which it should be hardened. The gauge, which makes use of this fact, consists of a permanent magnet of horse-shoe shape, with its two poles made of metal, which remains magnetic at temperatures higher than the hardening temperatures of carbon steel. Any small steel object held by these poles and heated by a blow-pipe drops off into the quenching liquid at exactly the right temperature.

The Trollhätten Falls Power Station in Sweden.—This large station, which is now being built, will probably be completed by the end of next year. Both the falls and the station are the property of the State, and a large proportion of the output (about 20,000 h.p.) will be for the State Railways. According to the *Elektrotechnische Zeitschrift*, the station will contain eight three-phase units of 10,000 h.p. each, and three 220-volt exciters of 500-h.p. each. The alternators will generate at 10,000 volt, 25 cycles per second, and will run at a speed of 187 revolutions per minute. An accumulator battery will form a reserve to the exciter sets, and each large unit will also have a direct-coupled exciter. Distribution in the neighbouring district will be effected at the generating pressure of 10,000 volts, but a pressure of 50,000 volts will be used for the long-distance transmission. The 50,000-volt lines will be carried on steel poles spaced 220 yards apart. The most important consumer will be the town of Gothenburg (see also Electrical Engineering, Vol. II., p. 326), which will pay a yearly sum of £2 15s. per kilowatt of maximum demand, and a further sum of 0·066 pence per kilowatt-hour consumed. For every kilowatt over a maximum of 7,000 kw. a yearly sum of £3 2s. 6d. will be paid, up to a maximum of 14,000 kw. The town has guaranteed to take at least 3,000 kw. from the year 1910 onwards. The contract extends over a period of 20 years. Other smaller falls on the same stream (Göta Alf) have been purchased by the State, the total available power amounting to at least 200,000 h.p.

BRITISH WESTINGHOUSE CO.'S REPORT

THE directors' report and balance sheet for the year ended December 31st, 1907, has been issued. There is also submitted a balance sheet as at December 31st, 1906, compiled before giving effect to the capital reduction. In the latter balance sheet are included the transactions of the period from July 31st, 1906 (the end of the previous financial year), to December 31st, 1906. The reasons for altering the date of the termination of the financial year from July 31st to December 31st in each year have been previously explained by the directors. The debit balance on profit and loss account for the period ended December 31st, 1906, was provided for in the reduction of capital, together with other items of loss and depreciation incurred in the past, so far as ascertained up to the time of presenting the petition to the Court.

The results for the twelve months ended December 31st, 1907, showed a marked improvement over previous years. The trading profits amount to £92,383 5s. 5d., from which fall to be deducted:—Interest on 4 per cent. debenture stock, £49,654 2s. 4d.; interest on temporary loans, £14,379 4s.; sundry depreciations (not ascertained at time of reduction of capital), £17,008 14s.; leaving a balance to be carried forward of £11,341 5s. 1d. Having regard to the recent writing down of the various assets, it has not been deemed necessary to make further provision in this year's accounts for depreciation in respect of the works and plant. In their circular of January 4th, 1908, the directors referred to the proposed financial plans. In accordance therewith £250,000 (out of £300,000 authorised) of 6 per cent. prior lien debentures have recently been issued at 98 per cent., and have been fully subscribed. The balance of £50,000 will be held in reserve to be used as and when required for the general purposes of the company. The important arrangement with the American companies has been carried out, whereby indebtedness amounting to £186,374 has been liquidated by the transfer to the American companies of shares in the Traction and Power Securities Company, Ltd., at their par value. Out of the proceeds of the prior lien issue, the loans from bankers will be paid off, and a substantial sum added to the working capital of the company. The institution of economies throughout the administration is continuing to have the careful consideration of the directors. During 1907 there was a substantial increase in the volume of the company's business. At the present moment demand is slack, but the company's improved commercial position, both at home and abroad, will enable it to take advantage of any revival in trade. In accordance with the Articles of Association, the retiring member of the board is Mr. J. Annan Bryce, M.P., who, being eligible, offers himself for re-election. The meeting will be held at Hamilton House, London, E.C., on Monday next.

Swiss Telegraphs and Telephones.—An American Consular report gives some details as to the management of the Swiss Government telephone and telegraph systems. Distances in Switzerland being short, the service prompt, and the rates low, the telegraph and telephones are liberally patronised. Long-distance connections are made with all the local or urban telephone lines, enabling patrons to communicate with all cities and towns in the country. There are also international connections with all the countries bordering on Swiss territory. A feature of the Swiss telephone service is that in addition to owning and operating all the lines, the Government manufactures all the instruments used, and controls the business absolutely. The total length of telephone lines in Switzerland is 10,548 miles. The annual rental charge for offices, business houses, and residences is $12·45 per year. An additional charge of one cent is made for each call in the town. For inter-urban or long-distance calls the rate is 2 to 14 cents for three minutes, according to distance, 14 cents being the maximum rate for any distance in the country. The number of telephone subscribers in 1906 was 53,711. During the year there were 32,071,177 local, 7,251,193 inter-urban, and 299,209 international calls over the Government telephones. The revenue from all classes of calls for 1906 was $829,732; income from rent on 53,711 telephones, $668,702, making a total of $1,498,434. The total length of telegraph lines is 66,683 miles. The total number of telegrams transmitted in 1906 was 4,918,679, of which 2,339,956 were international and 1,698,858 local. The total revenue from telegrams for the year was $1,596,664. There is a Government tax of 30 centimes, equal to a fraction under 6 cents American money, on each telegram sent. In addition to this charge there is a universal rate of one-half cent a word throughout the country, distance not being taken into consideration. A telegram of ten words costs only 11 cents. The international rate is 30 cents per word to New York, 2 cents to France, Germany, Italy, and Austria, 5 cents to Spain, 6 cents to England, and 9 cents to Russia. In addition to the foregoing there is a Government tax of 10 cents on each international telegram or cable. The total income from telephone and telegraph service for 1906 was $3,095,098; expense, $2,231,217; profit to the Government, $863,881.

REPORT OF MARCONI'S WIRELESS TELEGRAPH COMPANY

In submitting their report made up to September 30th, 1907, which will be presented at the annual ordinary meeting to-day, the directors express regret for the delay in its publication. The postponement is stated to have been due, first, to the complex and delicate situation in which the company found itself when His Majesty's Government indicated an intention to ratify the conclusions of the Berlin Conference, and when other governments were considering how far they should go in assenting to the principle of intercommunication. Secondly, the directors felt that they ought, if possible, to come before the shareholders with a definite announcement as to the achievement of the anticipated transatlantic service, the establishment of which had been repeatedly postponed owing largely to the delay in obtaining delivery of the necessary material. The transatlantic service having been established last October, the Board considered it advisable practically to demonstrate its stability and possibilities by testing it in actual operation. The results after six months' continuous working are considered to be satisfactory and encouraging, and are claimed to justify the confidence with which the directors have throughout regarded the feasibility of direct wireless communication with America.

In commenting on the balance sheet, the report points out that these and many other developments have been attained with a capital issue of about 384,190 shares, with the profits which have been allocated to capital account and by financial engagements amounting in all to £94,263 15s. 6d. at September 30th last. Attention is called to the credit side of the balance sheet, on which appear the share interests in the subsidiary enterprises of the nominal value of £2,394,106 10s., which are, together with the patents, set out in the balance sheet at only £242,966 9s. 10d. These holdings represent more than 50 per cent. of the whole issued capital of these companies, and items include practically the whole of the £200,000 share capital of the Marconi International Marine Communication Co., Ltd. By the completion of the arrangements now being made dealing with the transatlantic service, an early accession of income to several of these subsidiary companies is expected.

The report continues:—When the patents were originally acquired in 1897, communications could only be sent a distance of two miles, but as the result of the work on development since that date, communications are now able to be sent 2,500 miles. In all, the company own over 550 patents. The more recent patents cover important improvements relating to new transmitters and receivers which secure increased speed, and improved syntonisation. On the patents are based the licences which are held by His Majesty's Government, Lloyd's, and our associated companies. The British Admiralty are paying £5,000 per annum, for a term of years, for the right of using the Marconi system.

The long distance station at Clifden in Connemara, communicating with the long-distance station at Glace Bay in Nova Scotia, was in October, 1907, so far completed as to admit of its being opened for a limited press service, and in February, 1908, the stations were opened to the public for the transmission of messages between London and Montreal at an inclusive rate of 7½d. per word. A considerable amount of business has already been transacted by means of these stations, and this business is daily increasing. One newspaper in New York stated that it had during five months received despatches, totalling 68,404 words, "promptly and efficiently transmitted by the Marconi system." These stations will be able to cope with a much larger volume of messages when the necessary enlargement and duplication of machinery has been carried out. It is intended to bring up to the same level of efficiency as the Irish-Canadian stations, the two long-distance stations at Poldhu in England and Cape Cod in the United States. The company has an agreement with the British Post Office, whereby the latter engages to grant the same facilities for the collection and delivery of messages by the Marconi transatlantic system as those afforded to the cable companies. A similar agreement has been entered into between the Dominion Government and the Canadian Marconi Company. Up to the present this service has been conducted at speeds varying up to 20 words a minute, but with a comparatively inexpensive modification of certain parts of the existing apparatus, it is expected to attain a speed of 30 words a minute. On the basis of the improved Irish-Canadian service, and of the contemplated English-American service, working the four stations at 12 hours a day at an average net wireless rate of 4d. per word, and at a speed of 20 words a minute, a net revenue (after deducting working expenses) approaching £150,000 per annum is capable of being earned by these four stations. In addition to the total earnings of the long-distance stations at Poldhu and Clifden, the greater proportion of the profits derived from the corresponding stations at Cape Cod and Glace Bay will also pass to this company in the form of dividends, this company holding the majority of the stock in the American and Canadian companies.

The maritime service is progressing most satisfactorily, the North Atlantic being covered by a network of wireless intercommunication. The number of steamers using the Marconi international organisation of ship and shore stations has increased from 80 ships in 1905 to 92 ships in 1906, and 118 ships in 1907 (excluding warships).

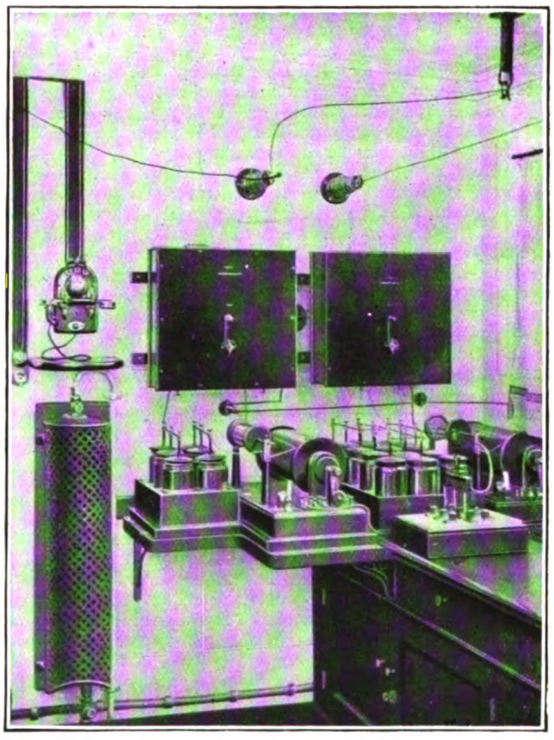
The number of words transmitted and received were 643,534 in 1905, 1,354,549 in 1906, and 1,868,540 in 1907. The net receipts by the Marconi International Marine Communication Co. and its associated companies from this source for the same period were £13,066 in 1905, £27,501 in 1906, and £37,936 in 1907. The Poldhu station has been supplying a daily press service to such of the Atlantic liners as are fitted with the long-distance apparatus. The receipts of the Poldhu station during the last two years amounted to over £9,000.

The report deals with the question of intercommunication as follows:—On the establishment of the above organisation the expenditure was necessarily large, and it has been productive of most promising results, but the very success of our efforts in this direction led to foreign intervention. On the proposal of the German Government, the Powers were convened to two successive conferences, the last and most important of which was held at Berlin in the autumn of 1906, in order to frame an International Convention to regulate the use of wireless communication at sea. The effect of this convention was a proposal made by Germany, and accepted by the majority of the delegates, to make intercommunication between all systems compulsory. Thus the manufacturers of any wireless instrument would be entitled to demand the same access to our wireless exchange as those who used Marconi's system only, even if the said instrument was an infringement of our patents, and this without incurring any of the initial expense we have had to incur in establishing our stations and organising our exchange. A Select Committee of the House of Commons was subsequently appointed to inquire into the matter, and by a majority of one they reported in favour of the ratification of the Convention. In this connection we reproduce the following statement by the Select Committee of the House of Commons that deliberated on this question:—"Whilst the Committee consider that the Marconi Company have exaggerated the case against ratification, under the apprehension that they will suffer commercial injury by the operation of the Convention, the Committee would be very reluctant to make any recommendation which would impede or be injurious to the fair working of their business. They recognise the valuable work which has been done by the Marconi Company as the pioneers of practical wireless telegraphy, and this work is fully appreciated by the nation. From the evidence placed before them, the Committee see no reason to apprehend that the obligations of the Convention, if faithfully carried out by all concerned, will prove injurious to the Marconi Company. If, on the other hand, it is found by practical experience that the Marconi Company are injuriously affected, the Committee recommend that they should be treated with a generous consideration quite irrespective of and without prejudice to their legal position." Under these circumstances the directors have been carefully considering the course the company should now adopt. They remain convinced that the working of wireless telegraphy at sea, that is to say, between moving points, can only be efficient if controlled by one central organisation, and in their opinion the rules adopted by your Company and the commercial organisation which it has established afford the best means for ensuring this efficiency and practicability. But the majority of the Governments do not share this opinion, and this being the case your directors are compelled to take the view that it would be wise for this company's business interests to consider how it may best be found practicable to modify the policy hitherto pursued by the Board, and believe that with mutual goodwill and regard to respective interests, arrangements may be arrived at not only satisfactory to the Governments concerned, but also remunerative to the Marconi Companies, who have invested so large an amount of capital in the establishment of this present wireless organisation.

The company owns a fully-equipped factory adequate to cope with the expanding demand for instruments and installations. Over 500 wireless stations have already been equipped by the company, and the number is constantly being added to. Considerable orders are received each year from the British Admiralty and foreign governments for wireless telegraph apparatus and accessories. The Marconi system is also in use for naval and military purposes in Italy, Russia, Belgium, Chili, Brazil, China, and Siam. The factory is freehold, and is valued as a going concern with its equipment and stock at over £95,000.

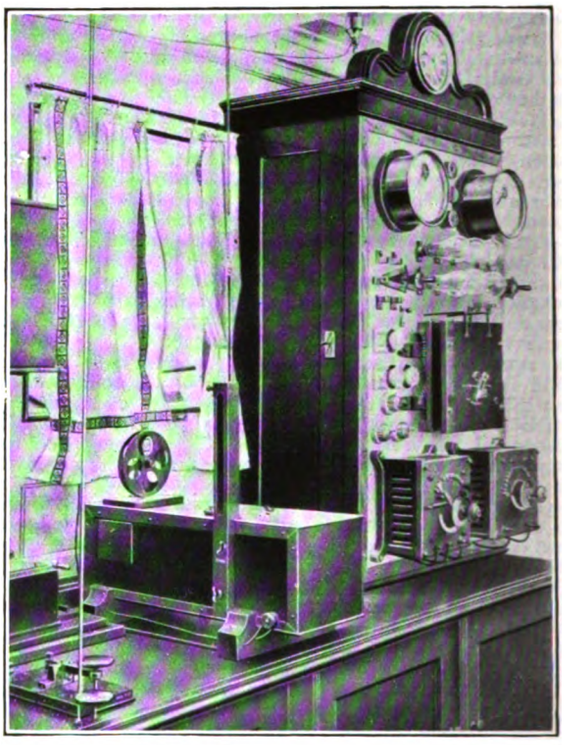
With regard to the Marconi Wireless Telegraph Company of America, the long-distance station at Cape Cod, as is the case at Poldhu, has been supplying a daily news service to ships fitted with long-distance receiving apparatus, and the four shore stations at Seagate, Sagaponack, Siasconsett, and South Wellfleet, on the American seaboard, have contributed their quota to the wireless exchange. The action in respect of Mr. Marconi's

Digitized by Google



magnetic detector patent has been decided in favour of the company. The Marconi Wireless Telegraph Company, Ltd., of Canada, has erected the transatlantic station at Glace Bay, which corresponds with the station at Clifden, and for communication with ships further stations have been completed at Cape Bear, Prince Edward Island, Quebec, Grosse Isle, and North Sydney, and there are now altogether 20 Marconi stations on the Canadian shores and the St. Lawrence River. Contracts have been made with the Government of Newfoundland for wireless stations, and five stations are working on the Labrador Coast. One of these contracts secures to the company exclusive rights for wireless telegraphy in Newfoundland. During the period under review a company has been formed at Buenos Ayres and is now commencing to instal wireless telegraph stations with a view to extending the operations of the wireless exchange to South America. It is the intention of the Argentine Company to erect a long-distance station to communicate with the long-distance station now being erected by the Italian Government, under the supervision of Mr. Marconi, at Coltano, in Italy.

In France the company's interests are represented by the Compagnie Française Maritime et Coloniale de Télégraphie sans Fil, which is earning profits and paying a dividend. In Italy there are 22 Marconi stations which are available for communication with ships fitted with their instruments, and 14 vessels of the Italian Mercantile Marine have already been installed with Marconi instruments.



During the period under review Marconi apparatus has been installed at Lloyd's stations at the Butt of Lewis and the Flannan Islands. The Marconi system of wireless telegraphy is in use throughout the British Navy and at British naval stations in the United Kingdom and abroad. Under the terms of its agreement with the Company, the Admiralty continues to utilise the Company's high-power stations for communication with the ships of the fleet, whether in home waters, in the Atlantic, or in the Mediterranean, within a radius of 2,000 miles. Six of the Trinity House Lightships, viz., the "Sunk," "Gull," "South Goodwin," "Tongue," "Cross Sand," and "East Goodwin," are now fitted with the Marconi apparatus. This business is capable of considerable development.

The directors have been considering for some time past the adjustment of the Company's capital account, and they have decided to ask the shareholders to approve the following resolution to be proposed at an extraordinary general meeting to be held immediately after the annual meeting :—

"That the capital of the Company be increased to £750,000, by the creation of 250,000 preference shares of £1 each, conferring the right to a fixed cumulative preferential dividend (in priority to all other shares) at the rate of 7 per cent. per annum on the capital for the time being paid up on such preference shares, and also, subject to the payment of a non-cumulative dividend of 10 per cent. per annum on the ordinary share capital of the Company for the time being paid up, the right to participate *pari passu* in proportion to the capital paid up with the ordinary shares in any profits not required for the payment of such preferential dividend, and of a non-cumulative dividend of 10 per cent. per annum on the ordinary shares which it shall from time to time be determined to distribute, and the right in a winding up to rank in priority to all other shares for the repayment of capital and *pari passu* with all other shares in any excess after repayment of capital paid up thereon." The proceeds of the new issue will serve to pay off the Company's engagements to bankers and others. There would then remain, in the opinion of the directors, an amount sufficient to carry on and extend the business of the Company, to complete the long-distance stations, to provide these with the necessary land line facilities, and to enable the Company to deal with the orders already received and likely to be obtained. The shareholding of the Company in the subsidiary companies, which should become exceedingly valuable as the long-distance business progresses, should provide further resources for the extension of the Company's business. In March last the directors made an agreement with Mr. H. Cuthbert Hall that he should relinquish the position of managing director and his suggested present and future claims for commission in consideration of a payment in cash and of the allotment to him of 10,000 fully paid-up shares in the Company. Mr. H. Cuthbert Hall has since retired from the board.

Marconi Transmitting Apparatus as Used on Atlantic Liners.

Marconi Receiving Apparatus as Used on Atlantic Liners.

Accompanying the report is the following statement showing the development of the Marconi patents :—Shortly after the incorporation of the Company in 1897, two stations were erected at Alum Bay, Isle of Wight, and at Bournemouth, the distance between these two stations being 14½ miles. About the same time a small steamer was chartered and readable signals on board were obtained up to a distance of 18 miles from the station in the Isle of Wight. In July, 1898, the Kingstown Regatta was reported from the high seas by wireless telegraphy for the *Dublin Daily Express*. In December, 1898, the South Foreland Lighthouse and the East Goodwin Lightship were fitted with the Marconi apparatus for the purpose of demonstrating to Trinity House its value for lighthouse and lightship communication. On March 27th, 1899, France and England were, for the first time, connected by wireless telegraphy by means of installations at the South Foreland Lighthouse, near Dover, and the Chalet d'Artois at Wimereux, near Boulogne, and in September of the same year, during the meetings of the British Association at Dover and of the Association Française pour l'Avancement de Science at Boulogne, communication was maintained by means of Marconi apparatus between the Dover Town Hall and the station at Wimereux. In October of the same year the International Yacht Races between the *Shamrock* and the *Columbia* were reported by wireless telegraphy off Sandy Hook. In November, 1899, a number of Marconi installations were, at the request of the War Office, dispatched to South

Digitized by Google

Africa for use during the Boer War. In March, 1900, the Marconi system was adopted by the Norddeutscher Lloyd Steamship Company, and apparatus was installed on the Imperial Mail Steamer *Kaiser Wilhelm der Grosse*, on the Borkum Riff Lightship, and at the Borkum Lighthouse. The example of the Norddeutscher Lloyd was speedily followed by other shipping companies, among whom were the Belgian Mail Steam Packets, the Beaver and the Cunard lines. In July, 1900, the British Admiralty ordered 32 sets of apparatus, 28 for use on warships and four for Admiralty stations. A further agreement was made with the Admiralty in 1901, and this was again extended in 1903. The Marconi system is at the present time universally used throughout the British fleet and at Admiralty stations at home and abroad. Five stations were erected in the Hawaiian Islands and were opened for public service in 1901, and in the same year the Government of the Congo Free State ordered two stations to be erected, one at Banana in the Congo Free State, and the other at Ambrizette in the Portuguese colony of Angola. On June 1st, 1901, an agreement was made with the *New York Herald* Company for the installation of Marconi apparatus at Siasconsett Lighthouse and on the Nantucket Shoals Lightship, for the interchange of news between ships at sea and the *New York Herald* office. On September 26th, 1901, an important agreement was made with Lloyd's Corporation. The International Yacht Races were again in 1901 reported by the Marconi system.

The construction of the Poldhu high-power station was commenced in October, 1900, and on December 12th, 1901, Mr. Marconi succeeded in receiving at St. John's, Newfoundland, signals from the Poldhu station—distant 2,000 miles over sea. On February 22nd, 1902, Mr. Marconi left Southampton for New York on the s.s. *Philadelphia*, and during the voyage received on the Morse apparatus legible messages at a distance of 1,551½ miles, and distinct signals up to 2,099 miles from the Poldhu station. On March 17th, 1902, Mr. Marconi entered into an agreement with the Government of the Dominion of Canada, providing for the erection and working of wireless telegraph stations in Canada. In April, 1902, the Belgian Government arranged for the installation of Marconi apparatus on all of the Ostend-Dover mail packets, and at one land station. On December 21st, 1902, the first transatlantic messages were dispatched from the Canadian high-power station to Poldhu. In the following month messages were also transmitted to Poldhu from the transatlantic station at Cape Cod, United States of America. Arrangements were made in March, 1903, for the transmission by the Marconi system of American news for the London *Times*, and the first of these messages appeared on the 30th of that month. This service was eventually discontinued owing to the necessity for the provision of more powerful apparatus at the long-distance stations. In February, 1904, Marconi wireless telegraph stations were opened at Broomfield, Chelmsford, and at Amsterdam, for the transmission between the two countries of press messages and Stock Exchange quotations. On May 16th, 1904, an agreement was made with the Sicilian railways for the installation of Marconi apparatus at three of the railway company's stations. On June 4th, 1904, a daily service of wireless news messages all the way across the Atlantic was inaugurated on the Cunard R.M.S. *Campania*, and a daily newspaper is now regularly published on the principal Atlantic liners. On August 3rd, 1904, the wireless telegraph stations at Bari, in Italy, and Antivari, in Montenegro, were opened for public service. In 1905 the Chilian Government requested the Company to carry out a series of demonstrations with a view to the adoption of the Marconi system by the Chilian Navy. These resulted in an order being placed with the Company for a number of installations. On January 4th, 1905, messages for ships at sea were accepted at Post Offices throughout the United Kingdom. On May 30th, 1905, an agreement was made with Trinity House and the Board of Trade relating to the installation and working of Marconi apparatus on lightships and at lighthouses. Six lightships have already been fitted. In October, 1905, the construction of the new transatlantic station at Clifden was commenced. In May, 1906, a contract was made with the Post Office for the supply and erection of two stations in Scotland—at Tobermory and Loch Boisdale. On October 17th, 1907, the Marconi transatlantic system was opened for a limited press service. On February 3rd, 1908, the transatlantic service was opened to the general public for the transmission of messages between London and Montreal.

A list is also given of about 140 ships to which Marconi apparatus has been fitted, and the full text of Mr. G. Marconi's lectures given before the Liverpool Chamber of Commerce on February 24th, and at the Royal Institution on March 13th (see Electrical Engineering, March 19th, p. 430). The accompanying illustrations representing the standard equipment of Atlantic liners are taken from the former of these.

Threatened Telegraph Strike in America.—The *Electrical World* reports that the Commercial Telegraphers' Union intend to order a strike against the Western Union Company unless that company restores wages by June 1st. It is said that the Postal Telegraph Company will not be affected, as it did not pursue the course of the Western Union in reducing wages after the strike of last year.

ELECTRIC LOCOMOTIVES FOR THE DETROIT RIVER TUNNEL

A SHORT description is given in the *Electrical Review* (New York) of one of the six electric locomotives now being built for the Detroit River Tunnel Co. by the General Electric Co., and the American Locomotive Co. These locomotives will be used to haul both passenger and freight trains through the tunnel now being constructed under the Detroit River from Detroit to Windsor, Ontario.

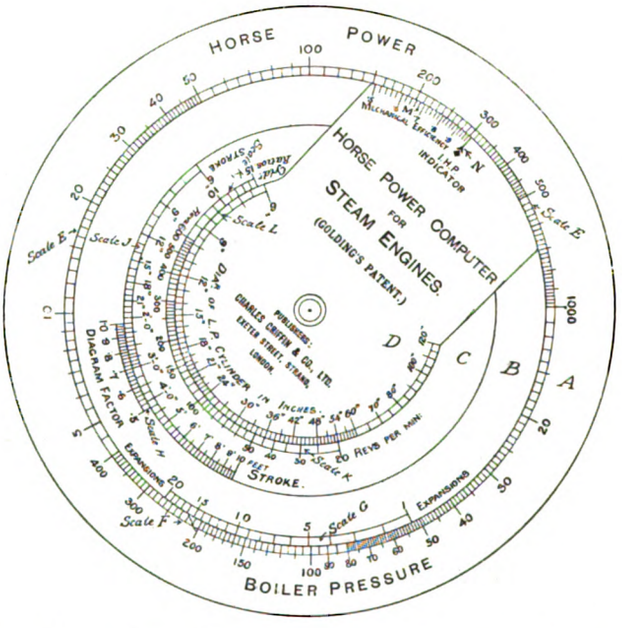
They are moderately slow-speed machines, and weigh 100 tons on the drivers. The frame is of the articulated type, and can best be described as consisting of two four-wheel trucks hinged together. The trucks are of a very solid construction, with cast-steel side frames of truss pattern, carried on semi-elliptical journal-box springs. The diameter of the driving wheels is 48 in. The draw-bars are carried directly on the outer end frames of each truck, the two trucks being hinged together by substantial hinges and pins. By adopting this method of construction the pull of the locomotive is taken directly through the truck frames and the centre pins are relieved of all hauling strains. The superstructure consists of a cab, 15 ft. 6 in. in length, containing the controllers, valves, &c., in the centre of the vehicle, and the usual low sloping ends containing the contactors, rheostats, and air reservoir.

The electrical equipment of each locomotive consists of four GE-209 motors, and the Sprague—General Electric multiple-unit train control. Each motor will develop approximately 300 h.p., and at its hour rating will develop a tractive effort of 9,000 lb., at a speed of 12 miles per hour, while the complete locomotive is capable of hauling a 900-ton train up a 2 per cent. grade at the required schedule speed. The motors are of the commutating-pole type, and are among the largest units of this type yet constructed for railway work. The current will be supplied to the motors from an inverted third rail at a potential of 600 volts. On account of the heavy torque developed, which amounts to 4,050 lb. at a one-foot radius, a pinion is mounted on each end of the motor shaft. The motors will be cooled by forced ventilation, a blower having a capacity of 2,000 cubic feet per minute being installed in the main cab for this purpose. The compressor for the air brakes has a piston displacement of 100 cubic feet per minute.

The P. & O. Batti Wallah's Society.—A local section of this society of past P. & O. electricians has been formed at Birmingham, and a very successful smoking concert was held on Thursday, April 16th, under the chairmanship of Mr. J. P. Kemp. Full particulars as to the local section of the society may be obtained from Mr. G. Sheppard, Local Hon. Sec., 50 Alcerester Road, Moseley, Birmingham.

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the meeting on Thursday:—*Member:* C. D. Burnet. *Associate Members:* F. S. Collings, I. Dalmer, J. H. Fossett, Captain R. C. Hammond, R.E., A. R. Low, L. Oulton, and W. E. Shuttleworth. *Associates:* G. B. Barham, E. T. Larner, and V. I. Stephens. *Students:* A. R. Alderson, C. G. Dickinson, J. H. Eddison, B. F. Hill, R. D. Norman, and J. Stephen.

Birmingham Electrical Division of the Territorial Force.—Negotiations are in progress for the acquisition of a site near the centre of the city for the erection of a permanent drill hall for the use of the three telegraph companies (see Electrical Engineering, April 2nd, page 524). Up to the present, 100 men, out of the total of 498 authorised, have been attested. Each of the eight detachments of the Cable Company will have a wagon and material for laying and working a 10-mile line, and each detachment of the Air-line Company will have material for erecting 10 miles of air-line.



Glasgow Local Section of the Institution of Electrical Engineers.—At the ordinary meeting of the Glasgow Local Section of the Institution of Electrical Engineers held on April 14th, the following nominations for the officers and committee of the section were announced:—*Chairman:* Mr. W. W. Lackie (Chief Electrical Engineer, Glasgow Corporation). *Vice-Chairman:* Mr. S. Mavor (Messrs. Mavor & Coulson). *Chairman of Students' Section:* Dr. Magnus Maclean (Professor of Electrical Engineering, Glasgow and West of Scotland Technical College). *Honorary Local Secretary:* Mr. J. E. Sayers (Messrs. Sayers & Caldwell, consulting engineers). *Members of Committee:* Mr. Charles Day (General Manager, the Mirlees-Watson Co.), Mr. F. Newington (Chief Electrical Engineer, Edinburgh Corporation), Mr. J. K. Stothert (Messrs. Babcock & Wilcox, Ltd.), Mr. W. M'Whirter, Mr. J. S. Nicholson (Lecturer on Engineering Glasgow University), Mr. Joseph Taylor, Mr. Robert Robertson (Messrs. Strain & Robertson, consulting engineers), Mr. E. George Tidd (Messrs. Morris Warden & Co.), and Mr. J. Robertson.

NEW SLIDE RULE FOR STEAM ENGINE CALCULATIONS

THE accompanying illustration represents an ingenious form of circular multiple slide rule for steam-engine calculations, which has been designed and patented by Mr. Henry A. Golding, and which will shortly be put on the market by Messrs. Charles Griffin & Co. The object of the instrument is to perform with rapidity various calculations connected with steam-engines, such as working out the power of an engine of given dimensions, or *vice versa*, to find the size and speed of an engine to develop a given power.

The instrument consists of four concentric discs, suitably engraved, and graduated with logarithmic scales to represent various quantities, such as boiler pressure, speed, size, and power. The outside disc A is provided with two scales E and F, the former representing horse-power and the latter boiler pressure in lbs. per square inch. The second disc B contains two scales G and H. The outer scale G represents the number of expansions employed, and the inner scale H is graduated for various values of the "diagram factor." The graduations of the scale G are proportional to $\frac{1+\log_e r}{r}$ where r represents the ratio of the number of expansions employed. For multicylinder compound engines the number of expansions is, of course, taken

from the cut-off in the high-pressure cylinder to the end of the stroke in the final cylinder. Similarly the value of the diagram factor H, used for compound engines, will be the combined diagram factor of all the cylinders, that is, the ratio of the total mean effective pressures in all the cylinders referred to the low-pressure cylinder, to the theoretical mean effective pressure obtained by expanding steam hyperbolically from the boiler pressure r times. The next disc, C, also contains two scales, J and K, the former of which on the outer edge represents the stroke and the inner scale the speed. This scale, with its extension K, can be also used as a scale of ratio of cylinder areas. The upper disc D also has two scales L and M, the former graduated upon the outer circumference to represent cylinder diameters (for compound engines, the L.P. cylinder), and an extension carrying the scale M to read off the scale E representing mechanical efficiency. Owing to the power of an engine being proportional to the square of the cylinder diameter, the base of the logarithm scale L is double the length of the base of the other scales.

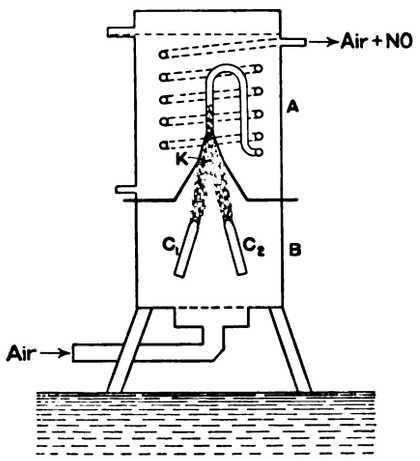
The uses to which the instrument can be put are very numerous, but it is only necessary to consider one case in detail to show the general action. Suppose it is desired to find the I.H.P. of an engine, having given the size, speed, steam pressure, &c. The number of expansions on the scale G is first set against the boiler pressure on the scale F. The theoretical mean effective pressure is then read on the scale F opposite J on scale G. A suitable figure for the back pressure must be subtracted (about 3 lb. for condensing engines and 16 lb. per square inch for non-condensing engines). The given stroke on scale J is then set against a suitable value of the diagram factor, according to the type of engine employed. The diameter of the cylinder (a L.P. cylinder in a compound engine) on scale L is then set against the given speed on scale K, when the pointer N will show the I.H.P. on the scale E. The corresponding B.H.P. can then be seen against the figure for the mechanical efficiency. These operations, with a little practice, can be easily performed in a very small fraction of the time which would be taken for a succession of corresponding operations on an ordinary slide rule. Other operations which can easily be done by varying the order of the operations include finding the theoretical mean effective pressure for a given boiler pressure and number of expansions, finding the actual mean effective pressure for a given value of the diagram factor, finding the boiler pressure required for a given power, size of engine, and speed; given power, pressure, and size of engine, to find the speed required; given power, diameter, speed, and pressure to find stroke required; given power, pressure, stroke, and speed, to find the diameter of L.P. cylinder required.

A number of other minor calculations can also be made, and the apparatus should be of considerable use to engine designers in adjusting the variable quantities to suit given conditions, and an advantage over the ordinary slide rule is found in the fact that there can be no doubt as to the position of the decimal point. The actual value of the ratios of expansion, and also the diagram factor to be taken, vary somewhat with different boiler pressures and types of engines. They will generally be approximately known for the conditions in question, but Mr. Golding has prepared tables of values of these variables for most ordinary cases, which will accompany the instructions sent out with the instrument.

Electrification of German State Railways.—The Prussian State Railway authorities have decided to adopt electric traction on the main lines from Leipzig to Magdeburg and from Leipzig to Halle. The former has a length of 80 miles, the latter a length of 23 miles. The service will consist of short trains at frequent intervals.

Combination of Steel Tube Makers.—It is announced that Scotch steel tube makers have decided to amalgamate and to form themselves into one limited liability company. The leading firms in the combine are Messrs. Stewarts & Lloyds, Ltd., Messrs. David Richmond & Co., Ltd., and Wilson & Union Tube Co., Ltd., but it is expected that practically all the Scotch steel tube makers will join the new undertaking.

Manufacturing Sites.—There has been lately an increasing tendency for the decentralisation of manufacturing industries, and the establishment of works and factories in country rather than urban districts. This movement has been very marked in the districts served by the Great Western Railway, and attention has been called to the facilities that are to be found in the neighbourhood of Reading, Didcot, Banbury, Kidderminster, Oxford, and the South Staffordshire and South Wales districts, and more especially near London between Southall and Slough, where there are already some 40 new factories in full swing. In addition to the concerns which have migrated from towns in England, it is probable that the provisions of the New Patent Act will result in numerous foreign factories being transplanted to this country. In the districts mentioned, the incoming manufacturer not only obtains advantages of cheap land and labour, water, and light, but has also a choice of rail or water transport facilities for the import of raw material, ample railway services for distribution of the manufactured goods at reasonable rates of carriage, proximity to ports, freedom from harassing restrictions respecting buildings and labour, &c., and, what is of great importance, low rates and assessments. The annual saving is in most cases more than sufficient to warrant the capital expenditure in removal, and erection of new buildings.



A Portable Electric Railway Sub-station.—In the course of an article on the system of the United Railways Co., of St. Louis, in the *Electric Railway Review*, a description is given of a portable sub-station used by this company for additional feeding of sections of the line where there is temporary heavy traffic. This sub-station contains one 600-kw., 600-volt, three-phase rotary, three single-phase transformers, together with the necessary auxiliary apparatus. The voltmeters and ammeters are so mounted that they can be easily disconnected and packed in a box of waste, which is kept in the car for this purpose. This was done because it was found that in jolting the car over special work the instruments were very liable to get out of order. This station consists of two cars, the car containing the rotary being equipped with four 50-h.p. motors, and the transformer car being hauled by this motor-car as a trailer. This portable sub-station has been extensively used for special traffic, and was also found of great use on one occasion when a portion of the continuous-current plant in the generating station broke down.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

A MEETING of the Faraday Society was held on Tuesday last week, when three Papers were presented. T. E. Weston and H. R. Ellis read a Paper upon "The Interaction of Aluminium Powder and Carbon." Experiments were carried out in order to ascertain the conditions under which aluminium would unite with powdered wood carbon, sugar carbon, and graphite. It was found that with each form of carbon, when mixed with finely-divided aluminium, reaction could be caused to take place by firing the mixture with a fuse of barium peroxide and magnesium powder. In all cases a mixture of Al_2O_3, AlN, and Al_4C_3 were produced. The carbide had the same formula as that obtained by Moissan in the electric furnace, and upon being decomposed with water yielded methane.

The second Paper was by Professor A. K. Huntington and Dr. C. H. Desch, upon "The Planimetric Analysis of Alloys and the Structure of Phosphor-Copper." In the microscopic examination of metallic alloys, a smooth surface is treated chemically in such a manner as to differentiate between the structural constituents. Either a difference in level is produced, which becomes visible on illumination, or the reagent may form surface films of oxide or sulphide, so that different colours are produced. Copper-aluminium alloys, which were found by analysis to

View of the Gorbov-Mitkievitch Furnace.

contain 9·26, 10·97, and 13·7 per cent. of aluminium respectively, were estimated by the above method to contain respectively 9·4, 10·2, and 13·7 per cent. Such an analysis can be carried out in little more than half an hour.

The third Paper was by Professor N. Piltschikoff upon "Technical Electrochemistry in Russia." There are three works which prepare bleaching powder and caustic soda, viz., Lubunoff, Solvay & Cie., Zabkowickie Electrochemical Cie., and the Russian "Elektron" Company. There are also several copper-refining factories—the Siemens Co. at Kalakaut, which, however, is at present shut down, and a factory at Moscow, which produces annually 500 tons of electrolytic copper, 1 ton of silver, and about 80 lb. of gold. Tin, nickel, and chromium are likewise prepared. In St. Petersburg there is a similar factory, which has been erected to produce copper from its ores. The method of Laschinsky is used. It has been observed that salts of iron, even in small quantity, are oxidised at the anode with formation of ferric sulphate,

$$2FeSO_4 + H_2SO_4 + O = Fe_2(SO_4)_3 + H_2O.$$

This reduces the current efficiency and lowers the quality of the deposit. Therefore, to avoid this oxidation, the plates which form the anode are coated with lead. The oxygen is thus used to form lead peroxide, and the iron is no longer oxidised. The copper is deposited smoothly up to 1·15 grm. per ampere hour. The study of the electrochemical combustion of air by the process of Gorbov and Mitkievitch is about to be carried out upon a technical scale. The furnace shown in the figure consists of a chamber, *B*, the upper part of which is formed by the funnel, *K*, which is connected to a worm, in which the combustion products can be cooled. The arc is struck between carbon or metal electrodes, C_1 and C_2, and fills the whole of the funnel. The arc is driven into the worm by a current of air. The air, therefore, has to pass through this arc before it is able to pass through the worm; here, however, it is immediately cooled, and thus the oxides of nitrogen, after they have been formed, are not again decomposed by the heat of the arc. Either continuous or alternating currents may be used; with three-phase currents three electrodes are required. The terminal voltage employed is from 1,000 to 3,000 volts, and across the arc it is from 600-1,500 volts. Professor Klobonkoff has perfected a method for tanning hides by the electric current, which prevents fermentation of the bath taking place. In St. Petersburg plant has been erected for the purification of water by means of ozone.

In the *Centralblatt für Accumulatoren und Galvanotechnik* of April 20th, the *English Patent* 8,284 of M. C. Thiellet and M. J. Denard for improving accumulator plates is described. It consists of mixing the lead oxide paste with a gelatinous mixture of silicic acid and then adding potassium chromate to it. When this is exposed to bright light, an insoluble compound of the bichromate and the gelatine is formed. The method of preparing it is to make a pulp of asbestos with sulphuric acid of 1·10 sq. gr. This pulp is then added to stronger acid and water glass (sodium silicate) added. The gelatine solution is then mixed, and finally the bichromate . This solution is then mixed with the active material, dried for an hour in the dark, when it forms a stiff paste, and then exposed to the sun. After exposure to the sun it is insoluble in water and in acids, but, being porous, is well suited for holding the lead peroxide.

In the *Zeitschrift für Elektrochemie* of April 10th, G. Baboroysky and B. Kuzma describe the preparation of silver peroxide. They find that the peroxide is not easily obtained if an anode of silver is employed in a solution of silver nitrate, but that it can be obtained with comparative ease by employing a platinum anode and carefully regulating the current density, so that it represents 0·07 ampere per square centimetre. They consider that silver pernitrate, $AgNO_4$, is first produced by the anodic oxidation of the NO_3 ions. This pernitrate then decomposes, two molecules of it yielding $2NO_3$ and silver peroxide thus :—

$$2AgNO_4 = Ag_2O_2 + 2NO_3.$$

ELECTRICAL SCIENCE

British and American

Properties of Selenium.—It is well known that a selenium "cell" varies in its electrical resistance when exposed to temperature change, to pressure change, to radium rays, to hydrogen peroxide, and to other influences, as well as when exposed to ordinary light. The question arises whether these resistance changes are due to the same ultimate property of selenium. In the *Physical Review* for April, this point is discussed by F. C. Brown and J. Stebbins. They have made an extensive series of new experiments on these phenomena, and some of their results and conclusions are of interest. Their experiments on the change of resistance produced by liquid pressure show that the change is about 0·05 per cent. per atmosphere, and that this value is a function of the E.M.F. used in measuring the resistance. Increase of pressure has a harmful effect on the sensitiveness of any selenium cell to light, at every pressure between one atmosphere and one hundred and sixty atmospheres. Temperature rises were found to have a similar effect on the light-sensitiveness. In either case the light-sensitiveness was a function of the initial resistance of the selenium cell. Within the limits of error of the experiments the rate of change of sensitiveness with resistance, whether the resistance changes through pressure or through temperature alterations, was the same for all the experimental curves obtained. Finally, the effect of radium and of hydrogen peroxide in decreasing the resistance of selenium was as much as 35 and 99 per cent. respectively, and the light-sensitiveness followed rules very similar to those mentioned above for the effects of pressure and temperature. The selenium cells used in the experiments were of three kinds, namely, those made by Ruhmer, by Giltay, and by the authors themselves, following Bidwell's directions. When exposed to light the conductivity of the first increased twenty times, of the second, seventy times, and of the third about nine times.

Continental

An Electric Hygroscope.—A distinctly novel device for the detection of minute traces of moisture is described by J. Pionchon, in the *Comptes Rendus* for April 13th. It is based upon the well-known property of a clean glass surface of attracting moisture in proportion to the moisture of the atmosphere in contact with it. A glass tube 10 cm. long, closed at one end, is silvered inside and out to within 1 cm. of the open end. The bottom is then cut off, leaving a fresh cut which separates the two silvered surfaces. This cut is the sensitive portion of the instrument. The cut is, however, not left in the rough state, nor fused, but is polished with fine emery. Wires are connected with the inner and outer coatings, and are inserted in a circuit containing a galvanometer and a battery of 100 volts.

Digitized by Google

The deflection of the galvanometer is then found to vary greatly with the moisture of the atmosphere. The mere approach of a moist body affects it. The hand held at a distance of 1 cm. produces various effects in accordance with the part which happens to be near the sensitive surface. The back of the hand produces a deflection of, say, 3 or 4 cm. The point of a finger throws the spot right off the scale. The amount of moisture liberated by the heat of the hand from a paper tube is easily detected. A valuable property of the new hygroscope is the constancy of the zero, which is rapidly recovered.

Ionisation of Colloids.—Some light on the puzzling phenomena of the electric transportation of colloids is shed by the researches of A. Mayer and E. Salles, described in the *Comptes Rendus* for April 13th. As a typical colloid they used the trisulphide of arsenic, As_2S_3. It is usually supposed that the particles of the colloid solution are uniform in size, and have all the same electrical charge, if any. This would imply a uniform rate of transportation. Such a uniform rate is, however, not observed. In fact, the repulsion of one electrode is greater than the attraction of the other, so that if a small column of the colloid solution is enclosed in a long column of liquid, the front end of the repelled column advances less rapidly than the rear portion. The authors make it very probable that the whole motion is not due to any charge of the colloid particles themselves, but that these are dragged along by the motion of ordinary electrolytic ions evolved from them. There is no motion at all unless the E.M.F. suffices to produce traces of electrolysis. The speed grows more rapidly than the E.M.F. The addition of an electrolyte like KCl increases all the speeds. Besides, the preceding colloid may be observed to thicken, while the following colloid thins out. The electrolytic view is corroborated by observations with the ultramicroscope.

Longitude by Wireless.—In connection with the proposals recently brought before the French Academy by Bouquet de la Grye, E. Guyon quotes, in the *Comptes Rendus* for April 13th, a resolution adopted by the Bureau des Longitudes on January 22nd. The resolution, after referring to the gratifying success of the Morocco naval service and the hour signals from Camperdown (Halifax), draws special attention to the usefulness of the Paris-Brest hour service inaugurated by C. Tissot with the aid of the Eiffel Tower installation. The resolution further details the steps which would be necessary for the establishment of an international service for the determination of longitude at sea. A determination of longitude requires an observation of an astronomical phenomenon involving right ascension, such as the southing of the sun or a star, and a simultaneous reading of time. The difference in time between the chronometer reading and the time at which the same astronomical event takes place under the standard meridian is the longitude expressed in time. A wireless service of time would eliminate all errors involved in the rating of chronometers. Such a service can only be efficiently organised by an international committee of electricians and seamen. M. Guyon has been instructed by the Bureau des Longitudes to take the first steps towards the organisation of such a committee.

THE DEVELOPMENT OF THE TURBO-GENERATOR

Mr. G. G. Stoney devoted the first of his afternoon lectures on the development of the modern steam turbine and its application, at the Royal Institution on Tuesday, to the history and present state of the design of steam turbine-driven electrical generating sets, as manufactured by Messrs. C. A. Parsons & Co. At the outset he explained how the advantages of turbine plant over reciprocation engines are more particularly shown in the large sizes, and then proceeded to deal with the development of the steam portion of the set. He described the first Parsons turbine of 10 h.p., running at 18,000 r.p.m., made in 1884, and now in South Kensington Museum, and showed another set of the same design, the fifth to be constructed, which had been in regular service from 1885 to 1896. These machines were of the double parallel flow type. In connection with these very high-speed machines, the use of the Parsons flexible bearing with several loose concentric sleeves separated by films of oil for damping out vibrations was mentioned. Continuing the history, it was shown how the sizes of the machines increased and the speeds became less. The turbines were first run condensing in 1892, and soon afterwards sets were installed in several generating stations, including the Newcastle & District Co., Scarborough, and Cambridge. These machines were of a radial flow design, which was adopted owing to the temporary loss of certain patents, but on the recovery of these patents in 1894 the parallel flow type was reverted to. Several modifications were, however, made on the original designs; the principle of double flow was abandoned, and the balancing pistons introduced. Finer clearances and longer blades were able to be adopted, and a more compact machine with much improved efficiency resulted. A point which was specially mentioned was the advantage of parts where the clearance was small being as thin as possible, as the heat produced by any accidental touching was then a minimum, and serious trouble was avoided. The famous 350-kw. machines which solved the vibration troubles of the Metropolitan Electric Supply Co. at Manchester-square, were spoken of, and also the 2,000-kw. turbo-alternator erected at Elberfeld in 1900. With this progress the steam consumptions were greatly reduced, and with the 3,500-kw. sets at Carville a figure as low as 13·2 lb. per kw. hour had been recorded. A drawing of one of the 6,000-kw. turbo-alternators now under construction for Sydney was shown. Attention was particularly drawn to the effect or economy of a high vacuum in the condenser, and the Parsons vacuum augmenter was described.

After showing a collection of lantern slides of typical turbines, Mr. Stoney passed on to the consideration of the development of the electrical portion of the high-speed generating set, and commencing also with 7½-kw. machines of 1884, running at 18,000, he followed out the stages of development of the Parsons designs which we have already dealt with more fully in Electrical Engineering, April 9th, page 543, in connection with Mr. Stoney's recent Paper before the Institution of Electrical Engineers. The early experiments with compensating windings were spoken of, and the Gramme ring design used for a short time on account of patent troubles. It was in 1903 that the present form of compensating winding was used. A number of slides illustrating the various stages of the designs was shown, and, in conclusion, it was stated that steam turbo-alternators of 20,000-kw. capacity had already been designed in connection with the schemes for the power supply of London.

THE STRANG PETROL-ELECTRIC RAILWAY CAR

A good deal of attention is being paid in America to the development of petrol-electric cars for use on railway branches where the traffic is not sufficiently dense to warrant the use of steam trains or electric cars on short headway. One of the latest designs of car of this nature, which differs considerably from some other cars in use (see Electrical Engineering), is described in the *Electric Railway Review* (Chicago). The main feature of the "Strang" system is the employment of a battery somewhat after the manner of the "auto-mixte" system to assist the generator at times of heavy load. The generator and engine have a capacity sufficient for normal requirements, but when starting or when ascending a grade the storage battery takes care of the "peak" of the load. The storage battery is charged while the car is coasting down grades, coming to a stop or standing still; the gasoline engine running until it is automatically throttled as the batteries attain the full capacity.

The car measures 66 ft. over all, is 9 ft. 6 in. wide, and 14 ft. high. The interior of the body is divided into an engine-room, 13 ft. long, and two compartments, smoking and non-smoking. An observation platform is provided at the rear, which will seat five passengers. The total seating capacity is 75. The weight complete is 114,000 lb. The engine is of the vertical four-cycle type, having six cylinders, 10½ by 9 in., with a continuous rating of 150 h.p. at 425 revolutions per minute. The generator is of 85-kw. capacity at 250 volts. It is a direct-connected shunt-wound interpole machine. There are two interpole motors of 100 h.p. each, series-wound for 250 volts. The battery comprises 112 Planté type cells, having a capacity of 300 ampere-hours; General Electric type M control is fitted with connections for supplying current to a second car, and Westinghouse automatic air brakes. The cooling and heating system consists of an electricaally-driven centrifugal pump, which circulates the jacket cooling water through either the radiators on the roof or through the heating pipes in the passenger compartment.

In starting the engine power is fed from the storage battery to the generator, which, acting as a motor, drives the engine up to speed. The car carries sufficient petrol to run it 200 miles, and consumes about six-tenths of a gallon per mile.

The passenger compartments are heated by pipes connected with the water system. This car will maintain a speed of 55 miles an hour. It can be made the motor-car of a train, being capable of hauling three trailers carrying 75 passengers each. In the event of mishap the double system of power allows its batteries to carry it, for 15 miles if necessary, to a station. The car was built by the J. G. Brill Co. for the Strang Gas-Electric Car Co. of New York.

Accident on Barmen-Elberfeld Suspended Railway.—An accident in which five persons were slightly injured occurred on April 11th. An empty train ran into another train standing in a station, and damaged the cars considerably, but both trains remained hanging safely on the rail, although according to the *Elektrotechnische Zeitschrift* the stationary car was lifted and derailed. That the cars would fall in the event of a collision has been one of the objections to the introduction of such a mono-railway in Berlin (see Electrical Engineering, March 12th, page 405).

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published April 16th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.
Names in brackets indicate communicators of inventions from abroad.

1907 Patents

7,642. H. H. LAKE (*Parker Clark Electric Co.*). Carbon filaments and others having a negative temperature-coefficient tend to carry the greater proportion of the current through the central portion of the conductor, as the surface is more rapidly cooled and is consequently of a higher resistance. In order to work the surface of the filament at a high temperature, the filament may be constructed with a core of high resistance carbon, covered with a layer of combined non-crystalline silicon and carbon, and a final coating of dense, pure silicon. A plain cellulose or a graphitised filament is heated in the presence of a volatile silicon chloride, and a suitable gas for taking up the hydrochloric acid produced. To obtain the final pure surface deposit of silicon, a little CO_2 is introduced. A high operating temperature with a high efficiency is obtained with such a filament. Four claims, no figures.

8,153. BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). In order to drive a load at speeds varying over wide ranges, two motors are sometimes employed, one connected to the load through low speed gearing and the other connected to drive the load at high speed. To vary the speed of the motors, they are supplied from a motor-generator driven from the supply mains, and the generator voltage is varied. When changing from the low-speed to the high-speed motor, the voltage of the generator must be lowered from its maximum to its minimum value. This cannot be done quick enough, and according to the present invention, after the low-speed motor has reached its maximum speed, the generator (which is generating its maximum voltage) is connected in series with the high-speed motor to the supply mains. Current flows in opposition to the generator voltage, and drives the high-speed motor. The generator voltage is then gradually reduced, thus increasing the voltage and speed of the motor. By providing the generator with a series winding, which will oppose the main field when the generator and motor are in series, the voltage of the motor will be automatically increased with increasing load. By adding the generator voltage to the supply mains the speed of the motor may be further increased. Four claims, one figure

10,071. BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). A method of supporting the filaments of incandescent lamps, and especially suitable for tungsten filaments. The filaments are attached in the usual way to radial arms at the foot of the lamp, and the ends of the loops are supported by hooks at the ends of radial arms of copper or tantalum, the other ends of which are attached by means of glass beads to steel spiral springs, which in turn are supported in a vertical position on a glass pedestal rising from the foot of the lamp. Neither copper nor tantalum tends to combine with the tungsten filament, but if copper is chosen a relatively large diameter wire must be used, as otherwise the copper would melt at the point of contact. The flexibility of the support permits progressive contraction of the filaments, but maintains the proper tension on the filament. The filaments are also protected from jars during transportation. Three claims, one figure.

17,781. A. D. JONES. The enclosed flame arc-lamp, which was described in ELECTRICAL ENGINEERING, February 27th, 1908, page 299. Particulars of the composition in the grooves of the positive carbon were given in this Patent Record for March 5th, 1908, page 365. This specification further states that if a sodium steadying salt is added, an improvement is effected by the addition of a little potassium silicate; if a potassium steadying salt is used, sodium silicate may be added. One of these silicates diluted with water may be used as the binding material to hold the chemicals in the grooves of the positive carbon. The arc with a current of 5 amperes at 70 volts is about one inch long and quite thin. Five claims, three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.
Summaries of the more important of these patents will appear in our next issue.

1906 Patent

26,560A. BURNS. Electrically-operated locks.

1907 Patents

539. RUHMER. Production of high-frequency arcs.
3,215. RUHMER. Apparatus for Hertzian telephony.
5,194. POSTANS. Electrical ignition apparatus.
7,687. WEBB. Radio-telegraphy and radio-telephony.
7,941. BEVIS & ANGOLD. Electric arc lamps.
7,941A. BEVIS & ANGOLD. Electric arc lamps.
7,959. HOWSON. Electric automatic fire alarms.
8,183. MERSHON. Alternating-current machines.
8,364. GES. FÜR DRAHTLOSE TELEGRAPHIE. Receivers for wireless telegraphy.
8,563. DEUTSCHE GASGLÜHLICHT AKT.-GES. (AUER GES.). Manufacture of metallic filaments for incandescence lamps.
8,641. BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Joints between lamp filaments and leading-in wires.
8,903. DAVIS. Electric lamp-holder.
9,868. ELECTRIC & ORDNANCE ACCESSORIES CO. & HALL. Circuit breakers.
11,381. SIEMENS BROS. & CO. & GRIMSTON. Electrical messenger call installations.
11,850. BOTTING & BOTTING. Electric sign switches.
12,402. GRIFFIN. Mechanism for magneto machines.
12,420. LANCASHIRE DYNAMO & MOTOR CO. & STANSFIELD. Dynamo-electric machinery.
12,907. NEWITT. Electrical counting gear.
12,960. MARCONI'S WIRELESS TELEGRAPH CO. & FRANKLIN. Receiving apparatus.
14,150. MOORE & POWLES. Electrical signalling.
14,287. BRITISH THOMSON-HOUSTON CO. & HOPPS. Self-propelled vehicles.
16,364. MAYO & HOULEHAN. Multiple fuse blocks.
16,385. APPLEYARD & QUIGGIN. Electric light fittings.
16,489. SIEMENS & HALSKE, AKT.-GES. Manufacture of a plastic mass from tungsten compounds.
16,513. WISE (*Mailloux*). Apparatus for cooling electric machinery.
17,655. HEYS (*Scott Electrical Co.*). Arc lamps.
17,686. STONE. Space telegraphy.
18,045. FELTEN & GUILLEAUME-LAHMEYERWERKE AKT.-GES. Inverted repulsion motors.
21,087. COOMBS. Diaphragms for telephonic apparatus.
21,408. THOMPSON (*Ges. fur Drahtlose Telegraphie*). Detector for wireless telegraphy.
22,259. ETCHELLS. Controlling locks for electric lifts.
22,349. ETCHELLS. Electric switches.
23,709. UNDERWOOD & SMITH. Dynamo-electric machines.
23,756. DIEHL & BECKER. Electric fans.
24,212. JOHNSON (*Felten & Guilleaume-Lahmeyerwerke Akt.-Ges.*). Electrical targets.
24,702. RENNERT. Electrical fire-alarm systems.
25,187. BRAUN. Bathing tubs for electrical treatment.
26,530. GES. FÜR DRAHTLOSE TELEGRAPHIE. System of radio-telephony.

1908 Patents

559. DRÄGER & DRAGER. Lamps for miners' helmets.
879. HUBBELL. Holders for electric lamps.
2,676. LOEBL & BRITISH EVER READY ELECTRICAL CO. Holders for electric lamps.
7,041. RUHMER. Production of electric impulses of high frequency.

Complete Specifications open to Public Inspection before Acceptance.

1907 Patents

19,477. GAIFFE. Rotary mercury interrupters.
28,649. METALLURGISKA PATENTAKTIEBOLAGET. Magnetic separation of ore.

1908 Patents

7,289. SIEMENS-SCHUCKERTWERKE GES. Regulation of alternating-current commutator machines
7,480. SIEMENS & HALSKE AKT.-GES. Method of testing electrolytic valve cells.
7,493. FESSENDEN. Telephonic transmitters or relays.
7,494. FESSENDEN. Wireless telegraphy.
7,507. OERTLY & DUDLEY. Electrically-heated tools.
7,621. ATELIERS THOMSON-HOUSTON. Alternating-current repulsion motors.

Expiring Patent

The following patent expires during the current week, after a life of fourteen years:—

8,607, of May 1st, 1894. (Amended 1899.) W. P. THOMPSON (*A. E. Keith*). A mechanism for use in automatic telephone exchanges, and consisting of a series of wires for electrically interconnecting the several exchanges. A shaft, on which is carried a series of switch arms disposed radially at different angles, and which is capable of rotation and longitudinal movement, is actuated by suitable mechanism to bring the switch arms in contact with any one of the series of wires. Five claims, three figures.

LOCAL NOTES

ABERDARE: *Electric Lighting.*—The Town Clerk has been instructed to engage a consulting engineeer to report to the Council upon an electric lighting scheme.

ARGENTINE: *Electric Supply.*—The *Review of the River Plate* states that the electric light station in Necochea was inaugurated on the 8th inst. A local company is being formed in Daireaux, Province of Buenos Aires, for the electric lighting of that town.

AUSTRALIA: *Sydney Power-house Management.*—The second report of Mr. G. A. Julius, the expert chosen to inquire into certain matters in connection with the operation of the Sydney City Council's electric lighting scheme, has been made public. This report, says the *Australian Mining Standard*, deals with the question of aldermanic influence; and the conclusions arrived at are summarised as follows:—That the plant in the power-house in August, 1906, was in a moderately good condition, but in view of the rapidly increasing output the city electrical engineer was entirely justified in recommending the appointment of a power-house superintendent to direct and supervise the maintenance and running of the plant; and that during the latter part of 1907 the plant was allowed to fall into very bad condition. The report absolves the Council from blame for interference, and refers to laxity of experience and administration on the part of certain officers. Following on the discussion of the report by the City Council, the Lord Mayor presented a minute recommending that the services of the power-house superintendent be dispensed with, and that Mr. Woof, now in charge of the overhaul of the plant for Messrs. Dick, Kerr & Co., be appointed at a salary of £400 per annum, to be increased on a sliding scale to £500. The minute was adopted.

BARKING: *The Tramway Losses.*—At the last meeting of the Council, the chairman of the Tramways Committee was asked what measures he contemplated to do away with the enormous losses on the running of the trams. The chairman said there was to be a meeting to go into the whole question.

BEDFORD: *Incorporated Municipal Electrical Association.*—The Corporation has delegated the Chairman of the Electricity Committee and the Borough Electrical Engineer to attend the annual conference of the Incorporated Municipal Electrical Association at Nottingham from June 30th to July 3rd.

BELFAST: *Third Party Insurance.*—The Corporation has refused to join a conference proposed by the Halifax Corporation on the question of a mutual insurance scheme against third party tramway risks, for the reason that up to the present the Belfast Tramways Committee has not insured against these risks.

BEXLEY: *Electric Supply Tariff.*—At the last meeting of the Urban District Council the Electric Lighting and Traction Committee reported that they had had under consideration the desirability of instituting an alternative daylight tariff for supply to motors, and they recommended the following tariff:—Up to 2,000 units, per annum, 3d. per unit; from 2,000 to 2,500, 2¾d. per unit; from 2,500 to 3,000, 2½d. per unit; from 3,000 to 5,500, 2¼d. per unit; above 3,500, 2d. per unit. Minimum charge to be £2 13s. 4d. per annum, and charges to be net. Meter rents to be charged in addition, at the same rates as on the existing daylight tariff, and the new tariff to be governed in all other respects by the regulations applying to the former. The report and recommendation were adopted.

BLACKBURN: *Blackburn, Padiham & Whalley Light Railways.*—It is proposed by the Light Railways Commissioners to hold a public inquiry at the Blackburn Town Hall on Friday, May 8th, into the application of the Blackburn, Padiham, & Whalley Light Railways Co. for an order for revival and extension of time.

BLACKPOOL: *Electricity Profits.*—The profit upon the municipal electricity undertaking for the year ended March 31st amounts to £8,476. The output was 3,404,511 units, an increase of 300,000 over the number for the previous year, and it is to be noted that the largest increase in the consumption was for the private lighting. In spite of the largely increased output, the coal consumption was only 153 tons more than in the previous year. The total income was £36,585, generation and distribution charges amounting to £16,140, and interest and sinking fund to £11,969. The capital expenditure to date amounts to £199,052; reserve fund now amounts to £13,151.

BURY: *Tramway Committee's Chairman.*—Col. Hall, the Chairman of the Tramways Committee, has resigned, partly on account of ill-health and partly owing to calls upon his time in other directions.

The net profits of the Bury tramway system for the year ended March 31st were £4,606 as against £5,225 for the previous year. The Tramway Manager points out that the difference is more than accounted for by the fact that the Easter holiday traffic is not included in the accounts for 1907-8. As the agreement with the Heywood Council with regard to the tramways will shortly expire, the Outside Authorities Sub-Committee have been instructed to meet the Heywood representatives with a view to its renewal.

Electricity Accounts.—The net profit for the year ended March 31st, 1908, are estimated at £3,950 against £2,947 for the previous year.

Incorporated Municipal Electrical Association.—The Chairman of the Electricity Committee and the Electrical Engineer have been requested to attend the annual conference of the Incorporated Municipal Electrical Association at Nottingham from June 30th to July 3rd next.

CARDIFF: *Tramway Employees.*—The local branch of the Amalgamated Association of Tramway and Vehicle Workers has asked the Tramways Committee to agree to the formation of a Conciliation Board to deal with all matters relating to the tramway employees which cannot be amicably settled by the tramway manager. Mr. Arthur Ellis, the tramway manager, stated at the meeting of the Tramways Committee last week that hitherto there had been no trouble or misunderstanding with representatives of the tramway men's Union, who now discussed all matters with him. If the suggestion of a Conciliation Board were adopted, he foresaw that the men's Union might not acknowledge his authority if he, for instance, dismissed a man for neglect or misconduct, and they would be constantly appealing to the Board. After a little discussion it was decided to ask the Association to explain more fully what their request was.

COWDENBEATH: *Public Lighting.*—The Fife Electric Power Co. has made two offers in connection with the public lighting in this district. In the first, the company offer to erect 20 1,500 c.p. arc lamps, to supply the necessary cables and connections, and to maintain them, for an inclusive sum of £12 per lamp per annum. For incandescent lighting they propose to supply the lamps and pillars, and maintain them for the sum of 38s 9d. per lamp per annum on a 10 years' contract. These offers have been submitted to a committee for consideration.

CROMER: *Electric Lighting Committee.*—An Electric Lighting Committee has been appointed to take charge of the department. Hitherto this work has been carried out by the Highways Committee.

DARWEN: *Tramways and Electricity Profits.*—There has been a profit on the Darwen electricity and tramway undertakings for the year ended March 31st of only £600, alleged to be due to the rise in the price of coal, and other circumstances. The profit of the Electricity Works alone amounted to £100.

DUBLIN: *International Exhibition.*—In Dublin last week a sale was held of the electrical plant and fittings which were used at the recent international exhibition. The plant included switchboard and instruments, rubber-covered and lead-covered cables, electroliers, brackets, and fittings.

EDINBURGH: *Incorporated Municipal Electrical Association.*—The Electric Lighting Committee recommend the appointment of the Convener, Mr. A. Murray, and Bailies Stevenson and Neill, together with the Electrical Engineer, to attend the annual Conference of the Incorporated Municipal Electrical Association at Nottingham from June 30th to July 3rd.

Electric Lighting Estimates.—The estimated expenditure upon the electricity undertaking for the year ending May 15th, 1909, is £70,230, compared with £65,040, the amount of the expenditure during the current year. Interest and sinking fund are estimated to require £56,070 against £50,065, giving a total estimated expenditure of £126,300, compared with £121,105. The estimated revenue is £136,200 against £132,585, leaving a surplus of £9,900, compared with the estimated surplus of £11,408 at the end of May 15th next. The capital expenditure is put at £33,090, mainly in regard to alterations and additions at the Macdonald Road station.

International Exhibition.—The National Telephone Co. has provided a 50-line switchboard in connection with the International Exhibition. A number of call offices have been erected in the grounds, in addition to two in the Industrial Hall and one in the Machinery Hall. Arrangements have been made for users to be able to communicate with each other in the exhibition or with any part of the city, and trunk connections can be had through the main exchange in Edinburgh.

Underground Telegraphs.—The Postmaster-General has intimated to the Town Council that he will consent to the use of the telephone ducts in certain streets for the purpose of the underground telegraph wires, although there are serious drawbacks to this course, in view of extensions.

ERITH: *Tramways Intercommunication.*—The Urban District Council, having received from the London County Council a plan showing the proposed temporary terminus of the London County Council tramway at Abbey Wood, is to ask the County Council their reasons for suggesting to make the present terminus at a distance of about 80 ft. from the county boundary, and to point out that it is most desirable for the convenience of through passengers that the tramways of the London County Council and the Erith Council should actually be joined up at the county boundary, as provided by the London County Council (Tramways and Improvements) Act, 1904. The Woolwich

Digitized by Google

Borough Council has also protested against the County Council's proposal with regard to the terminus.

FALKIRK: *Proposed New Tramways.*—A letter has been received by the Council from the Secretary of the Falkirk & District Tramways Co. in regard to the recent request made by a deputation of ratepayers to extend the tramways to Laurieston. The company state that it is impossible for them to construct the extension unless the local authorities are prepared to grant facilities. The tramway undertaking has not been a financial success, owing to the heavy wayleaves and operating charges for bridges, and the directors are unwilling to incur further capital expenditure except upon terms which promise reasonable profit. In return for extending the tramways, the company make certain propositions, including the withdrawal of the wayleaves in respect of the tramways in the borough, and that they be also relieved from local rates in respect of the extension. The Council has unanimously decided that the terms proposed cannot be entertained.

FRANCE: *Electric Cranes.*—The facilities of the port at St. Nazaire are to be increased by the construction on the quay of the Penhouet dock of an electric crane with a lifting power of 180 tons. This crane will be able to lift 180 tons to a height of 145 ft. above the quay level, and take it a distance of 34 yards outside the quay. The arm of the crane will be fitted with another rolling crane of 15 tons lifting power.

HASLINGDEN: *Workhouse Lighting.*—The General Purposes Committee of the Haslingden Guardians decided last week-end to furnish each member with the report of Messrs. Peers, Copeland & Cardin, as to a scheme for the lighting of the workhouse and new infirmary by electricity. At the meeting on April 23rd, the following amended terms for the supply of electricity for the lighting of the workhouse buildings were submitted by the Rawtenstall Corporation. For 15,000 units, 4½d. per unit; for 20,000 units and over, 4¼d. per unit; for 25,000 units and over, 4d. per unit. The Corporation agreed to lay and maintain the necessary cables, and were prepared to enter into an agreement for five years in the first place, subject to termination at any time by six months' notice on either side. It was resolved that further consideration of the matter be deferred until a deputation had met the Corporation's representatives.

LANCASTER: *Tramway Fares.*—A recommendation by the Tramways Committee in favour of halfpenny fares on certain routes, and a penny universal fare on other routes, was negatived at the last meeting of the Town Council in favour of a reversion to halfpenny stages without overlapping.

LEEDS: *Tramway Accounts.*—The accounts for the year to March 31st show a gross profit of £163,051, an increase of £6,470 over the figures of the previous year. Working expenses amounted to £177,317, and out of the balance has to be deducted income tax and interest on capital, leaving a sum of £123,538, from which the following amounts are deducted :—Sinking fund, £37,452; permanent way renewals, £21,252; and amounts written off Provisional Orders, £385; leaving £64,246 to be transferred to the city fund in aid of rates compared with £69,262 in 1907.

LONDON: *St. Pancras: Highgate Hill Tramways.*—In reference to a request by the London Council Council that, in the event of the County Council taking over the Highgate Hill Tramways, St. Pancras Borough Council should undertake to maintain portions of the road in the Borough outside the tramways area, the General Purposes Committee express the opinion that the request should not be acceded to.

Woolwich.—The Law and Parliamentary Committee recommend that counsel be reserved in the House of Lords in opposition to the London and District Electric Supply Bill and the London Electric Supply Bill.

MUSSELBURGH: *Public Lighting.*—The Town Council held a special meeting last week to discuss, with the representatives of the Musselburgh Electric Light & Traction Co., the question of the defective public lighting of the town. The representatives of the company complained that the fault lay with the lamps, which were the property of the Council, and it was not within the province of the company to take these out and put in others. After some discussion, the Council requested the company to submit proposals for the betterment of the existing state of things, and the company's representatives were reminded of the Council's threat to revert to gas lighting.

PLYMOUTH: *Incorporated Municipal Electrical Association.*—Mr. E. G. Okell, the Borough Electrical Engineer, will attend the annual conference of the Incorporated Municipal Electrical Association at Nottingham in June.

Third Party Insurance.—A communication has been received from the Halifax Corporation Tramways Committee inviting the Council to appoint delegates to attend a Conference on third-party insurance with a view to formulating a mutual scheme. It was decided that the members of the Tramways Committee should be notified of the date of the proposed Conference, and that if any of them, or the Town Clerk, should be in London at the time, they might attend as representatives of the Corporation.

RADCLIFFE: *Depreciation.*—It is recommended that the Council should base the charges for depreciation upon the electrical plant in future on the following rates, less the amount of contributions to sinking fund, viz.: Buildings, 2½ per cent.; machinery, 5 per cent.; switchgear, accumulators, meters, motors, and mains, 7½ per cent.

ROTHERHAM: *Electricity Accounts.*—The receipts from the electricity undertaking during the year ended March 31st, 1908, amounted to £13,108, an excess over the previous year of £1,999. The total number of units sold was 1,698,174, representing a gross receipt of 1·652d. per unit. Generation, distribution expenses, rates, and management charges amounted to 0·88d. per unit, compared with 0·87d. for the previous year. After meeting capital charges there is a surplus of £3,302, from which is deducted £1,960 for depreciation and renewals, leaving the sum of £1,342 net profit.

Tramways Accounts.—The gross receipts from the tramways department amounted to £31,653, representing 11·55d. per car mile. There is an increase of £4,737 over the receipts for the previous year. The expenses are considerably higher than those of the previous year, owing to renewals. The traffic expenses amounted to £8,124, and after debiting the whole of the working expenses and repairs there is a balance of £10,330, from which has to be deducted capital charges. The net surplus, subject to provision for renewals fund, is £5,618. The Tramway Manager calculates that the proper sum to be set aside for renewals is £4,898, but inasmuch as in his opinion the sums set aside for the previous years is inadequate, he recommends that the whole of the surplus be retained for this purpose.

SALFORD: *Damages for Tramcar Accident.*—At the Manchester Assizes on Monday a widow named Elizabeth Ball was awarded £200 damages in respect of the death of her husband, who was killed by a Salford Corporation tramcar on November 9th last.

TORQUAY: *Dolter System.*—Mr. Pringle has inspected the Torbay route on behalf of the Board of Trade, and expressed his satisfaction with it.

WALTHAMSTOW: *Charge for Tramway Energy.*—The Council, at its meeting on April 24th, decided, on the recommendation of the Rate Committee, that a charge of 1⅝d. per unit be made to the light railways undertaking for the current consumed for the year ended March 31st last.

TENDERS INVITED AND PROSPECTIVE BUSINESS

AUSTRALIA.—The Board of Trade correspondent at Melbourne (Mr. M. Hirsch) has forwarded particulars of a call for tenders for the supply to the Deputy Postmaster-General at Melbourne of 2,800 jacks in strips of 20; 1 mile of 64-wire switchboard cable; 50 three-conductor cords, 7 ft. long; 96 three-part plugs; and 66 listening and ringing keys. Tenders will be received by the Deputy Postmaster-General, Melbourne, up to 3 p.m. on June 9th.

The Board of Trade are notified by the London representative of the Australian Commonwealth (Capt. R. Muirhead Collins, C.M.G.) that tenders will be received at the office of the Deputy Postmaster-General, Perth, until noon on Monday, September 7th, for the supply of the following telephone material, viz.: 650 wall sets, 150 table sets, 800 protectors, 90 extension switch and bell sets, complete, 30 switchboards for four lines, 20 switchboards for six lines, 5 switchboards for twelve lines, 5 switchboards for twenty-four lines, 20 wall sets for party lines, and 10 table sets for party lines. Tenderers must state the country in which the articles tendered for have been made or produced, and, in the case of manufactured articles, where the material has been made or produced. Tenders must include customs duty, if any. A deposit, equal to 5 per cent. of the amount of the offer, will be required to qualify any tender. Specifications, conditions, and forms of tenders may be obtained at the Commonwealth of Australia Offices in London, 72 Victoria Street, S.W.

Tenders for the following are invited by the Deputy-Postmaster-General, Sydney :—Supply and delivery of eight tons of hard-drawn copper wire (400 lb. per mile), 1½ cwt. of copper tape binding (200 lb. per mile), 1,300 best white large porcelain insulators, and 2,000 tallow-wood crossarms, 5 ft. 2 in., by June 10th, and the supply, delivery, and erection of a branching metallic multiple magneto switchboard by August 12th. Specifications, conditions, and forms of tender may be obtained at the Commonwealth Offices in London, 72 Victoria Street, S.W., where also preliminary deposits on tenders may be paid.

BEDFORD.—Electrical sundries are to be purchased to the value of about £130.

BIRMINGHAM.—A Local Government Board inquiry was held on Tuesday into the application by the Corporation for sanction to borrow £251,285 for extensions to the electricity undertaking. The proposed loan will be split up amongst the power station and sub-station as follows:—Summer Lane station, £183,635; Water Lane station, £17,300; Dale End, £15,000; sub-stations, £14,850. £20,000 is proposed to be utilised for motors, and £4,000 for meters. Under the scheme of extensions, the Dale End station will be abandoned for generating purposes, and converted into a sub-station. At the Summer Lane generating station it is proposed to add a 1,500-kw. direct-current and a 1,500 alternating-current set each year, in order to deal with the gradual development of the load, and in this way it was explained to the Local Government Board inspector that the whole of the money would not be expended at once. Of the total of ten new boilers, however, six will be installed during the current year. A reserve coal bunker, bringing the total storage from 2,000 to 3,000 tons, is also to be erected. It was stated that the generating expenses at Dale End were 2·1d. per unit, against 0·284d. per unit at Summer Lane.

BRIGHOUSE.—A Local Government Board inquiry will shortly be held into an application by the Corporation for sanction to borrow £3,600 in connection with extensions to the electricity undertaking. An arrangement has been made for supply in bulk from the Yorkshire Electric Power Co.

BURNLEY.—A Local Government Board Inspector will hold an inquiry to-morrow relative to the borrowing of £12,500 for public baths, and £26,460 for the purposes of the electrical undertakings.

CHELTENHAM.—Tenders are invited for an electric lighting installation at the new refuse destructor works. Full particulars from the Borough Surveyor, and tendes by May 2nd.

COLNE.—A Local Government Board inquiry will be held to-morrow at the Town Hall into the application of the Corporation to borrow £4,170 for electric lighting purposes.

DARLINGTON.—Tenders are invited for a Lancashire boiler and superheater. Particulars from the Borough Electrical Engineer (fee £1 1s., returnable), and tenders to the Town Clerk by May 11th.

DUNDEE.—The Tramways Manager has submitted a report upon a circular tramway in the town, of an approximate length of 2½ miles. The estimated cost of constructing a double line on the overhead system is put at £28,500, in addition to an allowance for street widenings. The estimated revenue is put at £2,738, and the cost of working and maintenance at £7,690, thus showing a deficit of £4,592. If a single line were made over a somewhat shorter route the cost is put at £10,900, the revenue at £1,870, and the working expenses at £2,149. The report has been circulated amongst the committee, and will be considered at a subsequent meeting.

EAST HAM.—Tenders are invited for the reconstruction for electric traction on the overhead system of the existing horse tramways between High Street North and Green Street, Romford Road, including the permanent way, paving, and overhead line construction. Full particulars from the Borough Engineer, Mr. A. H. Campbell, or the Tramways Engineer and Manager (fee £2 2s., returnable), and tenders to the Town Clerk by May 5th.

ILFORD.—At a Local Government Board inquiry into the application of the Urban District Council to borrow £27,000 for purposes of electric lighting, it was explained that the application was necessitated by the growth of the undertaking. It was mentioned that there are now 3,045 customers, and 1,445 street lamps, and there are 62 oil lamps in the Beehive and Barkingside districts, which are to be replaced and supplemented by electric lamps. The existing machinery was sufficient for present purposes, but next winter the additional plant would be required.

LONDON: *London County Council.*—Tenders are invited for the wiring and fitting for electric lighting of a tramway car shed at Mare Street, Hackney. Particulars from the Clerk, fee £2 2s., returnable, and tenders by May 12th.

Tenders are also invited for the supply and delivery of about 2,000 tons of steel girder tramway track rails and fastenings required for the electrification of further portions of the Council's tramways. The Council also invite alternative tenders for the supply and delivery of about 5,000 tons of track rails and fastenings. Full particulars from the Engineer to the Council (fee, £2, returnable), and tenders to the Town Clerk by May 19th.

Tenders are invited for the supply and delivery of (*a*) 175 double-deck, roof-covered, electric car-bodies; (*b*) 175 pairs of maximum traction swing bolster trucks; (*c*) 175 complete electrical equipments for operation upon the overhead trolley, surface contact, and underground conduit systems of electric traction. Full particulars from the Clerk to the Council (fee £2 2s. returnable), and tenders by May 9th.

Battersea.—In order to cope with the anticipated load in the Nine Elms district next winter, the Lighting Committee report that it will be essential to make some provision for maintaining the pressure by either providing an additional low-tension cable, estimated to cost £8,833, or a feeder, booster, and accessories, estimated to cost £1,847. The committee, although feeling that greater security against breakdowns would be given by provision of the additional low-tension cable, do not see their way to incur the expenditure involved, being of opinion that for the present purposes the smaller scheme will suffice.

Three electric radiators are to be provided and fixed in the dressing-rooms at the Nine Elms Baths at a cost of £18 9s. Application has been made to the L.C.C. for a loan of £8,558 for expenditure incurred in the laying of mains and services for the electric lighting.

Stoke Newington.—A distributor cable is to be laid along the Bethune Road from Fairholt Road to Grange Court Road at an estimated cost of £61. The Finance Committee, at the request of the Electric Lighting Committee, is to negotiate for taking up a further £1,000 of the £5,000 recently sanctioned by the L.C.C. for the extension of mains.

St. Pancras.—An artesian well is to be sunk at the King's Road generating station at a cost of £2,000.

Woolwich.—The Electricity Committee reported at the meeting of the Borough Council on April 23rd that they had received an application for electricity supply for lighting and power "in a district where there is every possibility of obtaining remunerative demand in the near future, especially for power." Mains are to be extended to meet this demand at an estimated cost of £680. The committee reported another application for electricity supply, which it was anticipated would ultimately prove remunerative, "the district being a very promising one, and the premises being situated within the compulsory area of supply included in the second schedule of the Council's 1905 Order." Mains are to be extended to the premises in question at an estimated cost of £131. Tenders are to be obtained for the supply of a motor alternator to the specification of the Borough Electrical Engineer, power being delegated to the committee to accept one of the tenders, subject to subsequent report to the Council.

MANCHESTER.—The Tramways Committee invite tenders for the supply of hard-drawn copper trolley wire. Specifications, &c., from the General Manager, and tenders to the Chairman of the Electricity Committee, 55 Piccadilly, Manchester, by May 5th.

PORTSMOUTH.—Tenders are invited for the wiring and fitting of the laundry at the Infectious Diseases Hospital. Full particulars from the Borough Electrical Engineer, and tenders by May 6th.

A transporter bridge is to be constructed across the Langstone Harbour in connection with the proposed light electric railway to Hayling Island.

RAWTENSTALL.—Tenders are invited for the supply, delivery, and erection of steel tramway poles, overhead line equipment and accessories. Full particulars from the Consulting Engineers, Messrs. Lacey, Sillar, and Leigh, 2 Queen Anne's Gate, Westminster, and 78 King Street, Manchester (fee £3 3s., returnable), and tenders to the Town Clerk by May 4th.

RUGBY.—The Urban District Council invite tenders for 880 yards of paper-insulated lead-covered and armoured service cable. Particulars from the Clerk, to whom tenders by May 5th.

SOUTH AFRICA.—It is stated that the East London Council will shortly invite tenders for an electrical installation, and that particulars may be obtained from Messrs. Dyer & Dyer, 17 Aldermanbury, E.C.

SWANSEA.—The Swansea Harbour Board is considering the question of whether electric or hydraulic power shall be adopted at the new dock, and a committee has been appointed to submit a report.

SWITZERLAND.—The Federal Council recommends the adoption of the following projects, viz.:—(1) The construction of a funicular electric railway, of 1m. gauge, from the Place Léonard, at Zurich, to Susenberg (Zurichberg), a distance of 1,614 metres; (2) the construction of an electric railway of 1m. gauge, partly cogged, from Brigue to Belalp, a distance of 11,700 metres.

SPAIN.—A public competition will be held at the Junta de Obras (Board of Works) of the port of Tarragona, at 5 p.m. on May 31st, for the purpose of adjudicating the contract for an electric installation for lighting and motive power at that port. Tenders will be received up to the time of the adjudication. Local representation is necessary.

WAKEFIELD.—The West Riding and Yorkshire Rivers Board invite tenders for two exhaust electrical fans, switches, &c., for their laboratory at Wakefield.

WALTHAMSTOW.—The Urban District Council has received from the Local Government Board sanction to the borrowing of £17,189 for the provision of additional plant at the generating station, and £222 for an air compressor and weighbridge.

WEDNESBURY.—The Local Government Board has sanctioned a loan of £8,000 for the purpose of a generating station. Hitherto the Council has taken a supply in bulk from the Midland Electric Corporation for power distribution, but owing to the price being too high to allow of the undertaking being made remunerative, the agreement has been cancelled.

TENDERS RECEIVED AND ACCEPTED

ADMIRALTY.—Messrs. Vickers, Sons & Maxim, Ltd., on behalf of the Admiralty, have ordered from the British Thomson-Houston Co., Ltd., 21 motor-generator sets, each giving 120 amps. at 55 volts (6·6 kw.) 1,600 r.p.m., with the necessary control panels. These are to operate searchlights on board H.M.S. *Vanguard*, a battleship of the *St. Vincent* class, which Messrs. Vickers, Sons & Maxim are building.

The British Thomson-Houston Co., Ltd., are also supplying nine motor generators (8–120 amp. and 1–80 amp.) for operating searchlights on H.M.S. *Defence*.

DARLINGTON.—The tender of the British Thomson-Houston Co., Ltd., has been accepted by Messrs. Pease & Partners, Darlington, for plant to be installed at Bowden Close Colliery :—One 120 h.p. 480 r.p.m. 440-volt 40-cycles three-phase slip-ring protected-type haulage motor, with tramway-type reversing controller and panel; one 25 h.p. 770 r.p.m. fan motor; one 150 kw. three-phase 2,750/440-volt oil-cooled transformers, with the necessary switchgear.

HUDDERSFIELD.—Messrs. Joshua Whiteley & Co., Ltd., have placed a contract for the complete electrical equipment of their "Albert" textile mill with the British Thomson-Houston Co. The installation consists of 23 three-phase induction motors totalling upwards of 800 h.p., with the necessary steel work for mounting the ceiling-motors, and controlling gear and cables. This is the first textile mill to be electrically driven from the Corporation three-phase mains in the Huddersfield district, which is one of the main centres of textile industry. This contract should be as far-reaching in its influence on the development of textile driving in this district as the Acme mill has been in Manchester.

JOHNSTON (N.B.).—The British Thomson-Houston Co., Ltd., are supplying to Messrs. Finlayson, Bousfield & Co.'s linen-thread mills a 200 kw. 428 r.p.m. 500–550-volt 50-cycle three-phase alternator, with three pedestal bearings, protection caps, rope pulley, base plate, and direct-coupled exciter, together with the necessary switchgear.

LONDON: *Battersea.*—The Lighting Committee recommend the acceptance of the tender of the Lancashire Dynamo & Motor Co., Ltd., to provide feeder booster, switchgear spares, &c., at £1,502 4s., the Council to carry out the work of providing foundations, cable, &c., at an estimated cost of £545.

Hammersmith.—Messrs. Gwynnes, Ltd., have ordered the following plant from the British Thomson-Houston Co., Ltd., viz. :—A testing plant, consisting of a 120 kw. motor-generator set, made up of two 60 kw. C.C. generators, tandem-coupled to one induction motor, one 110 k.v.a. three-phase motor-generator, and a motor exciter of 10 kw.

Metropolitan Asylums Board.—The following tenders have been received for the installation of electric lighting, &c., at the South-Western Hospital and Ambulance Station :—W. J. Fryer & Co. (accepted), £3,434; Electrical Co., Ltd., £3,700; G. E. Taylor & Co., £3,787; H. J. Cash & Co., Ltd., £3,819; W. Barton & Sons, £3,825; H. & C. Davis & Co., Ltd., £3,833; J. S. Anderson, £3,900; Tamplin & Makovski, Ltd., £3,926; Lund Bros. & Co., £3,980; C. Pullan, £4,027 16s.; Tilley Bros., £4,095; Pinching & Walton, £4,157 12s.; G. Weston & Sons, £4,368; A. Hawkins & Sons, £4,475; Perry & Co., £4,486; W. G. Cannon & Sons, Ltd., £4,560 10s.; A. Arthur & Ure, £4,685; H. J. Godfrey, £4,735; Wenham & Waters, Ltd., £4,741; T. Potter & Sons, Ltd., £4,866; A. C. Smith, engineers (Lincoln), Ltd., £4,956 16s.; F. A. Glover & Co., Ltd., £5,700; Laing, Wharton & Cunnington, £5,750; J. H. Taylor & Co., £5,899; Cox-Walkers, Ltd., £5,995. Engineer-in-chief's estimate, £4,000.

St. Pancras.—The Electricity Committee has provisionally accepted the following tenders for the supply of coal at the generating stations: Charrington, Sells, Dale & Co., 600 to 800 tons "Babbington" large hard steam coal at 16s. 3d. per ton; Spenser Whatley, Ltd., 600 to 800 tons "Desford" steam cobbles at 14s. 11d. per ton.

Woolwich.—The Borough Council has received the following tenders for the supply of oil eliminating plant to the Plumstead Electricity Works :—Atkins Filter Engineering & Water Softening Co., £90; Stanhope Water Engineering Co., Ltd., £160, time for delivery, 7 weeks; Harris Patent Feed Water Filter, Ltd., £175, 10 weeks; Babcock & Wilcox, Ltd., £200, 8 weeks; Paterson Engineering Co., Ltd., £200, 2–3 weeks; Wm. Boby, (a) £204, (b) £209, 7 weeks; Davis-Perret, Ltd. (accepted), £299 15s., 4–5 weeks.

The Borough Council has also received nine tenders for the supply of motors, viz., (a) 50–3 amp. size, (b) 50–5 amp. size, (c) 50–10 amp. size, (d) 25–25 amp. size, (e) 25–50 amp. size, (f) electrolytic type of motor, (g) period of guarantee, 5 years. The tender of Messrs. Chamberlain & Hookham has been accepted at the following prices :—(a) £1 16s.; (b) £2; (c) £2 5s.; (d) £2 10s.; (e) £2 14s.; (f) Mercury motor type; (g) 3 years. The total amount of the tender is £452 10s. Tenders by Messrs. Marples, Leach & Co., the Electrical Co., and Siemens Bros., the Electricity Committee point out, were for motors of foreign manufacture, which had not yet received the Board of Trade's approval. The motors to be supplied by Venner & Co. (for Chamberlain & Hookham) were of a new type, and had not, of course, had an extended trial. Large numbers of the same manufacturers' old-type motors were in circuit in the Borough, and gave every satisfaction, but the manufacturers claimed further advantages for their new type. In considering the tenders, the Committee paid due regard to the question of price in relation to the merits of the respective meters, and from previous experience they were convinced that motors of substantial design were the cheapest in the end.

SHEFFIELD.—The Sheffield Coal Co. have recently placed contracts for the following plant for their Birley Collieries, near Sheffield, with the British Thomson-Houston Co., Ltd. :—One 250 kw. 375 r.p.m. 3,000-volt 50-cycle three-phase B.T.-H.-Belliss generating set; three-panel main switchboard; five sets of main and tail haulages (two 30 and three 50 h.p.); two motor-driven pumps (30 and 80 h.p.); one 100 kw. and two 70 kw. transformers, and high-tension and low-tension panels.

Messrs. D. Selby Bigge & Co. have ordered from the British Thomson-Houston Co., Ltd., for Earl Fitzwilliam's Colliery, Elsecar, near Sheffield, a 350 kw. exhaust steam turbo-alternator, with heat accumulator, condenser, and the requisite switchgear.

STALYBRIDGE, HYDE, &c., ELECTRICITY BOARD.—The following tenders have been received for a 2,000 kw. turbo-alternator and condensing plant :—Messrs. C. A. Parsons & Co., Ltd., £7,900; Messrs. Willans & Robinson, Ltd., £8,250 (accepted).

TAMWORTH.—The following plant is being supplied by the British Thomson-Houston Co., Ltd., to Messrs. Morris & Shaw, Ltd., Birch Coppice Colliery, Polesworth, near Tamworth :—Main switchboard, pit-bottom and feeder panels; one 75 h.p. three-phase motor for driving endless haulage gear, the requisite feeder cable.

WARWICKSHIRE.—The British Thomson-Houston Co. is supplying to the Ansley Hall Coal & Iron Co., Atherstone, Warwickshire, a 500 kw. 340 r.p.m. 500-volt compound-wound open-type C.C. generator, to be driven by ropes by a pair of Robey engines running at 85 r.p.m., with the necessary switch panels.

COMPANIES' MEETINGS AND REPORTS

BABCOCK & WILCOX.—At the annual general meeting last Friday the report and accounts given in our last issue were adopted. Mr. John Dewrance, the Chairman of the company, who presided, referring to the large balance available for disposal, viz., £266,264, said that this appeared to be a considerable proportion compared with the company's capital, but a perusal of the balance-sheet showed that, owing to the conservative policy which had always been adopted, the nominal capital was really very small in proportion to the total assets, and therefore the profit was really not a very large one upon the company's trading. He regarded the satisfactory result as being due to the magnificent organisation which the company had throughout the world, which enabled them to make a profit on prices which their competitors could not touch. In a brief reference to the Eight Hours' Bill the Chairman said that this legislative attempt to restrict the output of coal would stimulate an enormous amount of commercial disturbance, probably with strikes in all parts of the country, which could not fail to have a serious effect upon the company, as well as upon others. There had been instances of these dangerous legislative threats being shelved, and he hoped this would be the case with the Eight Hours' Bill.

BRITISH ALUMINIUM.—At the annual general meeting on Friday the report and accounts given in our last issue were adopted. Mr. J. D. Bonner, who presided, stated that the result of the year's working, having regard to the derangement of the metal markets throughout the world, which followed the collapse in copper last June, must be considered very satisfactory. The company had contracts for deliveries extending to 1910, and contracts for further large quantities were being completed on the basis of current prices. Whilst it was clear that they would in future have to be content with a smaller percentage of profit, there was every indication that their sales would greatly increase. Now that their works at Stangfjord, and their temporary works at Kinlochleven, were at work, it was anticipated that their output by the middle of this year would

Digitized by Google

be twice what it was last year. They did not expect, however, to have any power available at their Orsières works until after the end of next year.

CATHCART DISTRICT RAILWAY.—At the meeting last week, the chairman stated that in order to counteract the serious competition of the Glasgow Corporation Tramways, the company had introduced zone tickets available for any number of journeys.

CITY OF BIRMINGHAM TRAMWAYS.—At the annual meeting on Thursday, the report and accounts given in our last issue were adopted. Mr. Emile Garcke (chairman), who presided, said that nothing had happened during the past year that was not anticipated, in a very large degree, some years ago. They had lost some of their lines at the end of December, 1906, and the resultant loss of traffic during the past year has been £124,000. The net profits, however, were only £43,359 less than in the preceding year, showing that the expenses of working had been reduced in the same proportion as the receipts. The shrinkage in the receipts had, as a matter of fact, been less than anticipated, as the result of losing the lines, which reverted to the Corporation at the end of 1906, and this notwithstanding the fact that they had been exposed to very severe competition by the Corporation's new electric tramways. The Board had been occupied during the past year in conducting negotiations for the realisation of the remaining assets, and at the present time accumulated redemption funds for the redemption of debentures and an investment fund which, with cash and other assets of a liquid nature, amounted to an aggregate of £552,610. The total paid up capital was £284,000, the debentures were £300,000, and sundry creditors amounted to £32,000, or a total of £616,224, so that their liquid assets stood at a total very nearly approaching the total amount of their paid up capital and obligations. The investments, however, included an investment in the Birmingham and Midland Motor Omnibus Company, standing at £50,000, which he was sorry to say is not likely to produce its full value. Taking it altogether, however, he thought the financial position of the company was satisfactory. The assets still to be realised were the Bristol Road Tramways and the Cable Tramway until the year 1911, which represented 4¼ miles, and 7½ miles of tramways outside the city, some of which belong to the company, and are not purchasable by the local authorities until the year 1936. There was also the working of the lease of the Aston Corporation Tramways, which, however, were not yielding any profit at present to the company. Touching upon the question of whether it would be advisable to carry on the operations of the company in future under the powers of a liquidator, the chairman stated that various negotiations which have still to be carried on with local authorities are of such a nature that it was not advisable to put the company into liquidation at present. Moreover, so long as they were able to earn more than 4 per cent. on their investments, there was no direct economic advantage in liquidating the company merely for the purpose of redeeming the debentures, upon which they paid interest at the rate of 4 per cent. per annum. The average yield on the company's investments during the past year was about 5¼ per cent.

WEST COAST OF AMERICA TELEGRAPH.—The report for the year ended December 31st, 1907, shows gross receipts amounting to £61,854, as against £68,048 in 1906. The working expenses were £34,616, as compared with £34,173 for the previous year. After providing £6,000 for the interest on the 4 per cent. debentures, £800 for the interest on the 4 per cent. income bonds, and £193 for income tax, there remains a balance of £20,245, to which is added the sum of £1,923, brought forward from December 31st, 1906, making a total of £22,168. Of this amount £16,000 has been placed to the general reserve fund, and £2,000 to the maintenance ship's reserve fund, and the directors recommend the payment of a dividend of 2½ per cent., free of income tax, amounting to £2,813, leaving a balance on the revenue account of £1,355 to be carried forward to the next account. The meeting is to-day.

CRAIGPARK ELECTRIC CABLE.—The report for the year ended March 31st shows a profit of £7,128, to which is to be added £604 brought forward from last year. The directors recommend the allocation of £1,000 to depreciation of buildings and machinery. A dividend upon the 6 per cent. preference shares for the half-year to September 30th, 1907, and to the half-year ending March 31st, 1908, has been paid, and a dividend of 6 per cent. upon the ordinary shares for the twelve months ended March 31st, 1908, is now recommended, together with a transfer of £1,000 to reserve account, and £1,232 to be carried forward. The report states that in the cable department of the company the business shows a satisfactory increase in spite of the general depression in trade. Prices of raw materials are more favourable, and the directors look forward with confidence to the coming year.

DUDLEY, STOURBRIDGE & DISTRICT ELECTRIC TRACTION.—At the annual general meeting on Thursday, Mr. A. C. Miles presiding, the report and accounts given in our last issue were adopted. The Chairman pointed out that in spite of the reduction in the number of passengers carried during the year of 130,000, the receipts had been maintained at 11d. per car mile. One reason for the reduction in the amount to be distributed was that the directors had allocated a sum of £2,000 for renewals. The directors deplored the result of the appeal case before the House of Lords in respect of Light Railway No. 5, as in consequence the company was receiving about £16,000 less than if the undertaking had been purchased under the Light Railway Act. It was the intention of the Board to utilise the purchase money of the tramway in question for acquiring the Kinver Light Railway. The centralisation of the workshops for the whole system at Tividale had led to great economies, and further economy was anticipated by the agreement with the Shropshire, Worcester & Stafford Electric Power Co., for a supply of electrical energy.

THE ELECTRIC TRACTION CO. OF HONG KONG.—The report for 1907 shows a profit of £5,950, after paying debenture interest and other charges. With the amount brought forward from the last accounts, the available balance is £6,530. Of this the directors have placed £6,000 to reserve for depreciation and renewals, carrying the balance of £530 forward. The reserve for renewals fund now stands at £12,000. A loss of £4,000 is reported in respect of subsidiary coinage, and the report states that unless some definite step is taken at an early date to mitigate this evil the Board would have to consider the question of raising the fares.

INDO-EUROPEAN TELEGRAPH.—The report for the year ended December 31st, 1907, states that the company's revenue from message account and other sources amounts to £136,579, as compared with £124,610 for 1906, showing an increase of £11,969. The expenses are, on commercial and general account £47,618, and on maintenance account £25,434, making a total of £73,052, as against £73,642 for 1906, showing a decrease of £590. The revenue account therefore shows a balance of £63,526, which is carried to profit and loss account, 1907, and after deduction of income-tax paid is reduced to £60,228. To this is added the balance of profit for 1906 brought forward of £8,974, making a total of £69,203. The sum of £18,144 has been provided to meet the further depreciation to date, which has unfortunately taken place upon the company's investments, and a small loss in connection with the redemption of certain of the same. Deducting this sum and the interim dividend of £10,625 already paid, there remains a balance available for distribution of £40,433. The directors now propose to declare a dividend for the six months ended December 31st, 1907, of 17s. 6d. per share (making with the interim dividend already paid, 6 per cent. for the year) and a bonus of 20s. per share, both free of income-tax, carrying forward £8,558. It is also proposed to make a special distribution to the shareholders of £12,750, equivalent to 15s. per share, out of interest upon certain investments. For this purpose a small sum from the interest accrued during 1907 upon the equalisation of dividends fund investments has been added to the interest (for the year 1907) upon unappropriated investments and upon the deposit of Russian Government Rente, from which sources a similar distribution was made last year. At the meeting on Tuesday the report and accounts were adopted.

JOHNSON & PHILLIPS.—The report for the year ending 1907 shows a net profit, after making provision for bad and doubtful debts, and charging to revenue £4,300 for maintenance and building plant, &c., of £31,530, to which is added a balance of £11,451 brought forward from 1906, making a total available of £42,981. A dividend of 7 per cent. per annum upon the ordinary shares is recommended, transferring £8,000 to reserve, and carrying forward £6,873. At the meeting on Monday, when Mr. R. W. Blackwell, Chairman, presided, the report and accounts were adopted. In his speech the Chairman said that the principal thing he would like to call attention to was that at the present moment the business of the company, being centred in general telegraphic and submarine work, and in the working of india-rubber, and in the manufacture of cables, they had been able to a large extent to escape the great troubles met with by purely electrical engineering manufacturing firms. The new works which had been started early last year had been entirely completed and fully occupied during the past year. In view of the very considerable price which the company had to pay for electric power, the directors were very glad to notice that steps were being taken to obtain Parliamentary powers, which would provide something in the nature of a bulk supply for London. At the present moment they were practically depending upon one supply, and any breakdown in the station would be a very great disadvantage.

KALGOORLIE ELECTRIC POWER & LIGHTING.—The report for 1907 states that the amount of power sold during the year constitutes a record. The increase in the profit, although not in proportion to the increase of electricity sold, was nevertheless considered satisfactory, the gross profits for the twelve months being £26,597. Reconstruction and registration expenses, and the issue of debentures reduces this total to £22,010, out of which debenture interest, preference share dividends, reserve for depreciation and renewals, and dividend tax in Western Australia leave a balance of £5,330 to be carried forward. The directors recommend a dividend of 5 per cent. per annum on the ordinary shares for the six months ending June 30th, 1908. Since the date to which accounts have been made up a dividend has been declared upon the preference shares for the six months ending March 31st, 1908, of 6 per cent. per annum.

KALGOORLIE ELECTRIC TRAMWAYS (WESTERN AUSTRALIA).—The report for the year 1907 shows gross receipts of £48,008, compared with £51,379 for the previous year. The

Digitized by Google

net profits are £16,270, compared with £17,546. The falling off is attributed to the reduction in the number of men working in mines, in consequence of the increased use of labour-saving machinery. During the year 650,530 car miles have been run, and 3,052,241 passengers carried, the respective figures for the previous year being 673,544 and 3,220,728. The number of units sold in 1907 was 930,231, compared with 933,109. The revenue per car mile in 1907 was 17·63d., and the expenses 11·17d., against 18·22d. and 11·31d. respectively. The percentage of expense to revenue in 1907 was 63·36 per cent., compared with 62·24 for the previous year. Owing to the depression in the money market the directors have been able to redeem a larger amount of debenture stock than was anticipated. The meeting will be held on May 6th.

KIDDERMINSTER AND DISTRICT ELECTRIC LIGHTING AND TRACTION.—The report and accounts for the year 1907 shows that the total capital expenditure to December 31st, 1907, on account of buildings and plant for electric supply amounted to £50,798, an increase of £5,023, which is chiefly due to the installation of the new 500 kw. generating set and auxiliary plant. The gross receipts, including the amount receivable from the Kidderminster and Stourport Electric Tramway Company for dividend on the shares held by this company, amount to £9,388, which, added to £687 brought forward from last account, makes £10,075. After deducting the expenses (including debenture stock and loan interest), amounting to £5,861, there remains a balance of £4,214. The directors propose that £750 should be placed to depreciation and renewals fund; debenture and loan redemption reserve, about £500; dividend on cumulative preference shares for the year 1907, £1,500; a 2½ per cent. dividend on the ordinary shares, £1,175; leaving £289 to be carried forward. After the above appropriation has been made, the balance of the sums reserved to date out of revenue by this company and the tramway company for the purposes shown in the accounts is £6,395.

Attached to the report is a copy of the balance sheet and profit and loss account of the Kidderminster and Stourport Electric Tramway Company for the year ended December 31st, 1907. The gross receipts amount to £6,335, being a decrease of £18 as compared with 1906, and the expenses to £3,268, an increase of £67. The profit on the year's working is £3,066, which, added to the balance of £39 brought forward, makes a total of £3,105 at the credit of profit and loss account. This amount has been applied as follows :—To reserve and renewals fund, £500; 4½ per cent. on the ordinary shares, £2,574; carrying forward £32. The demand for electrical energy for lighting and power purposes continues to increase satisfactorily, the connections in 8 c.p. lamps, including traction, having increased from 37,667 in 1906 to 47,814 during 1907. The total number of Board of Trade units sold in 1907 was 1,042,204, as compared with 705,841 during the preceding year, while the profit from the electrical supply business shows an increase of £795. The new 500 kw. generating set was first run on load on November 24th last, and, owing to its efficiency being higher than that of the older machines, a further substantial reduction in the casts per unit generated should be obtained during the current year. The company has joined the British Electrical Federation. The following particulars of the tramways are given in the report :—Miles open : 1907—route miles 4·60, single line 4·31, double line 0·29; number of passengers carried, 793,217; average traffic receipts per passenger, 1·84d.; average expenditure per passenger, 0·98d.; proportion of expenses to receipts, 53 per cent.; number of cars in stock, 13. The meeting will be held in London to-day.

LYMINGTON ELECTRIC LIGHT & POWER.—The report for the year 1907 states that the total connections have increased from the equivalent of 15,105 to 16,787 8-c.p. lamps. Including a balance of £154 brought forward, there is a profit of £1,550, from which has been deducted interest on debenture and loans amounting to £574. The directors recommend that £500 be placed to the credit of reserve account, and that a dividend of 5 per cent. per annum be paid on the preference shares, carrying forward £154. At the meeting last week the report and accounts were adopted.

MARCONI'S WIRELESS TELEGRAPH.—The report and accounts for the year ended September 30th, 1907, are given on page 665.

MELDRUM BROS.—The accounts for 1907 show a loss of £6,655. The loss last year amounted to £7,884, thus making a total debit balance of £14,539.

MERTHYR ELECTRIC TRACTION AND LIGHTING.—The report and accounts for the year ended December 31st, 1907, shows a total capital expenditure of £107,288. The directors have had under consideration the question of making provision for the cost of renewals other than those ordinarily charged against the year's revenue, and have accordingly debited the profit and loss account with £1,000, to be placed to a renewals provision account. The gross receipts on the light railways for the year amounted to £11,265, and the gross receipts on account of electrical supply to £5,873, making with £206 sundry receipts, a total of £17,344. After deducting all expenses chargeable to revenue, including £2,056 for debenture interest and placing £1,000 as mentioned above to a renewals provision account, there remains a surplus of £4,347, making with the amount brought forward a total of £4,785. The payment of the dividend on the preference shares for the twelve months ended October 15th, 1907, amounting to £1,500, reduces this sum to £3,283, which the directors recommend should be applied as follows :—Depreciation and reserve account, £1,250; 5 per cent. dividend on the ordinary shares, £1,500; carrying forward £533. £263, the cost of renewing plates in the battery, has been charged against the renewals provision account. The results from the year's working of the electric supply undertaking continue to show satisfactory progress. The gross receipts amounted to £5,872 and the expenditure to £2,103. The receipts for 1907 exceeded the receipts for 1906 by £1,089, while the expenditure was £183 less. The installations (exclusive of the light railways) connected to the mains on December 31st, 1907, represented the equivalent of 18,602 8-c.p. lamps compared with 13,097 for the previous year. The gross receipts from the light railways show an increase of £626 and the expenditure an increase of £336. The Board of Trade has granted a further extension of time for two years from May 16th, 1907, for the construction of the half-mile of line in Cefn. The Merthyr Tydfil Corporation has not yet constructed a new bridge across the river, and until this is carried out the company cannot proceed with the work of laying the lines. The company has joined the British Electrical Federation. The following particulars are given in the report of the light railways :—Miles open : 1907—route miles 2·98, single line 2·02, double line 0·96; number of passengers carried, 1,974,204; average receipts per passenger, 1·41d.; number of cars in stock, 16. At the meeting on Monday the report and accounts were adopted.

OLDHAM, ASHTON & HYDE ELECTRIC TRAMWAYS.—At the annual general meeting on Wednesday the report and accounts given in our issue for April 16th were adopted. Mr. E. Garcke, the Chairman, who presided, said that the passengers carried during the year were 200,000 more than during the preceding year, an increase of about 4 per cent.

PRIMITIVA GAS & ELECTRICITY.—At the annual general meeting on Tuesday the report and accounts given in our last issue were adopted. The chairman, Mr. H. E. Jones, said that in consequence of the arrangement between the Buenos Aires municipality and one of the large electric traction and lighting companies in the city, by which at the end of fifty years the whole of that company's undertaking would revert to the Corporation, a similar proposal had been made to them, but there were certain clauses in the proposed agreement which they did not feel able to accept, and they had declined to be bound by the terms proposed.

SWANSEA IMPROVEMENTS AND TRAMWAYS.—The report for the half-year ended December 31st, 1907, deals first with the tramways undertaking. The directors have had under consideration the question of provision for expenditure on renewals and reconstructions as distinguished from ordinary repairs and maintenance, and they have decided in addition to the depreciation and reserve fund to build up out of each year's revenue a fund to be available for defraying or equalising the cost of extraordinary renewals of the permanent way and plant and equipment. They have accordingly set aside out of the year's profits the sum of £2,500 for this purpose. The gross receipts amount to £27,817, being an increase of £2,741 upon the corresponding period of the previous year. After deducting all expenses chargeable to revenue, including debenture and other interest and the amount payable to the Swansea Corporation in respect of the tramways and light railways leased from the Corporation, and after charging profit and loss account with the sum of £2,500 for provision for renewals as stated above, there remains a surplus of £5,288. The addition of the sum of £3,443 brought forward from last account brings the available balance up to £8,731, out of which the directors recommend the allocation to reserve and depreciation fund of £2,000, and the payment of dividends of 6 per cent. and 5 per cent. per annum upon the preference shares, and 3 per cent. on the ordinary shares, leaving a balance to be carried forward of £1,532. The results for the half-year show material improvement as compared with the corresponding period of 1906. The increased receipts are mainly due to the operation of the revised scale of fares which was put into force on July 1st. The expenses show an increase of £801, which is due to the payment of higher rates of wages to employees, to the increased cost of fuel, and to increased expenditure on repairs and maintenance. The expenditure on capital account during the half-year amounted to £879, including £240, the instalment due in respect of the purchase of cars. During the half-year the liability of the company to sundry creditors has been reduced by £4,183, of which amount £3,500 was carrying a high rate of interest. The company has joined the British Electrical Federation which has been formed by various electric traction and lighting companies for the purpose of co-operation and joint action in matters of common interest. At the meeting on Tuesday the report and accounts were adopted.

TYNEMOUTH & DISTRICT ELECTRIC TRACTION.—The report for the year ended December 31st, 1907, states that the total revenue for the year amounted to £12,847, and after deducting all expenses chargeable to revenue, including repairs and maintenance, interest on debentures and loans, and a sum of £573 which has been placed to provision for renewals, there remains a balance of £4,235, which, added to the amount of £372 brought forward from last account, leaves an available balance of £4,607.

Digitized by Google

The directors have had under consideration the question of making provision for the cost of renewals other than those ordinarily paid out of revenue, and have accordingly debited the profit and loss account as already mentioned, with £573 to be placed to provision for renewals, and recommend that the available balance be dealt with as follows :—To depreciation and reserve account, £500; to capital redemption fund, £500; dividend of 5 per cent. per annum on the cumulative preference shares to December 31st, 1907, £1,525; and dividend of 4 per cent. per annum on the ordinary shares to December 31st, 1907, £1,856; carrying forward £226. The capital expenditure during the year amounted to £88, making the entire capital outlay of the company to December 31st, 1907, £93,501. Having regard to the bad weather experienced continually throughout the year and the depression in the shipbuilding industry on the North-East coast, the directors consider that the result of the year's working is satisfactory. The undertaking has been maintained in good working order and repair. The work of re-roofing ten of the cars with teak and the renewal of staircases and seats has just been completed. A small proportion of the work was carried out before December 31st last, and the cost charged to revenue. Having regard to recent contracts entered into by the Tynemouth Corporation for the supply of current to other lesser consumers on more favourable terms and to other considerations, the company have made representations to the Corporation with a view to a reduction in the price charged to the company. The company has joined the British Electrical Federation. The following statistics are given :—Miles open : route miles 4·21, single line 0·59, double line 3·62; number of passengers carried, 2,060,808; average traffic receipts per passenger, 1·45d.; average expenditure per passenger, 0·86d.; proportion of expenses to receipts, 58 per cent.; number of cars in stock, including water car, 22. The meeting is to-morrow.

WOLVERHAMPTON & DISTRICT ELECTRIC TRAMWAYS.—At the annual general meeting on Thursday the report and accounts given in our last issue were adopted. Mr. S. R. Blundstone, who presided, said that the reason for the profit available being apparently £1,000 less than for the previous year, was that the Directors had allocated the sum of £1,000 for renewals before arriving at the profit. He thought it was satisfactory that the number of passengers had increased by 28,000, in view of the fact that trade was very bad in the district.

THE BRITISH WESTINGHOUSE ELECTRIC & MANUFACTURING CO.—The annual report for the year ending December 31st, 1907, is given on page 664.

PARLIAMENTARY INTELLIGENCE

PROGRESS OF ELECTRICAL BILLS.—In the House of Commons on Monday the Motherwell Burgh Extension and Wishaw Borough Electricity Bills were read a third time.

APPOINTMENTS AND PERSONAL NOTES

The Glasgow Tramways Committee recommend the following increases in salaries in the Tramways Department :—Mr. James Dalrymple, General Manager, from £1,000 to £1,100 per annum; Mr. L. Mackinnon, traffic superintendent, from £575 to £600 per annum; Mr. J. Ferguson, chief engineer, £575 to £600 per annum; Mr. J. N. Wilson, from £325 to £350 per annum; Mr. E. T. Goslen, electrical engineer, from £475 to £550 per annum.

Mr. Patrick Hamilton, formerly Manager of the Electrical Department of Messrs. Kelvin and James White, has joined the board of directors of Messrs. Everett Edgcumbe & Co., Ltd. Mr. Hamilton, who will take an active part in the supervision and design of Messrs. Everett, Edgcumbe & Co.'s various products, and in the management of the business generally, will be located chiefly at the company's Westminster offices, 87 Victoria Street, London, S.W.

MISCELLANEOUS CITY NOTES

LONDON ELECTROBUS.—We give in this issue the prospectus of the London Electrobus Co., from an advance copy of which we gave some extracts last week.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—The proposed scheme for dealing with the profit-sharing notes which fall due in June, published in our issue for April 16th, is now being offered to the holders of the notes in question. The *Times* correspondent in New York, telegraphing last week, states that the scheme has been well received by American holders, and it is believed that the plan will go through promptly.

KAMINISTIQUIA POWER CO. (MONTREAL).—Subscriptions have been invited during the week at 97 for $1,325,000 first mortgage 30 year 5 per cent. gold bonds. The bonds are secured by trust mortgages in favour of the Royal Trust Co. The share price is equivalent to £99 13s. 3d. per bond of $500 or £102 14s. 10d.

NORTH-WEST LONDON RAILWAY CO.—It is stated that an issue of ordinary stock will be made in about three weeks' time, and that shareholders will be entitled to free season tickets in proportion to the amount of stock allotted to them.

700 H.P. SINGLE-PHASE LOCOMOTIVE FOR THE SEEBACH-WETTINGEN RAILWAY

THIS railway, which was electrically equipped by the Oerlikon Co., in the year 1905, has a total length of track of about 15 miles, and deals chiefly with goods traffic. The first locomotive in use on the railway was of the Ward-Leonard type, and contained, besides the transformer and driving motors, an asynchronous motor generator set. The second locomotive was equipped with two 200-h.p. Oerlikon single-phase series-commutator motors, each geared to two of the four axles.

The third locomotive, which was described recently in *Elektrische Kraftbetriche und Bahnen*, and which commenced operation in October of last year, was built by the Siemens-Schuckertwerke. This locomotive is constructed with two three-axle bogies, and is equipped with four 175 h.p. 15-cycle single-phase series-commutator motors of the type described in ELECTRICAL ENGINEERING, Vol. II., page 367. The motors are geared to the axles with a gear ratio of 3·72, corresponding to a speed of 46 miles per hour at rated load. Artificial ventilation is provided for the motors, which, it is stated, have a capacity of 175 h.p. when not artificially ventilated, and 225 h.p. when ventilated. These motors are totally enclosed, but gauze-covered openings are provided for the entrance and exit of the cooling air. The excitation and compensating windings are wound in semi-closed slots in the stator core, the compensating winding producing the necessary commutating field. The rotor winding consists of former wound coils in open slots. The locomotive is provided with two bow collectors and two finger collectors of the Oerlikon type. The two transformers, each of which has a capacity of 500 kw., transform down from the contact-line pressure of 15,000 volts to the motor pressure of from 150 to 380 volts. The transformers are oil cooled, and are situated in a special compartment in the locomotive. There are nine running positions of the controller. The current for operating the contactors is obtained from a low-voltage tapping on the secondary winding of the main transformer. The total weight of the locomotive equipped with four of the 175-h.p. motors is 68 tons. There is room for two more motors on the remaining two axles, and with such a six-motor equipment the total weight would be 75 tons.

CATALOGUES AND PAMPHLETS RECEIVED

IGNITION ACCUMULATORS.—A new price list of ignition accumulator has been issued by Accumulator Industries, Ltd., of 4 White-street, Moorfields, and Maybury, Woking. These cells are fitted with positive plates of an improved Planté type, and the negative plates consist of a special form of porous lead, contained in an under-cut grid. A special feature is the discharge indicator, which can be fitted to any of the cells, consisting of a tube visible from the front of the cell containing four coloured glass beads, to which the acid has free access. These beads are calculated to float only at a certain specific gravity, which corresponds to the condition of the cell.

POWER SUPPLY.—The Loughborough Corporation Electricity Department have prepared a pamphlet, which they are just issuing, calling attention to the advantages of electrical driving, and giving a number of examples of costs of running to show the saving that may be obtained as compared with other forms of power, and containing a list of the principal power consumers on the Corporation mains. It is intended to send out two follow-up letters after intervals in connection with the pamphlet.

TIME SWITCHES.—A leaflet from Messrs. Venner & Co., of 6 Old Queen Street, S.W., illustrates a special form of the "Venner" time switch for incandescent street lighting, arranged in a compact iron case. The working of this switch was described in ELECTRICAL ENGINEERING, Vol. I., page 730.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night was £59 to £59 10s. per ton (last week, £59 10s. to £60 per ton).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Creditors of the Monobloc Accumulator Syndicate, Ltd., are requested to send in particulars of their claims to the liquidator, Mr. H. Newton-Smith, 37 Walbrook, London, E.C., by May 30th.

The Kevan Electric Co., Ltd., is to be wound up voluntarily. Creditors are requested to send particulars of their claims to the liquidator, Mr. Edmund Heisch, 120 Fenchurch Street, London, E.C., by June 3rd.

Kevan Signs, Ltd., is to be wound up voluntarily. Mr. Edmund Heisch, 120 Fenchurch Street, London, E.C., is liquidator.

Digitized by Google

NEW COMPANIES

ELECTRIC BATTERIES AND CARBONS.—This company was registered on April 24th, with a capital of £20,000 in £1 shares, to acquire and turn to account any patents, brevets d'invention, concessions, and the like, conferring an exclusive right to use any invention by F. J. Gerard and L. Fiedler, and to carry on the business of engineers, electricians, manufacturers of electric accumulators, electric or other motors, motor-cars, omnibuses, vans, carriages, vehicles, locomotives, dynamos and apparatus, &c. The subscribers are :—R. G. Orr, E. F. Stranack, L. Fiedler, F. R. Graves, L. V. Oswald, L. H. Raw, V. C. G. Marden. Minimum cash subscription, £100. The number of directors is not to be less than two nor more than five; the first are R. G. Orr, E. F. Stranack, and L. Fiedler. Qualification, £100. Remuneration, 2 guineas each per board meeting attended (chairman, 3 guineas), and 5 per cent. of the net profits after 10 per cent. is paid on the ordinary shares. Registered office, 709 Salisbury House, E.C.

HAVANA TELEPHONE SECURITIES CO.—This company was registered on April 24th, with a capital of £1,000 in £1 shares, to acquire any bonds, debentures, securities, obligations, coupons, notes, scrip, shares, stock, or capital of the Havana Telephone Co. (incorporated in New Jersey, U.S.A.). The subscribers are :—W. Hicks, F. Birch, E. A. Lewis, F. J. White, G. L. Devisse, W. G. Dunstall, F. H. Nicholson. No initial public issue. The number of directors is not to be less than three nor more than nine; the subscribers are to appoint the first. Qualification, £200 debentures or £10 shares. Remuneration as fixed by the company.

F. HILLIER & CO.—This company was registered on April 16th, with a capital of £1,000 in £1 shares, to carry on the business of exhibition stand fitters, electric light installers, furniture and brass and copper letter dealers, decorators, builders, manufacturers of electrical plant, &c., and to adopt an agreement with F. Hillier. The subscribers are :—J. Robertson, H. Child, E. E. Ban, A. North, F. Hillier, L. Fayolle, F. A. Black. No initial public issue. Registered without articles of association. Registered office, 25 Brewer Street, Regent Street, W.

IMESON, FINCH & CO.—This company was registered on April 15th, with a capital of £10,000 in £1 shares, to acquire the business carried on at Stockton-on-Tees as "Imeson Brothers, Finch & Co.," to adopt an agreement with A. Imeson and A. H. Finch, and to carry on the business of electric, mechanical, and general engineers, machinists, smiths, founders, fitters, metal workers, manufacturers of roller controller fingers, roller contacts, automatic ears, trolley heads, lamps, samnite bronze, overhead electrical equipment and insulators, gear-wheels, and pinions for tramways and railways, &c. The subscribers are :—G. P. Lewis, J. H. Phillips, A. Imeson, A. H. Finch, Major H. Hart, N. White, C. H. Norris. Minimum cash subscription, £750. The number of directors is not to be less than two nor more than five; the first are G. P. Lewis, J. H. Phillips, A. Imeson, A. H. Finch, and Major H. Hart. A. Imeson and A. H. Finch are joint managers, with not less than £250 each per annum. Remuneration of directors, £50 each per annum, and 5 per cent. of the net profits available for distribution in any year when 10 per cent. is paid on the ordinary shares, Table "A" mainly applies. Directors' borrowing powers restricted to the amount of the nominal capital. Registered office, 5-6 Great Winchester Street, E.C.

PRIVATE TELEPHONE CO.—This company has been registered with a capital of £1,000 in £1 shares to adopt an agreement between M. Atkinson, M. C. Greenhill, and L. M. Porter to carry on business of electricians and manufacturers of and dealers in electrical apparatus, mechanical and electrical engineers. No initial public issue.

SAFETY LIGHT.—This company was registered on April 22nd, with a capital of £150,000 in £1 shares, to adopt a certain agreement (the parties to which are not named), to acquire and turn to account inventions, processes, patents, brevets d'invention, licenses, concessions, rights and privileges, and to carry on the business of electrical engineers, producers of electric light or power, gas makers, vendors, and suppliers, water supply engineers, founders, toolmakers, &c. The subscribers are :—A. Shanks, D. N. Ritchie, J. A. Tinling, H. M. Carter, A. C. M. Anderson, H. E. Smith, L. B. de Laitte, E. Walden-Vincent. No initial public issue. The number of directors is not to be less than five nor more than nine; the first are A. Shanks, D. N. Ritchie, J. A. Tinling, L. B. de Laitte, E. Walden-Vincent, and one other to be nominated by the de Laitte Gas Machine Co., Ltd. As soon as the Elwell-Smith Petrol Safety Gas Co., Ltd., shall have subscribed for £22 500 of an issue of £40.000 first mortgage debentures, the said D. N. Ritchie, E. Walden-Vincent, and J. A. Tinling shall have the right to nominate one other director. Qualification (except first directors), £250 shares. Remuneration (except managing director), £150 each per annum (chairman, £200), and 5 per cent. of the distributed net profits when 10 per cent. dividend is paid, to be increased to 10 per cent. when more than 10 per cent. dividend is paid.

SYLVERLYTE ELECTRIC LAMP CO.—This company was registered on April 24th, with a capital of £2,750 in £1 shares (1,500 preferred ordinary and 1,250 deferred ordinary), to acquire and turn to account any invention relating to the manufacture of electric and other lamps, and any lenses, reflectors, or other accessories used in connection therewith; in particular, to acquire the benefit of an invention referred to in an agreement with J. S. Burns, and to carry on the business of manufacturers of electric lamps, reflectors, lenses, and other articles, opticians, glass-blowers, &c. The subscribers are :—A. Hill, J. S. Burns, S. F. Rumball, A. H. Skan, F. E. Hodges, N. Richardson, H. A. Wilding. No initial public issue. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first. Qualification, 50 shares. Remuneration according to profits.

WARNER ENGINEERING CO.—This company has been registered with a capital of £2,000 in 20 founders' shares of £5 each, and 1,900 ordinary shares of £1 each, to acquire patent No. 15,059 of 1905 granted to J. S. Warner for improvements in railway and tramway trucks, together with the American, German, French, and other patents with regard to these trucks, and to acquire the business carried on by J. S. Warner as the Warner Engineering Co. No initial public issue. Registered address, 11 Dartmouth Street, Queen Anne's Gate, London, S.W.

OFFICIAL ANNOUNCEMENTS AND SMALL ADVERTISEMENTS.

Official Advertisements are charged at the rate of 1/- per line (column width).

Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of 1/- for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post.

Letters should be addressed to THE KILOWATT PUBLISHING CO., LTD., 203-6, Temple Chambers, London, E.C.

LECTURES.

NORTHAMPTON POLYTECHNIC INSTITUTE.
St. John Street, London, E.C.

WIRELESS TELEGRAPHY AND TELEPHONY.

A SPECIAL ADVANCED COURSE OF SIX LECTURES, followed by practical demonstrations, on Wireless Telegraphy and Telephony will be given on *Monday Evenings, at 7 p.m.*

Commencing MONDAY, 4th MAY, 1908.

Lecturer:
DR. J. ERSKINE MURRAY, M.I.E.E.

For further particulars of these classes, and details of all the work of the "Northampton," application should be made at the office, or in writing to

R. MULLINEUX WALMSLEY, D.Sc.,
Principal.

GREAT WESTERN RAILWAY.

Industrial Sites.

SITES suitable for the establishment of Factories and Works are available adjoining the Great Western Railway within easy access of the Principal Ports, Coal and Iron Fields, and Industrial Centres. Particulars of such sites and of the Company's arrangments for Siding Facilities, Conveyance Rate, etc., etc., may be obtained from the Chief Goods Manager, **Mr. T. H. RENDELL, Paddington Station, W.**

SUMMARY

THE new 6,000 kw. turbo-alternator which was put to work on Tuesday at the Stuart Street Lighting Station of the Manchester Corporation Electricity Department forms the largest generating set in this country. (Page 685.)

THE London Electric Supply Companies are making another effort to arrange for a co-operative electrical exhibit at the Franco-British Exhibition. With this end in view, the companies on their own initiative have taken space in the machinery gallery, upon which it is proposed to erect a pavilion. This will be divided into a number of sections showing various applications of electricity, including a furnished house, the fitting of which has been arranged by Messrs. Waring. An appeal is being made to the electrical industry to subscribe towards the expenses of wiring, the supply of current, &c., to the exhibit, the companies themselves providing sufficient funds to meet the expense of space and the pavilion which it is proposed to erect. (Page 685.)

LETTERS are published from several correspondents relating to the adoption of the term "wire lamp" instead of the more cumbrous definition "metallic filament lamp." It is pointed out by some that with one exception the filaments are not wire drawn, and the term "metal lamp" is put forward as a substitute. (Page 686.)

ARRANGEMENTS have been made for an electrical supply for the power and lighting needs of the Franco-British Exhibition aggregating about 6,000 kw. About half of this supply is taken in bulk from the special feeders of the Hammersmith Borough Council and the Notting Hill and Kensington Company, and the remainder is generated within the Exhibition. Three independent distributing services are laid down on the single-phase three-wire at 2 × 220 volts, three-phase four-wire at 220 volts and continuous-current three-wire at 2 × 250 volts. The whole electrical installation is of a substantial nature, and is said to have cost £30,000. (Page 687.)

PROFESSOR SILVANUS P. THOMPSON gave the first "Kelvin" lecture before a crowded meeting at the Institution of Electrical Engineers last Thursday. The lecture was devoted to an account of the life and work of Lord Kelvin. (Page 691.)

AT the Institution of Electrical Engineers on Thursday, Mr. H. F. PARSHALL presented a bronze bust of Benjamin Franklin on behalf of the American Institute of Electrical Engineers. He stated that it had been the original intention to present the bust on the occa-

Digitized by Google

sion when Lord Kelvin took the chair as President of the Institution of Electrical Engineers, but, alas, that was not to be. (Page 694.)

THE Marseilles Electrical Exhibition was opened on April 14th. (Page 694.)

THE Edison nickel-iron cell is used in the Bergmann electrically-propelled vehicles With the exception of the heaviest type of delivery waggon all the cars are provided with only one motor geared to the back axle through toothed gearing in the case of the lighter vehicles, and through chain gearing in the case of the heavy waggons. The control is effected by splitting the battery into two halves, and putting these halves in parallel or series. The series fields of the two-pole machine are also either in parallel or series. Some particulars of the cells, which are of particularly robust construction, are given. (Page 695.)

WE publish a detailed description of two unusually large cables—a telephone cable containing 800 pairs of wires, and a composite telegraph and telephone cable containing 64 screened telegraph wires and 49 pairs of telephone wires. Both are employed by the British Post Office. (Page 697.)

A NEW type of small transformer for use with low-voltage metallic filament lamps has been put on the market. A novel feature is the turn-down device which may be obtained embodied in the transformer case, which is very compact and can be suspended from the flexible between the switch and the lamp. (Page 698.)

A NEW method of controlling tramway points electrically without the necessity for an attendant has been introduced. (Page 699.)

A SPECIAL form of overhead contact rail and pantograph collector is used in the East River Tunnel, New York. (Page 700.)

ALTHOUGH the electric lighting arrangements at the Edinburgh Exhibition, opened on Friday, represent a capacity of some 575 kw., there is a large amount of gas lighting. An article gives a detailed account of the electrical circuits, and also some particulars of the gas lighting. (Page 701.)

THE Paper by Dr. W. E. SUMPNER and Mr. J. W. RECORD upon new alternating current instruments, read recently before the Institution of Electrical Engineers in London, has been further discussed in Birmingham, when several engineers expressed favourable opinions on the new instruments described. (Page 702.)

MR. T. P. WILMSHURST, Borough Electrical Engineer, Derby, has sent us some extremely interesting observations of the life of 100-volt Osram lamps used for street lighting. The best lamp had a life of 4,114 hours, and the average life of the 23 lamps, on which there is complete information, comes out at 1,570 hours. Some details of comparative costs, showing a great saving as compared with incandescent gas lighting, have been received from Mr. G. WILKINSON, Chief Electrical Engineer, Harrogate Corporation. (Page 703.)

UNDER ELECTROCHEMISTRY AND ELECTROMETALLURGY an article by A. Ahlin upon "Electrolytic Bleach Liquor," in which it is shown that particular precautions are necessary in order to ensure high yields and yields of constant composition. Some authorities prefer the presence of magnesium salts, because it is considered that they prevent reduction at the cathode by producing protective coatings of oxychloride; and when magnesium salts are not present in the raw product it is customary to add them. But Ahlin considers their presence to be a disadvantage. Tin can be smelted in the electric furnace apparently satisfactorily, although we do not know that it has been tried on an industrial scale. (Page 704.)

UNDER ELECTRICAL SCIENCE, in the British and American section, are an account of Lord RAYLEIGH'S installation as Chancellor of the University of Cambridge, a summary of Prof. LARMOR'S Royal Institution lecture on Lord Kelvin, and a note on an improved form of high resistance; in the Papers abstracted in the Continental section, F. NÈGRE deals with a resistance of porcelain insulators at high voltages; B. GLATZEL describes a new method of producing slightly damped oscillations; and PAUL ASTEROTH investigates the hysteresis of magnetic alloys. (Page 704.)

AMONG the specifications published by the Patent Office last Thursday was one by E. RUHMER, relating to a system of wireless telephony, in which a series of groups of undamped waves are sent out by the transmitter instead of, as in the previous system, a continuous train of waves of varying amplitude and frequency. A specification by the BRITISH THOMSON-HOUSTON Co. describes an improved method of welding metallic lamp filaments to leading-in wires; and another by the SIEMENS & HALSKE AKT.-GES. relates to the manufacture of tungsten filaments. An improved method of artificial cooling for railway motors is patented by C. O. MAILLOUX, and a commutator motor of the inverted repulsion type is described in a specification by the FELTEN & GUILLEAUME-LAHMEYERWERKE AKT.-GES. (Page 705.)

THE Belfast Corporation recommend that a through service of cars be maintained over the lines of the Cavehill and Whitewell Tramway Co., the company to receive the receipts at their end of the route and the Corporation the receipts at their end.—A list of certificated electric wiremen is being drawn up by the Birmingham Electricity Department.—Dealing with the question of renewal of tramway track, Mr. F. AYTON, the Electrical Engineer and Tramway Manager at Ipswich, estimates that the whole of the rails will require relaying in 1919, and that the cost will be £42,500. By 1919 only £10,408 of the original loan for track will have been paid off, thus leaving a sum of £32,092. Mr. Ayton's suggestion of levying a rate to meet this, owing to the improbability of the receipts being sufficient to cover the balance, has been vetoed by the Finance Committee.—In consequence of owners of property compelling the Middlesex County Council to acquire the whole when only a portion would be required for the purposes of the tramway undertaking, it has been found necessary to apply for additional borrowing powers to the extent of £100,000. (Pages 707–709.)

LOCAL Government Board inquiries have been held during the week in connection with electric lighting loans at Brighouse (£3,624), Burnley (£26,406), Colne (£4,170), and Taunton (£2,000). A Lancashire boiler and superheater are required by the Darlington Corporation; stores by the Metropolitan Asylums Board; cooling towers, tanks, &c., by the Salford Corporation; and switchgear, &c., by the Bristol Corporation. A scheme of extensions at the Dickinson Street and Stuart Street generating stations of the Manchester Corporation has been drawn up, involving an expenditure of £135,000. Messrs. Marple, Leach & Co. have secured the contract for the complete electrical equipment of the Tyne Ring Spinning Co., near Manchester. Messrs. Ferranti, Ltd., are supplying 55 transformers to the St. Petersburg Corporation, and a 1,000 kw. Siemens alternator, with a turbine by Messrs. Howden & Co., is being supplied to the Wimbledon Urban District Council. (Pages 709–710.)

THE accounts of the Great Northern Telegraph Co. show a decrease of about £13,200 for 1907 over those of 1906. A 20 per cent. dividend is declared, how-

Digitized by Google

ever. Commodore Suenson, the Chairman and Managing Director, has resigned on account of ill health, and the company has decided to substitute for the managing director, a Board of Managing. A balance of £18,116 is shown in the accounts of the National Electric Construction Co. for 1907, and after meeting various charges the sum of £9,047 is carried forward. The report of the South Metropolitan Electric Tramways & Lighting Co. for 1907 shows a surplus of £8,477, and after deducting depreciation, preference share dividend, &c., a balance of £437 is carried forward. The annual general meeting of the British Westinghouse Co. was held on Monday, when the chairman stated that the affairs of the company were now in a very much more satisfactory position. A feature of the year's operations were the economies which had been effected in the management, for with a pay roll of 2 per cent. less, an output having an additional value of 10 per cent. had been produced. (Pages 711–712.)

AT Bournemouth on Friday evening last, a tramcar belonging to the Corporation left the rails at a curve after descending a steep hill at a high speed. At the Board of Trade inquiry, opened by Major Pringle on Monday, and continued on Tuesday, evidence was given which showed that, although one magnetic brake shoe was broken before the accident, the other three were in good condition. The rear controller was found in the reverse position after the accident, and in this position it would have been impossible for the magnetic brakes to have acted. There is some doubt as to whether the wheels skidded or not. The inquiry is adjourned in order that the driver, who is slightly injured, may attend. (Page 713.)

THE annual general meeting of the Marconi Wireless Telegraph Co. was held on Thursday. Sir CHARLES EVAN-SMITH, the chairman of the company, who presided, said that the company had now accepted, under certain provisos, the principle of intercommunication, while the Post Office, on their side, acquiesced in and promised their favourable consideration and support to several very important matters. The company believed they would now receive the support of the Post Office, Colonial Office, the Admiralty, and the Foreign Office. With regard to the progress of their undertaking, they were now securing a profitable business all over the world, America, Canada, South America, France, Italy, Russia, Belgium, and China all having come to the company for apparatus and installations. Mr. MARCONI, who seconded the report, said that he had recently carried out some tests with short distance stations with the result that duplex working had been rendered possible. If this were applied to transatlantic stations it should double the rate of telegraphing. He was confident that with slight modifications of the apparatus, a speed of at least 30 words a minute could be obtained in ordinary working. (Page 715.)

AT the Municipal Exhibition, which was opened on Friday last at the Royal Agricultural Hall, Islington, there are very few exhibits of an electrical nature. At the Conference in connection with the Exhibition two papers will be read on Illumination. (Page 716.)

WE are very pleased to be able to announce in this issue that the scheme for a Co-operative Electrical exhibit at the Franco-British Exhibition, which a few weeks ago appeared to have fallen through, has been revived in a somewhat different form, and through the energies of a combination of the London Electric Supply Companies, the British electrical industry will be represented in one of the buildings of the exhibition. It would indeed have been a pity, considering how much has been talked of the wondrous display to be given by those interested in the use of gas and the excellent examples of French electrical engineering that will be seen, if the matter had been allowed to lapse. Some details of what is now proposed will be found in a circular from Mr. F. J. WALKER, Hon. Secretary of the Conference of Chief Officials of the London Electric Supply Companies, which was convened to take up the question. There will be a good deal of electrical interest in the power and lighting arrangements of the exhibition, and modern developments in generating sets will be well represented by a large steam turbo-generator, numerous gas-driven sets, and a Diesel engine, all of which will be actually in use. At this season there is a good deal of activity in the direction of exhibitions, and in this issue we are able to give a certain amount of information regarding the electrical particulars of the Scottish National Exhibition at Edinburgh, and the Marseilles Electrical Exhibition, as well as a long special article on the electrical arrangements at Shepherd's Bush. The much more extensive employment of gas than electric light at the Edinburgh Exhibition should not fail to be observed by the electrical engineer, and should be contrasted with the completeness of the electric lighting at the Franco-British Exhibition. It is true that great use is made at Edinburgh of electric lighting, but gas lighting is very prominent in the grounds and buildings, in spite of the obviously greater convenience and safety of electric lighting. It is unsafe to hazard an explanation for this, for the rules governing the allotment of exhibition contracts differ considerably from those followed in ordinary commercial cases, but the fact cannot be passed by without notice. Even more surprising is the neglect of the claims of the metallic filament lamp by both exhibition authorities. From our accounts of both exhibitions it will be noticed that at the Franco-British and the Edinburgh Exhibitions carbon filament lamps are to be employed principally for decorative lighting, although alternating current is available and pressures of 25 volts might easily have been provided by the use of transformers locally. The extra cost of installing these transformers would, we should think, have been amply covered by the saving in electrical energy, but the cost of the lamps would have been several times as much, and probably difficulty would have been experienced in obtaining delivery of the very large numbers required. It is still possible that when the fitting-up of the lamps for decorative purposes in Edinburgh is carried out, low-pressure metallic filament lamps will be employed; for the outlining of the buildings at Shepherd's Bush, however, the carbon lamp has been chosen. It is probable, however, that when the lighting of the stands is more complete we shall find that a large proportion of those exhibitors who are paying for their supply by meter will take full advantage of the great economy of the new lamps, although such incentive will be wanting in the case of the smaller stand-holders whose charges are based on a fixed amount per 16 or 8 c.p. lamp, as the lower initial cost of the lamp itself will be the predominating consideration.

ATTENTION must be directed to the excellent results of the life records of 100-volt Osram lamps which have been obtained in street lighting at Derby and elsewhere. It is truly remarkable that such results should

Digitized by Google

be obtained in these early days of the metallic filament lamp industry, and it speaks well for the future that lamps containing four separate filaments, each nearly as long as the single filament of a 100-volt carbon lamp and of about one twenty-fifth of the section should show such consistent and reliable results. The position of the 200-volt metallic filament lamp is made promising by these tests, for the average life of about 1,570 hours leaves a margin for considerable diminution. At Harrogate, too, excellent results have been obtained, and an even higher average life is indicated; and Mr. G. WILKINSON calls attention to a curious fact, that the life of the lamps seems longer when not enclosed in globes, owing, possibly, to some temperature effect. His figures of costs effectually prove that street lighting by Osram lamps is considerably cheaper than gas.

As we stated in our last issue, we trust that the term "wire lamp" will soon replace "metallic filament lamp" in general use. Some correspondents raise technical objections in letters printed in another column, but we think that it should be generally agreed that it is quite accurate enough for practical purposes to call the "filament" a wire, even when it is not wire-drawn. Before adopting the name definitely in our columns, however, we await some further expressions of opinion on the matter, for its use by a minority only would lead to occasional confusion. The term "metal lamp," which has been suggested as a substitute, seems to have some advantages.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, MAY 7TH.

Royal Society.

4 p.m. Meeting at Burlington House. Among the Papers down for reading are the following:—(1) "Helium and Radioactivity in Rare and Common Materials," by the Hon. R. J. Strutt, F.R.S. (2) "A Tantalum Wave Detector and its Application in Wireless Telegraphy and Telephony," by L. H. Walter, communicated by Prof. J. A. Ewing, F.R.S.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at the Society of Arts, John Street, Adelphi. Paper to be read:—"The Manufacture of Electrical Condensers," by G. F. Mansbridge.

Röntgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London, W. Agenda:—Paper by Dr. Horace Manders on "Continuous Oscillations of Electricity and Their Application." Mr. R. S. Wright will show and explain the new "Vita" interrupter for obtaining an increased output from an induction coil without a corresponding increase of primary current.

FRIDAY, MAY 8TH.

Physical Society.

8 p.m. Meeting at the Royal College of Science, South Kensington. Mr. C. G. Whitehead will read a Paper on "An Examination of the Formulæ for the Grading of Cables."

Association of Engineers-in-Charge.

8 p.m. Annual Meeting at the St. Bride's Foundation Institute, Bride Lane, Fleet Street, E.C.

TUESDAY, MAY 12TH.

Faraday Society.

8 p.m. Meeting at the Institution of Electrical Engineers, 92 Victoria Street, Westminster. Agenda:—(1) "The Industrial Uses of Ozone in Connection with Water Purification," by Dr. F. M. Perkin. (2) "Determination of Boiling Points of Very Small Quantities of Liquids," by L. O'Dowd and Dr. F. M. Perkin. (3) Dr. Veley, F.R.S., will exhibit an apparatus for measuring dielectric constants of non-conducting liquids.

Institution of Electrical Engineers: Glasgow Local Section.

8 p.m. Annual General Meeting. Messrs. Handcock and Dykes' Paper on "Electric Supply Prospects and Charges as Affected by Metallic Filament Lamps and Electric Heating" will also be discussed.

Incorporated Institution of Automobile Engineers.

8 p.m. Meeting at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, when the following Papers will be read:—(1) "The Effect of Motors on Roads," by D. Mackenzie (from the Motor Engineer's point of view) and W. J. Taylor (from the Road Engineer's point of view). (2) "Notes on Wheel Diameters," by Col. R. E. B. Crompton, C.B.

THURSDAY, MAY 14TH.

Iron and Steel Institute.

10.30 a.m. Annual Meeting at the Institution of Civil Engineers, 25 Great George Street, Westminster, London.

7 p.m. Annual Dinner in the Grand Hall of the Hotel Cecil.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at the Society of Arts, John Street, Adelphi, London. Paper to be read:—"Switchgear Control Apparatus and Relays for Alternating-Current Circuits," by Dr. C. C. Garrard.

FRIDAY, MAY 15TH.

Iron and Steel Institute.

10.30 a.m. Annual General Meeting at the Institution of Civil Engineers, 25 Great George Street, Westminster, London.

SATURDAY, MAY 16TH.

Birmingham and District Electric Club.

7 p.m. Meeting at the Colonnade Hotel, New Street, Birmingham. Paper to be read:—"Electrical Porcelain," by H. W. Brady.

Kent Collieries Electrical Plant.—In the Official Referee's Court on Wednesday, Mr. Muir Mackenzie had again before him the action brought by Messrs. Ernest Scott & Mountain, Ltd., against the Kent Collieries, to recover the balance of the contract price for electrical plant supplied, and further sums for wages paid and for repairs. Defendants pleaded that the plant was not in accordance with the contract, and counterclaimed for damages to the amount of £48,000. At the last hearing evidence was given for the plaintiffs by Mr. Hodgkin, assistant managing director of the company, and Mr. Mountain, director (see ELECTRICAL ENGINEERING, April 16th, page 601). Mr. J. J. Prest, a Durham colliery manager and mining engineer, who gave evidence on behalf of the plaintiffs, said that the machines supplied were quite in accordance with the specifications. Mr. Morley, who was left in charge of the work, remarked on the difficulty of working the pumps in the shaft, owing to the amount of suspended matter in the water. Several times the pump was choked up altogether, and in December, when he examined the pump, he found the spindle was reduced in diameter from 3¼ inches to 2⅝ inches, due to the action of the suspended matter. Other evidence was given to show that the generators supplied were of the required output, and that steam plant had not been properly looked after. Mr. Morley thought that the cause of the breakdown of the pump motor was the condensation of moisture after the machine was stopped. It had been running for some time, and was hot. After 3½ hours it was started up again, without any preliminary drying out of the coils. With regard to the delay, witness said that he was obliged to write to his own company for materials which he had expected to be supplied with. Mr. Bousfield opened the defence by saying that from the defendants' point of view the counterclaim was the most serious part of the case. The Kent Colliery Co. had raised some £100,000 in cash in order to take over the Dover Colliery, and continue the work. As a result of the failure of the motors and pumps, a large amount of the capital had been sacrificed. They had used the plant, though it was not capable of doing the work, without overheating, in order to save time. Counsel thought that the plaintiffs should have reckoned on the serious result of condensation in such enclosed motors. The motors, he said, had never had anything like their full load without overheating and breaking down. The plaintiffs had guaranteed a steam consumption of 28 lbs. per kilowatt hour, but the actual consumption had been 47 lbs. Plaintiffs, however, contended that they guaranteed the consumption to be 28 lbs. of steam per kilovolt-ampere, not per kilowatt. Mr. Bousfield, continuing, said that the first pump was not delivered until two months after the date fixed by contract, and he held that the defendants were entitled to compensation for this delay. The work of pump should have occupied only a fortnight, whereas it actually took five months. The defendants claimed damages for this delay also, which, they held, was entirely due to the incapacity of the plant supplied. The hearing was adjourned.

NEW 6,000 KW. TURBO-ALTERNATOR AT THE MANCHESTER CORPORATION ELECTRICITY WORKS

Inaugural Ceremony

ON Tuesday the Lord Mayor of Manchester (Mr. Edward Holt) performed the ceremony of starting up a new 6,000 kw. turbo-alternator at the Stuart Street works. We are obliged to postpone our detailed description of the set until our next issue, but it is interesting to note that it is not only the largest generator running in this country (or one of the largest, since the latest ones at Carville, Newcastle, have about equal output), but it is also, we believe, the first large turbo-alternator that Messrs. Siemens Bros.' Dynamo Works have supplied in England, and the largest steam turbine that Messrs. Willans & Robinson have yet built for any electricity works. The machine will supply three-phase current at 6,500 volts, between phases and 50 cycles frequency, and runs at a speed of 1,000 revs. per minute.

Although not precisely of the Continental "chimney" type, the alternator is cooled by forced ventilation, supplied by a Sirrocco fan in a small building outside the generating station. This air circulates through the machine, and then passes out again by a separate air duct from the base of the station.

Beneath the turbine is a Richardson-Westgarth "contraflo" surface condenser with electrically-driven pumps. At present the existing boiler plant and the existing cooling towers are employed, but extensions will shortly be made.

The Lord Mayor of Manchester presided at a dinner held in honour of the occasion in the evening. In responding to the toast of the Lord Mayor and Corporation, proposed by Mr. Alexander Siemens, he said that he considered that trading committees of municipalities should make at least 5 per cent. profit in aid of rates, after proper amounts had been set aside for depreciation and reserve fund, in addition to the sinking fund. Councillor Royse proposed "The Trade and Commerce of Manchester," and Mr. Francis Ashworth, President of the Manchester Chamber of Commerce, replied.

Dr. E. Hopkinson, in giving the toast of the Electricity Department, called attention to the progress that had been made since the first station was built in Dickinson Street fifteen years ago, under the advice of his brother, the late Dr. John Hopkinson. The output was half a million units per annum then; for the year 1907–8, it was 63 million units from the present Manchester electricity works. He called attention to the fact that the five-wire distributing system originally laid in the centre of the city is still in use. Councillor Howarth, Chairman of the Electricity Committee, in his reply, dealt first with the Lord Mayor's remarks as to profits. He said that a duty as important as relieving rates was the supply of power at low but remunerative rates to encourage the Manchester industries, and also to lessen the smoke emitted by the manufacturing works. There were, he pointed out, 1,000-h.p. plants near at hand giving out as much smoke as the Stuart Street station with its 30,000 h.p. The output of 63 million units for the year closed on March 31st last, was an increase of 16 million units over the previous year, and, in spite of reduction in price charged to consumers and to the tramway department and an increase in the price of coal, there had been a large surplus over the estimates.

Councillor Kay, Deputy Chairman of the Electricity Committee, proposed "The Visitors," and Mr. Bythell, Managing Director of the Manchester Ship Canal, responded. The last toast was that of "The Contractors," given by Alderman Jennison, Chairman of the Stuart Street Sub-Committee, who expressed his confidence in the firms employed to carry out the contracts, and referred to the fact that the accepted tender had not been the lowest. [The lowest tender was by the Westinghouse Co., and was not accepted, but we believe the difference in price was not great.] Mr. Peache, of Messrs. Willans & Robinson, in his reply, referred to the assistance that had been given him by Mr. Pearce, the City Electrical Engineer, in carrying out the work.

THE FRANCO-BRITISH EXHIBITION

Co-operative Electrical Exhibit

IN connection with the announcement made in our issue for April 16th, page 579, that the endeavour made by Dr. R. T. Glazebrook and Mr. C. S. Northcote to secure support for a co-operative electrical exhibit at the Franco-British Exhibition had failed, we are pleased to see that the idea is not to be entirely abandoned. The London electric supply companies from the commencement have strongly urged the need for such an exhibit, and the following letter, which we have received from Mr. F. J. Walker, secretary of the St. James's and Pall Mall Electric Light Co., and hon. secretary of the Conference of Chief Officials of the London Electric Supply Companies, indicates that they are not disposed to abandon the project. The history of the previous effort was given in our issues for April 2nd and 16th. Mr. Walker's letter, which is being sent around to the trade, is as follows:—

You are doubtless aware that the steps which were taken to organise a collective electrical display at this Exhibition were recently abandoned through lack of sufficient support. The Electric Supply Companies of London are strongly of opinion that, having regard to the magnitude of the Exhibition, the importance of which has not as yet been sufficiently realised, it would be detrimental to the interests of the industry if further efforts are not made to remove the necessity for this decision, and they have therefore resolved to make this appeal to the trade to secure their co-operation in promoting a collective exhibit worthy of the occasion.

With this end in view, and because of the shortness of time at their disposal, my Conference have taken upon themselves the responsibility of securing a suitable space in the Machinery Gallery, and have arranged with Messrs. Waring for the erection thereon of a handsome pavilion. Sufficient funds have been guaranteed by the Supply Companies to cover the cost of the space and pavilion, and the general superintendence of the exhibit will be undertaken free of charge by my Conference; but there remains the expense of wiring, current, and attendance still to be provided for, which may be estimated not to exceed £600. If, as is hoped, not less than thirty firms respond to this invitation, the average inclusive contribution per exhibitor would not be more than £20, and as there is no obligation on exhibitors to provide attendance (though they are, of course, at liberty to do so if they think proper), it will be seen that the cost of participation is extremely moderate. It is proposed that half this contribution should be paid before the opening of the exhibit, and the balance, or such amount of it as may be required, at a later date.

The pavilion will be divided up into six sections as follows:—(1) A suite of furnished rooms, comprising hall, dining-room, drawing-room, bedroom, nursery, and kitchen designed for the display of domestic lighting, heating, cooking, and ventilation. (2) Small machinery worked by motors. (3) Medical apparatus, including baths, high-frequency and X-ray appliances. (4) and (5) General exhibits. (6) Reception room and information bureau, which will be available for a few selected exhibits.

I am directed by the Conference of Officials to appeal to you to contribute to the success of this exhibit by signifying your intention of participating, and informing me what class of goods you propose to show and the approximate amount of space required. I shall be also greatly obliged if you will attend a meeting at this office on Wednesday next, the 6th inst., at 4 p.m., when the subject can be more fully discussed. I would draw your attention to one of the regulations of the exhibition that all goods exhibited must be of British production or manufacture.

CORRESPONDENCE

"WIRE LAMPS."

To the Editor of Electrical Engineering.

Sir,—On page 647 of your issue of the 30th ult., I note in your letter on "Metallic Filament Lamps" a reference to Mr. Mordey's suggestion that incandescent lamps with filaments composed of metal or metal alloy should be called "Wire Lamps." It seems to me that, although this name is more convenient than the usually accepted "Metallic Filament," it is somewhat of a misnomer. When one talks of a "wire" one has in mind a metal rod which has been drawn through a die. Now, most of the metallic filament lamps have filaments composed of more than one metal, and in some cases are certainly not entirely metallic; for instance, the "Osram" lamps at the present date contain a certain proportion of carbon in their filaments, though I am aware that this is an incident in manufacture and is not really intended. However, the case is as I state; in fact, it seems to me that the only lamp which can be called a "Wire" lamp without terminological inexactitude is the "Tantalum" lamp.

Yours faithfully,
E. C. L.

[In connection with this question, we have endeavoured to ascertain the views of some of the leading makers of these lamps, and give some of the most interesting of the letters which we have received so far below.—Ed. *E.E.*]

To the Editor of Electrical Engineering.

Sir,—We are in receipt of your letter of the 2nd inst., *re* suggestion to use the name "wire lamp" instead of "metallic filament lamp" as applied to this class of lighting. The term is certainly convenient, but we cannot say that it is appropriate. We would suggest as a simplified term the name "metal lamp," which we think would meet the views of everyone concerned.

Yours faithfully,
M. Grainger.
(Sunbeam Lamp Co., Ltd.)
Gateshead, May 4th, 1908.

To the Editor of Electrical Engineering.

Sir,—I am in receipt of your favour of the 2nd inst., and in reply beg to say that, to my mind, Mr. Mordey's suggestion that the term "wire lamp" be used in place of "metallic filament lamp" deserves commendation for the sake of simplicity. I fear, however, that to the "man-in-the-street" it would convey a wrong impression, for he would argue somewhat on these lines:—Why should I pay such a high price for these lamps when the filament is only made of *wire*? Even in the early days of electric incandescent lamps the layman's expression for the carbon filament was "the black wire." Viewed from a purely commercial aspect—which, after all, is a point of view not to be lost sight of by any manufacturer—I have great doubts whether merely the description "wire lamp" would be conducive in making the new current-saving device more popular. The tendency of the manufacturer is to coin a trade name for his product, and he tries to make it known by such. The more retentive that name is, the more frequent will be the inquiries for the article to which it applies. The old saying, "Give a dog a bad name," &c., may be paraphrased, "Give a new article a good name, and it will require no pushing."

Faithfully yours,
H. Oppenheimer.
(International Electric Co.)
55 Redcross Street, E.C., May 5th.

To the Editor of Electrical Engineering.

Sir,—Replying to your esteemed letter of the 1st inst, addressed to Messrs. Philips & Co., we would say we do not fall in with Mr. Mordey's suggestion to use the term "wire lamp" instead of "metallic filament lamp," seeing this is not a clear definition of the lamp in question.

Yours respectfully,
Philips' Metallic-Glowlampworks, Ltd.
Eindhoven (Holland), May 4th.

To the Editor of Electrical Engineering.

Sir,—We are in receipt of your letter of the 1st inst., and note that Mr. Mordey suggested the use of the term, "wire lamp" instead of "metallic filament lamp." We quite agree with you that the latter name is too long; at the same time, we do not consider "wire lamp" a proper term either. We think "metal lamp" would be much more appropriate, for the simple reason that, firstly, it is just as short as "wire lamp," and, secondly, as a number of metallic filament lamps are not made of wire. We have used the term "metallic filament lamp" for a considerable time, and our customers are quite used to it.

Yours faithfully,
J. Stottner.
(The Electrical Co., Ltd.)
Charing Cross Road, May 5th, 1908.

To the Editor of Electrical Engineering.

Sir,—We are in receipt of your letter of May 2nd, with regard to the suggested use of the term "wire lamp" for metallic filament lamps. As far as we are concerned, the matter does not appear to us to be of very great importance, but at present we are not inclined to agree to the term of "wire lamp," as most of the metallic filament lamps on the market are not made of wire. Perhaps some of your correspondents will be able to suggest another term, which would be more in keeping with the actual material used in the filament.

Yours faithfully,
C. Wilson.
(Robertson Electric Lamps, Ltd.)
Hammersmith, May 5th, 1908.

To the Editor of Electrical Engineering.

Sir,—Replying to your letter, I think that the term "wire lamp" is certainly terse, but it does not describe it sufficiently well. The word "wire" certainly suggests something far thicker than the filament of an "Osram" or "tantalum" lamp. The public has already begun to learn the name of metallic filament lamp in conjunction with the names "Osram" and "tantalum"; why complicate matters further by changing the name again?

Yours faithfully,
A. G. Beaver, Manager.
(Sun Electrical Co., Ltd.)
Charing Cross Road, May 5th, 1908.

International Conference on Electrical Units and Standards.—The President of the Board of Trade has appointed a committee, consisting of Mr. G. R. Askwith, K.C., Sir John Gavey, K.C.B., Dr. R. T. Glazebrook, F.R.S., Major P. A. MacMahon, F.R.S., Major W. A. J. O'Meara, R.E., C.M.G., and Mr. A. P. Trotter, to prepare a programme for the consideration of the Delegates to the International Conference on Electrical Units and Standards, to be held in London in the ensuing autumn, and to make arrangements for the reception and assembly of the Delegates attending the Conference. Mr. M. J. Collings, of the Board of Trade, will act as secretary to the committee.

THE ELECTRICAL ARRANGEMENTS AT THE FRANCO-BRITISH EXHIBITION

THE increasing part which electricity has played in various ways in large exhibitions during the last few years is very noticeable, and it is not to be wondered at that at so large a display as the Franco-British Exhibition, which opens next week in London, the arrangements for the supply of electricity for power and lighting form an undertaking of very considerable magnitude. In considering the special facilities for access to the site near Shepherd's Bush, one cannot help also noticing the prominent part played by electric traction. Special stations have been constructed on two electric railways, and electric tramways, forming part of two different systems, pass the doors. The extension of the Central London Railway, which will be dealt with more fully next week, includes a new station close to the Wood Lane entrance of the exhibition. Close to this, on the other side of the road and practically within the exhibition area, is the new station on the electrified Hammersmith and City Railway, which forms an intermediate station on that line between Shepherd's Bush and Latimer Road. The line is here carried on a viaduct of brick arches, and the station has been made by the addition of more or less temporary wooden platforms with the necessary stairs, &c., on each side of the viaduct. The London United Tramway terminus is opposite the so-called main entrance to the exhibition in Uxbridge Road, which is connected to the exhibition proper by a spacious overhead covered way some 70 ft. wide and 900 yards in length. This passage, which is not shown in the plan, is carried partly over the Central London Railway extension and terminates in a bridge over Wood Lane at the Wood Lane entrance. The other electric tramway connection is that of the new Hammersmith-Harlesden London County Council line, which crosses Uxbridge Road and passes up Wood Lane. This line is now in an advanced stage of construction, and is interesting as being the first L.C.C. line on the overhead trolley system. Electrical interest will, of course, centre around a certain proportion of the exhibits, particularly in the French section, and there is every reason to hope that the British electrical industry will be represented to some extent, owing to the revival of the scheme for a co-operative electrical exhibit, to which we have referred on several occasions. A consideration of the exhibits must be deferred until after the opening of the exhibition, but it is the purpose of this article to deal more particularly with the arrangements for the supply of electricity for lighting and power which, at the time of writing, are in a more advanced state than much of the work of other departments.

Some idea of the magnitude of the undertaking may be gathered from the facts that the area of the exhibition site is 140 acres, not including the passage-way to Uxbridge Road, which accounts for another 4 acres; over 2,000 arc lamps are used in what may be called the public lighting as distinct from the lighting of the stands, and the whole electrical installation is said to have cost about £30,000, of which the cables alone account for about £20,000. The maximum load taken from the bulk supply from external sources, to which reference is made below, is 3,000 kw., and generating plant, aggregating about the same capacity, is provided within the exhibition. It should be emphasised that the electric supply arrangements in no way partake of the nature of a temporary installation, but the whole of the work is of as substantial and permanent a character as the public supply of a town. Although we are told that gas is to make a wonderful show of its capabilities in the hands of a group of exhibitors, it is electric light and electric light alone that the authorities have relied on for the general and decorative lighting of the exhibition itself.

The bulk supply already referred to is taken under a contract with the Hammersmith Borough Council, in whose area of supply the whole of the exhibition lies. Only about one-half of the supply, however, comes from the Council's station in Fulham Palace Road. The remainder is provided by the Notting Hill and Kensington Electric Supply Co. from their station on the opposite side of Wood Lane, this company acting, so to speak, as sub-contractors to the Hammersmith Borough Council. The terms of the agreement

PLAN OF FRANCO-BRITISH EXHIBITION.

with the exhibition authorities provide for a charge of 1d. per unit from sunrise to sunset, and 2d. per unit from sunset to sunrise, with a minimum payment for the period from May 1st to October 31st of £10,000. The Hammersmith Council guarantee a consumption from the Notting Hill and Kensington Co.'s station of one million units, and will pay for this bulk supply at the rate of 0·8d. per unit, reduced to 0·75d. per unit for quantities over a million units.

The supply from the Hammersmith station is single-phase at 2,200 volts 50 cycles, and that from Wood Lane is three-phase at 5,000 volts 45 cycles. Special feeders have been laid in triplicate from each of the two stations, and these enter the exhibition grounds at the sub-stations, shown on the plan, under the railway arches close to the Wood Lane entrance. The single-phase and three-phase sub-stations are quite dis-

Digitized by Google

tinct, although of similar design and situated side by side.

The single-phase sub-station contains three 200-kw. single-phase Berry type air-cooled transformers, supplied by the British Electric Transformer Co., of Hayes, which step down to 2 × 220 volts, with tappings for a neutral wire for the three-wire single-phase distribution system, with the necessary switch-gear. These transformers and the switch-gear on the high-tension side are the property of the Hammersmith Borough Council, but the low-tension boards and wiring belong, of course, to the exhibition. The H.T. board has incoming feeder and transformer panels, and is equipped with Messrs. Cowan's oil circuit breakers, fitted with Mr. L. Andrews' patent discriminating release devices. All the H.T. apparatus is in substantial brick chambers, closed by gates of wire-netting, and the 'bus bars run horizontally along the top between slate partitions. The low-tension board is of simple, straightforward arrangement. The 'bus-bars are carried in front of the board and are sectionalised into three divisions, which can be isolated as desired by withdrawing the horizontally placed switch-fuses with which they are normally connected. Above the bars are the feeder switches and fuses, and at the bottom of the panels are the meters. Owing to the method of charging, a special double tariff meter, supplied by Messrs. Siemens Brothers' Dynamo Works, Ltd., is used in each circuit in conjunction with automatic time switches. The low-tension switchboards were supplied by the Universal Electrical Manufacturing Co., of Queen Street, Battersea. The neutral point of the three-wire system from this board is earthed in the sub-station. The three-phase sub-station equipment is precisely similar, except that the transformers, which are also of the Berry type, are three phase. The secondaries are star connected, and the distribution is four-wire with the neutral earthed in the sub-station. The number and capacity of the transformers are the same, and a similar subdivision of the 'bus-bars is employed. At the time of our visit an extra transformer was in use, connected temporarily to a main leading to another sub-station, to which reference will be made hereafter.

From these sub-stations a series of low-tension 220-volt exhibition feeders are run, from which distributors are teed off to points in the various buildings. Among these feeders, serving in the various buildings in the part of the exhibition south of the central gardens, are one which runs in a straight line along the east side of the Indian Court and on through the next court beyond and another further west. The whole of these feeders consist of lead-covered cable—three-core in the case of the single-phase three-wire feeders and four-core in the case of the three-phase feeders—laid underground in Sykes' patent conduit and provided with a complete system of drawing-in boxes. Brick pits are used at every joint-box and disconnecting-box. A special feature of the lay-out of these feeders is the arrangement of these disconnecting boxes, which are provided wherever a connection is taken into a building, so that by the removal of links any distributing section can be isolated. All the cables were supplied by the Western Electric Co., and were laid by the Reeds Electrical Co., of Southwark. The feeders from the single-phase sub-station range from 0·15 to 0·35 sq. in., and the three-phase feeders vary in size from 0·1 to 0·23 sq. in.

The single- and three-phase feeders, although quite independent, are run in all cases in the same group of ducts, and follow the same route, connections being taken off at the same places, so that at all points served by these sub-stations a duplicate supply is available. At the feeding points, therefore, large double brick chambers are provided, containing the single- and three-phase disconnecting boxes side by side. From these boxes leads are taken in porcelain conduit underground to the actual distributing points within the buildings. The three-phase and single-phase distributing points are, however, kept separate. At each of these points the switch-gear provided is usually as follows, with certain modifications in special instances. The cables first are branched into two, and two separate main switches are provided, one for the arc lighting circuits and one for the exhibitor's circuit. These switches are of a substantial, enclosed design of Messrs. Berry, Skinner & Co., combined with enclosed fuses. Above these switches are one row of switches for the separate arc light circuits. These are of the Cantie quick make and break type, each enclosed in a separate cast-iron case. Each switch has its double-pole fuse in an independent cast-iron case with glass front immediately above it. These fuses are of Messrs. Moy's tubular "no-ark" pattern. At the top of the board, as a general rule, are the line resistances for the arc lamps. The exhibition circuits running around the part of the building in question are taken direct from the other main switch already mentioned without further sub-division, and the circuit for each stand is teed off from these mains. From these circuits all the lighting of the stands is supplied, and small alternating motors, either single- or three-phase, up to 2 h.p.

The wiring in the buildings is all contained in screwed iron gas barrel, with the exception of those parts of the arc circuits up in the roofs, where open wiring of covered wire on bobbin insulators is employed, but no bare wire is used in any part of the exhibition.

The arc lamps are run four in series, and the circuits are arranged so that alternate lamps are on the single- and three-phase services, so that a failure of supply from either source will only extinguish half the lights. Three makes of arc lamp are employed in the exhibition. The "Sunshine" flame lamp by the Electrical Co., alternating flame lamp supplied by the Santoni Arc Lamp & Engineering Co., and the Maxim Electrical Co.'s enclosed lamp. There are also a few continuous-current Santoni lamps.

In addition to the arc and stand lighting, the alternating-current mains will supply from separate distributing points most of the decorative lighting in the part of the exhibition which they serve. This decorative lighting will form an important feature of the exhibition. Practically everyone of the elaborate white buildings is outlined externally by rows of incandescent lamps, varying in number from 2,000 in the smaller buildings to as many as 10,000 in the case of the largest structures. The lamps used are carbon filament 5 c.p. with Edison screw terminals, and the holders are wired in parallel on what is known as "Fairyland" strip. The lighting of the open-air spaces round each building is supplied in an exactly similar way, and many of the distributing boards, as described already, are fixed outside the buildings. In the case of the smaller kiosks, &c., a short length of inch gas barrel is usually run underground from the nearest feeding-point.

Thus far we have only considered the supply to the alternating-current circuits in the southern part of the exhibition, although what has been said regarding the low-tension wiring applies to a great extent elsewhere. The greater part of the rest of the supply, including the whole of the continuous-current light and power circuits, is fed from another sub-station adjoining the Machinery Hall, and the steam- and gas-driven generating sets in the hall itself. For the supply to this sub-station, a set of both single- and three-phase high-tension feeders, at 2,200 and 5,000 volts respectively, are run from the main intake point at the Wood Lane sub-station, following the route marked on the plan, and laid in the same manner as the L.T. feeders. The sub-station itself is divided into two rooms; one of

Digitized by Google

these contains a 150-kw. motor generator, manufactured by the General Electric Co., consisting of a standard induction motor of the ordinary slip-ring type, driving an interpole continuous-current 500-volt generator. The induction motor is run direct off the 5,000-volt three-phase circuit without the intervention of transformers. The starter is of the liquid type, and is placed close to the motor. High-tension switchgear of a similar nature to that in the Wood Lane substations is provided. The continuous-current circuit is intended partly for power at 500 volts and partly for lighting at 250 volts, and is, therefore, arranged as a three-wire system. For this purpose a small balancer set, placed in the same room as the G.E.C. motor generator, will be used. The adjoining room in the substation contains two Bruce Peebles-La Cour cascade motor converters, each of 400 kw. capacity, also converting to 500 volts continuous current. It is unnecessary to describe in detail the switch-gear by which any or all of the three converting set can be connected up to the 500- and 250-volt three-wire 'bus-bars from which the continuous-current distributing feeders are taken. The arrangement follows the same general lines as adopted in the alternating-current sub-station. The same sub-station will also give a single-phase alternating 220-volt supply to the neighbouring part of the exhibition from a group of 200-kw. Berry transformers, arranged in a similar way to those in the Wood Lane sub-station. At the time of our visit, however, the arrangements for this were not quite completed, and a 220-volt alternating supply was being taken temporarily over the high-tension mains from the extra transformer, already alluded to, in the Wood Lane sub-station.

The generating plant in the Machinery Hall, to which reference has already been made, will be connected up to the low-tension continuous-current switch-gear in the sub-station, and will form an alternative and additional supply to that given through the converting plant. Current will thus be supplied for the general purposes of the exhibition from two generating sets actually forming part of the exhibits in the Machinery Hall. One of these is a 1,000 h.p. Westinghouse gas engine of the three-crank vertical tandem pattern, direct coupled to a 750-kw. 500-volt continuous-current generator, and supplied with gas from a Mond gas plant exhibited by the Power Gas Corporation, and situated in a separate house close to the end of the Machinery Hall. The other set is a Parsons' turbo-generator set, rated at 1,800 kw. at 500 volts continuous-current, but capable, we understand, of 25 per cent. overload for a considerable period. This set is supplied with steam from a boiler-house near by containing three Babcock & Wilcox double-drum water-tube boilers, each of 10,000-lb. evaporation capacity per hour, and fitted with internal superheaters and automatic chain grates of the firm's latest type. The turbine will exhaust into a Körting ejector condenser, also in a separate building, adjoining the Machinery Hall. These two sets when ready will be connected up to a special switchboard, supplied by Messrs. Crompton & Co., interconnected to the sub-station switchboard in such a way that either the converter or generating plant, or both, can be used on the continuous-current power and lighting load. It is the general intention to take the supply during the day load from the sub-station, and run up the generating plant in the evening.

A number of feeders radiate from the continuous-current boards in the sub-station, some 500-volt only for power purposes and some three-wire feeders from which lighting at 250 volts can be supplied. Amongst these is a special feeder taken right across to the Stadium which is lighted by about 900 flame arc lamps. Another important feeder serving a large part of the northern section of the exhibition is carried round the outer of the two semi-circular avenues known as the Grand Avenue of the Colonies. A special power feeder is run to the "Flip-flap," a remarkable piece of "amusement engineering," near the centre of the exhibition. This machine is driven by a 125-h.p. continuous-current motor. A 250-volt feeder is also run in a northerly direction to the bridge over the lake in the Indian Court, where a charging board is to be provided for the electric launches that will ply on this lake and round the Venetian Canal. Another similar charging station will be established under the Imperial Pavilion. Among other applications of electric power fed from the continuous-current system will be two 40 h.p. motors driving centrifugal pumps for the water supplying the lake in the Indian Court. Most of the amusement devices, including the Canadian Scenic Railway, will also be electrically driven. It should also be said here that the whole of the illuminations in the Court of Honour are to be supplied by continuous current.

In addition to the arrangements made above by the exhibition for power and lighting, a certain number of exhibitors will have their own generating plants. The largest case of an independent plant is that of the buildings devoted to the exhibits of Canada and Australia, which will be supplied from a generating plant consisting of two 100-kw. 230-volt continuous-current dynamos, driven by three-cylinder vertical Westinghouse gas engines. The power and lighting for the *Daily Mail* kiosk, where an edition of that paper will be printed daily, will be derived from a set consisting of a Diesel engine driving a dynamo, manufactured by the Electric Construction Co., capable of an output of 225 amperes at 410 volts, and running at 194 revolutions per minute.

The following are extracts from the regulations for electric power and lighting of the stands, which will be of interest, as showing the conditions under which the supply is given to exhibitors and the care which is being taken to ensure sound work.

The wiring of the exhibitor's space must be carried out by the exhibitor at his own expense, and subject to the rules of the London County Council, London Fire Brigade, local and other authorities, as well as of the Engineer to the Exhibition. The current available will be for motive power in the Machinery Hall 500 volts continuous current; for lighting 220 volts single-phase and three-phase alternating current, 50 periods per second, except in buildings numbered above 50, and those situated in the northern portion of the Exhibition grounds, in which 250 volts continuous current only will be available. Each exhibitor shall supply and erect securely on his stand a hardwood board, having mounted thereon two main single-pole fuses in iron boxes, and a linked double-pole main switch enclosed in a hard wood or metal case; and in addition to this, where the number of incandescent lamps on the stand exceeds 15 lamps (5, 8, or 16 c.p.), a distribution board with a double-pole main fuse way for each circuit of 15 lamps. If the total number of lamps on a stand does not exceed 15, two single-pole encasing type porcelain cut-outs may be used, but the double-pole main switch shall be as specified above. Where conductors enter the back of distribution fuse or switchboards, which are mounted on woodwork, a sheet of asbestos, uralite, or other similar fire-proof material shall be placed behind the conductors. Cut-outs shall be of the high-pressure cylinder type, with tin fuse wire, having a margin of not more than 50 per cent. capacity. All switches must be of quick action, ample dimensions and break, and without intermediate position between "on" and "off." They must be placed out of reach of the public, and must not be beneath counter or in show-cases, but preferably be mounted and protected as distribution boards. Branch switches shall be of the tumbler type high-pressure pattern adapted to carry five amperes.

No bare conductors will be allowed. All conductors shall be of tinned copper, and shall be so proportioned to the work that the current density shall not exceed a ratio of 1,000 amperes to the square inch. All conductors, except flexible cords, shall be insulated with pure and vulcanised rubber, taped, braided, and compounded, and have an insulation resistance of not less than 1,000 megohms per mile. Flexible cord shall be insulated with pure or vulcanised rubber, and covered with stout silk, cotton, or other approved braiding. Its use must be restricted to pendants and portable appliances approved by the Engineer. Wires and cables shall be adequately and firmly fixed, and in all cases where wires are within reach of the public they must

Digitized by Google

be enclosed in wood casing or other approved covering. All joints must be soldered, and covered with pure rubber and proof tape. On circuits to carry more than 5 amperes clamped joints must be used. Unencased conductors must be out of reach of the public, securely supported on insulators, and tappings to lamp holders must be made by insulated conductors other than flexible cord, with properly taped joints. Unencased conductors must not be in contact with bunting, gauze, cloth, or other covering material.

Fairyland strips are allowed, but unless the holders are fitted with metal backs must be securely mounted on uralite or similar board or insulators out of reach of the public. No "E.L.B." flexible strip or boards will be allowed, unless in iron cases with glass fronts. Wiring at the back of wood sign boards must be encased. Wood casings with batten holders will be allowed. No imitation candles, shades, or other accessories made in celluloid will be allowed on fittings connected to the circuit, to accumulator batteries, or other source of supply.

If metal tubing be used, both lead and return wires must be in the same tube, and the tubes must be earthed unless exemption be granted by the Exhibition Executive. No socket-connected tubes will be allowed: all tubes must be screw connected, and electrically and mechanically continuous, and must not contain an open seam.

Where externally lighted signs are above 10 ft. from the floor or in positions inaccessible to the public, they may be wired in circuits of not more than 30 lamps of 5 or 8 c.p. Signs lower than 10 ft. will be treated as part of a stand, and must not have more than 15 lamps (5, 8, 16 c.p.) on a circuit. No sign must be fixed direct on woodwork, or within 12 in. horizontally or vertically of wood or cloth work, unless effectively protected by asbestos, uralite, or similar material. Internally lighted signs must be of fireproof construction, and each contain not more than 5 or 8 c.p. lamps; they must be open at the top, and have a number of 1-in. holes in the bottom or sides to permit of thorough ventilation. These lights must not be lighted from the inside without the special written consent of the above-mentioned authorities. No arc lamps will be allowed unless the written consent of the Exhibition Executive has previously been obtained.

Motors exceeding ¼ h.p. must be of the enclosed or enclosed ventilated type, and must be mounted on sheet-iron trays to catch oil. Ventilated openings in motors must be covered with metallic gauze if required by the Exhibition Executive. Such motors must be controlled through d.p. cut-outs, linked switches and fire-proof starting resistance, with "no-current" automatic release. Regulating switches must have the resistance enclosed in fire-proof cases. All switches with projecting handles must be placed in protecting cases, so that the levers cannot be accidentally moved from the "starting" to the "running" position when the circuit is dead. Machinery shall not be driven by electric motors unless the arrangement be approved by the Executive of the Exhibition, and shall conform to the London County Council requirements. If the "starting" current of any motor be excessive in the opinion of the Executive of the Exhibition, it may be necessary to arrange certain times for starting up; and the motor may have to be kept running between certain times, or be run only during certain times as may be arranged.

Neither live transformers nor charged accumulators will be allowed unless special permission be granted by the Exhibition Executive. Where stands are covered in with boarding, the roofing must be of solid construction, and the material be fire-resisting; where fibrous material is used for this purpose, it must be "treated" so as to be fire-resisting in accordance with the rules of the County Council.

The Exhibition Executive reserve the right of supplying and fixing at the expense of the exhibitor a meter for the purpose of registering current which may be consumed by the exhibitor. Should the Exhibition Executive decide in the case of any exhibitor to require him (the exhibitor) to supply and fix the meter, the exhibitor shall do so at his own cost, and the meter shall be of such make as may be approved of by the Engineer of the Exhibition. The reading of the meter so fixed on the exhibitor's stand shall be deemed to show the amount of current consumed, and payment shall be made by the exhibitor to the Exhibition Executive in accordance therewith. Should any meter cease to register, or register inaccurately, the Engineer of the Exhibition shall decide the amount which is payable by the exhibitor.

The Exhibition Executive will also connect the exhibitor's stand with the main circuits in each building, the expenses in connection with which will be charged to the exhibitor, and will be based upon the time occupied and the material used in making the connection; the certificate of the Engineer of the Exhibition shall be accepted by the exhibitor as final evidence of such expenditure.

Tariff of Charges.—For power purposes, 2½d. per B.T. unit. For lighting, 3d. per B.T. unit. Current during the period of the Exhibition, from dusk until close, for a 16 c.p. lamp a payment of 20s. per lamp. For a 8 c.p. lamp, 15s. per lamp.

In conclusion, it may be said that even if electrical engineering be not as well represented among the exhibits as some other branches of industry, the complete way in which the electrical arrangements of the exhibition have been carried out forms an object-lesson in itself. We wish to express our thanks for information given and facilities afforded to our representative by Mr. H. J. Mills, under whose immediate direction the whole electrical installation has been carried out, and to Mr. W. P. Newling, also of the electrical staff of the exhibition. The exhibition is to be opened on Thursday next, May 14th, by the Prince of Wales, and it is hoped that the King and the President of the French Republic will pay State visits.

Telephony in Canada.—A Reuter's telegram states that in the Saskatchewan Legislative Assembly, the Provincial Government has announced that the Bell Telephone Co. is willing to sell its system in the province to the Government.

The Institution of Civil Engineers.—At the annual general meeting of the Institution of Civil Engineers, held on Tuesday evening, April 28th, the result of the ballot for the election of officers was declared as follows:—President: Mr. James Charles Inglis. Vice-Presidents: Mr. W. R. Galbraith, Mr. G. H. Hill, Mr. A. Siemens, and Mr. W. C. Unwin. Other Members of Council: Mr. J. A. F. Aspinall (Liverpool), Mr B. H Blyth (Edinburgh), Mr. C. A. Brereton, Mr. W. B. Bryan, Mr R. Elliott-Cooper, Colonel R. E. B. Crompton, C.B., Dr. G. F. Deacon, Dr. F. Elgar, Mr. M. Fitzmaurice, C.M.G., Mr. A. T. Grant-Dalton (South Africa), Mr. R. A. Hadfield (Sheffield), Dr. C. A. Harrison (Newcastle-on-Tyne), Mr. J. Hobson (Canada), Mr. W. Hunter, Mr. G. R. Jebb (Birmingham), Sir Wm. Thomas Lewis, Bart. (Aberdare), Sir George T. Livesey, Mr. A. G. Lyster (Liverpool), Mr. Thos. Matthews, Mr. A. B. Moncrieff (Australasia), Mr. A. Ross, Mr. J. H. Ryan (Dublin), Mr. J. Strain (Glasgow), Sir Frederick R. Upcott, K.C.V.O. (India), Mr. W. B. Worthington (Derby), and Mr. A. F. Yarrow. This Council will take office on the first Tuesday in November, 1908. The Council have made the following awards for Papers read and discussed before the Institution during the past session:—A Telford Gold Medal to Mr. W. Barclay Parsons (New York), for his Paper on the New York Rapid Transit Subway (see ELECTRICAL ENGINEERING, March 12th, page 394); a Watt Gold Medal to Sir Whately Eliot; George Stephenson Gold Medals to Sir John Ottley, K.C.I.E., Dr. A. W. Brightmore, and Messrs. J. S. Wilson and W. Gore; Telford Premiums to Messrs. F. W. Davis (Darlington), C. R. S. Kirkpatrick (Newcastle-on-Tyne), Hugh T. Ker (Glasgow), G. H. Scott, R. R. Gales, F.C.N. (India), and S. H. Ellis.

Electric Driving in Cotton Mills.—Messrs. Marples, Leach & Co., Ltd., announce that they have secured the contract for the complete equipment of the new mill being erected by the Tyne Ring Spinning Co., Ltd., at Littleborough, near Manchester. This equipment consists of a complete generating plant, including a 1,200 kw. three-phase steam turbo-generator at 50 cycles, 400 volts, a pilot lighting set, condensing plant with electrically-driven pumps, two 400 h.p. three-phase induction motors at 485 r.p.m., two 100 h.p. motors at 360 revs. per minute, one 50 h.p. motor at 360 revs. per minute, and a number of smaller motors. The larger motors will be direct coupled to the driving shafts on the different floors, while the smaller ones will be connected by ropes or belts to the machines which they have to drive. An elaborate engine-room switchboard is being provided for controlling the whole of the power and lighting circuits in the mill, the main lighting circuits being divided into three sets, equally balanced over the three phases, and will be at 230 volts. The contract includes the supply, delivery, and erection of the whole plant, including the wiring throughout. This section of the work, however, Messrs. Marples, Leach & &o., Ltd., will sub-let to local contractors.

Electrical Lectures at the Manchester Municipal School of Technology.—The syllabus of summer evening courses at the Manchester Municipal School of Technology contains particulars of a special course of six lectures on short circuits, which will be given by Dr. E. Rosenberg, and a course of six lectures by Dr. C. C. Garrard on the principles of electrical control. An investigation on the behaviour of insulators, switchgear, &c., on pressures up to 100,000 volts, is in hand under the direction of Prof. A. Schwartz and Mr. J. Lustgarten, in which a limited number of students will be allowed to take part. Other lecture courses comprise "Alternating-current Transmission Problems," by Mr. C. F. Smith; "Electrical Testing," by Mr. A. E. Moore; "Magnetic Measurements," by Mr. W. H. N. James; "Detail Tests on Electric Supply Meters," by Mr. W. Grant; "Photometric Measurements," by Mr. F. Shaw; and "Diseases of Dynamos and Motors," by Mr. J. Davies. The Physical and Electrochemical Laboratories are under the charge of Prof. W. W. H. Gee, Mr. Adamsen, Mr. Butterworth, Mr. J. Bleakley, and Mr. F. Brotherton.

THE LIFE AND WORK OF LORD KELVIN

The First "Kelvin" Lecture before the Institution of Electrical Engineers

AT the meeting of the Institution of Electrical Engineers last Thursday, Professor Silvanus P. Thompson, F.R.S., delivered the first "Kelvin" lecture. It may be recalled that these lectures, which will be given annually, form part of the memorial to Lord Kelvin, which was recommended by a committee of the Institution in February. The other recommendation was the erection of the statue in a prominent position in London.

Prior to the lecture by Prof. Thompson, Mr. H. F. Parshall presented the Institution with a bronze bust of Benjamin Franklin on behalf of the American Institute of Electrical Engineers. We report the presentation elsewhere.

On December 17th, 1907, aged 83 years, died William Thomson, Baron Kelvin of Largs, when President for the third time of the Institution of Electrical Engineers.

Adequately to set forth the life and work of a man who so early won, and who for so long maintained, the foremost place in the ranks of science, were a task that is frankly impossible; but if we may not attempt the impossible, we may, at least, essay the task of setting down in simple fashion some account of those things which he achieved in the profession represented by this Institution of Electrical Engineers. Let me first set down in briefest outline a sketch of his early life. William Thomson was born on June 26th, 1824, in Belfast, being the second son of James and Margaret Thomson. James Thomson, who was at that time professor of mathematics in the Royal Academic Institute of Belfast, was the son of a small farmer at Ballynahinch, in Co. Down, where his ancestors had settled about the year 1640, when they migrated from the Lowlands of Scotland.

In 1830, when William was six years old, his mother died. His father would never send his boys to school, but taught them himself. In 1832, when William was eight years old, Prof. James Thomson was offered the Chair of Mathematics at Glasgow, and he, and his family of six children, accordingly removed from Belfast. After his removal to Glasgow he still kept the education of his sons in his own hands; and so it happened that in 1834 William Thomson matriculated when in his eleventh year, as a student in the University, without ever having been at school. He early made his mark by his progress in mathematics and physical science, and in 1840 produced an essay, "On the Figure of the Earth," which won him the University medal. His fifth year as student at Glasgow (1839-40) was notable for the impulse towards physics which he received from the lectures of Prof. J. P. Nichol, and from those of David Thomson, a relation of Faraday, who temporarily took the classes in natural philosophy during the illness of Prof. Meikleham. In this year William Thomson had systematically studied the "Mécanique Analytique" of Lagrange and the "Mécanique Celeste" of Laplace, both mathematical works of a high order, and he made the acquaintance—a notable event in his career—of that remarkable book, Fourier's "Theorie de la Chaleur." He borrowed it from the College library, and in a fortnight he had read it completely through. The effect of reading Fourier dominated his whole career thenceforward. He took the book with him for further study during a two months' visit to Germany. During his last year (1840-41) at Glasgow he communicated to the Cambridge and Dublin *Mathematical Journal*, under the signature of "P. Q. R.," an original paper on "Fourier's Expansion of Functions in Trigonometrical Series," which was a defence of Fourier's deductions against some strictures of Prof. Kelland.

He left Glasgow University after six years of study without even taking his degree; and on April 6th, 1841, entered as a student at St. Peter's College, Cambridge. Here he speedily made his mark, and continued to contribute, at first anonymously, to the Dublin and Cambridge *Mathematical Journal*, papers inspired by his study of the higher mathematics and by his love for physics. The analogy of the movement of heat in conductors along lines of flow, and across surfaces of equal temperature, with the distribution of electricity of conductors in such a way that the lines of electric force were crossed orthogonally by surfaces of equi-potential, led to his paper entitled "The Uniform Motion of Heat in Homogeneous Solid Bodies and its Connection with the Mathematical Theory of Electricity." He also formed a close friendship with Stokes, then a young tutor, with whom, until his death in 1902, he maintained a continual interchange of ideas and suggestions in mathematical physics.

Of Thomson's Cambridge career so much has been written of late that it will be very briefly treated here; how he went up for his Tripos in 1845; how he came out Second Wrangler only, being beaten by the rapid Parkinson, and how he beat Parkinson in the Smith's prize competition.

On leaving Cambridge with a college fellowship of £200 a year to maintain him, Thomson went to Paris and worked in the Laboratory of Regnault at the College de France. He was here four months, and made the acquaintance of Biot and of Sturm and Foucault, of whom he spoke in terms of admiration. Thomson was about 21 years old, and had already established for himself a growing reputation for his mastery of mathematical physics. He had published about a dozen original papers, and had experience in three Universities. In 1846, the Chair of Natural Philosophy at Glasgow became vacant by the death of Prof. Meikleham, and Thomson, at the age of 22, was chosen to fill it. This professorship he continued to hold until he resigned it in 1899, after continuance for 53 years. The old College buildings where he lectured and worked for 24 years were ill-adapted for any laboratory facilities, yet he contrived to organise a physics laboratory, the first of its kind in Great Britain, in some disused rooms in a dark corner of one of the quadrangles. In the lecture theatre his intense enthusiasms won for him the love and respect of all students, even those who were hopelessly unable to follow his frequent flights into the more abstruse realms of mathematical physics.

The next few years were years of strenuous work, fruitful in results. By the end of 1850, when he was 26 years of age, he had published no fewer than fifty original papers, mostly highly mathematical in character, and some of them written in French. Amongst these researches there is a remarkable group which originated in his attendance in 1847 at the meeting of the British Association. He had prepared a paper on the exceedingly excellent method, discovered by himself, of treating certain problems of electrostatics by the method of electric images. A more important event was the commencement of his friendship with Joule, whom he met here for the first time. In 1840 Joule had already communicated to the Royal Society a paper on the production of heat by voltaic electricity. He also read papers at the British Association meetings on the "Electric Origin of Chemical Heat" at Manchester in 1842; "On the Calorific Effects of Magneto Electricity," and "On the Mechanical Value of Heat" at Cork in 1843; "On Specific Heat" at Harrogate in 1844; and on the "Mechanical Equivalent of Heat" at Cambridge in 1845. At that time, when there was as yet no doctrine of the conservation of energy, Joule's work was listened to with impatience, and his teachings fell on deaf ears. But Thomson threw himself heart and soul into the new and strange doctrines that heat and work were mutually convertible, though at first he found difficulty in grasping its significance, and for the next six or eight years, partly in co-operation and partly independently, he set his unique powers of mind to unravel those mutual relations. Thomson's mind was essentially metrical; he was never satisfied with any phenomenon until it should have been brought into the stage where numerical accuracy could be determined. "I often say," he once remarked, "that when you can measure what you are speaking about and express it in numbers, you know something about it." It was in this spirit that he approached the subject of the transformation of heat. Temperatures had hitherto been measured by arbitrary scales based on the expansion of quicksilver or of air or other gas, and the quicksilver thermometer scale did not agree precisely with that of the air thermometer. In January, 1848, he communicated to the Cambridge Philosophical Society a paper on "An Absolute Thermometric Scale founded on Carnot's Theory and the Motive Power of Heat Calculated from Regnault's Observations." In this paper he set himself to answer the question, "Is there any principle on which an absolute thermometric scale can be founded?" and arrived at the answer that such a scale is obtained in terms of Carnot's theory, each degree being determined by the performance of equal quantities of work in allowing one unit of heat to be transformed in being let down through that difference of temperature. This indicates as the absolute zero a temperature the point of which would be marked as $-273°$ on the air thermometer scale. Thomson continued to work at the

Digitized by Google

subject. He experimented on the heat developed by compression of air, and he verified the singular prediction of his brother, Prof. James Thomson, of the lowering by pressure of the melting point of ice. He gave a thermodynamic explanation of the non-scalding property of steam issuing from a high pressure boiler, and he formulated in the years 1851-54 with scientific precision in a long communication to the Royal Society of Edinburgh the two great laws of thermo-dynamics. In collaboration with Joule, he worked on the thermal effects of fluids under motion, the results appearing between the years 1852–62 in a series of four papers in the *Philosophical Transactions*, and four others in the *Proceedings* of the Royal Society. Thus were the foundations of thermodynamics laid.

In 1852, at the age of 28, William Thomson married Margaret Crum, and resigned his Cambridge fellowship. The happiness of his life was, however, shadowed by his wife's precarious health necessitating residence abroad at various times, and it was at Kreutznach that he made the acquaintance of Professor Helmholtz. A year later Helmholtz again met the Thomsons at Schwalbach. Writing to his father, he described Thomson as certainly one of the finest mathematical physicists of the day, with powers of rapid invention such as I have seen in no other man.

Hitherto, Thomson's work had been mainly in pure science, but towards the end of the fifties, while still in the midst of his thermodynamic studies, events were progressing, which drew him with irresistible force towards the practical applications that made him famous. Indeed, it could hardly be otherwise, seeing that he was a master of whatever he touched. Early in 1853 he had communicated to the Glasgow Philosophical Society a Paper on "Transient Electric Currents," in which he investigated mathematically the discharge of a Leyden jar through circuits possessing self-induction as well as resistance. Faraday and Riess had observed that in certain cases the gases produced by the discharge of sparks through water consisted of mixed oxygen and hydrogen, and Helmholtz had conjectured that in such cases the spark was oscillatory. Thomson determined to test mathematically what was the motion of electricity at any instant after making contact in circuit under given conditions. The result was very remarkable. He discovered that a critical relation occurred when the capacity in the circuit was equal to four times the co-efficient of self induction divided by the square of the resistance. If the capacity was less than this, the discharge was oscillatory, passing through a series of alternate maxima and minima before dying out. If the capacity was greater than this, the discharge was non-oscillatory, the charge dying out without reversing. This beautiful bit of mathematical analysis, which passed almost unnoticed at the time, laid the foundation of the theory of electric oscillations subsequently studied by Overbeck, Schiller, Hertz, and Lodge, and forms the basis of wireless telegraphy.

At the Edinburgh meeting of the British Association in 1854, Thomson read a Paper on "Mechanical Antecedents of Motion of Heat and Light," in which he touched upon the source of the sun's heat and the energy of the solar system, and reverted to his favourite argument from Fourier, according to which, if traced backwards, there must have been a beginning to which there was no antecedent. This was a non-mathematical exposition of work which, as his note-books show, had been going on from 1850 in a very stiff mathematical form, in which Fourier's equations for the flow of heat and solids were applied to a number of outlying problems, including the diffusion of fluids and the diffusion or transmission of electric signals through long cables. He communicated with the Royal Society in 1854 a general investigation of cables under the title, "On the Theory of the Electric Telegraph."

Faraday had predicted that there would be retardation of signals, owing to the coating of gutta-percha acting like the glass of a Leyden jar. Constructing the appropriate differential equation, and using Fourier's integration of it, Thomson drew the conclusion that the time required for the current at the distant end to reach a stated fraction of its steady value would be proportional both to the resistance and the capacity; and as both of these are proportional to the length of the cable, the retardation would be proportional to the square of the length. This is the famous "law of squares" about which so much dispute arose. This Paper was followed by a further research on peristaltic induction of electric currents, communicated to the British Association in 1855, and afterwards in a more mathematical form to the Royal Society. Submarine telegraphy was "in the air."

John and Jacob Brett had pioneered the project for a Dover-Calais cable, and in 1851 Crampton successfully joined England and France. In 1853 Holyhead and Howth were connected by Mr. (later Sir) Charles Bright, and these were followed by the Dover-Ostend and longer cables. Cyrus Field, in 1856, negotiated a cable across the Gulf of St. Lawrence, thus connecting Newfoundland to the American continent. The Atlantic Telegraph Co. was formed to promote a great enterprise to join Ireland and Newfoundland. Field, Brett, Bright, Statham, and Wildman Whitehouse were the chief promoters. Bright was engineer, and Whitehouse, a retired Brighton doctor, was the electrician. In a pamphlet issued by the company in 1857, the statement is made that the scientific world is particularly indebted to Prof. William Thomson for the attention he has given to the theoretical investigation of the conditions under which electric currents move in long insulated cables, and Mr. Whitehouse has had the advantage of this gentleman's presence at his experiments and his counsel upon several occasions. This is one side of the matter. The other side is that Mr. Whitehouse had at the British Association meeting of 1856 read a Paper challenging the law of squares, and declaring that if it were true, Atlantic telegraphy was hopeless. The true significance of this was disposed of by Thomson in two letters to the *Athenæum*. He pointed out that success lay, in the first place, in an adequate section of conductor, and hinted at a remedy deduced from Fourier's equations, which he later embodied in the curb signal transmitter. In December, 1856, he described at the Royal Society his plan for receiving messages, viz., a sort of Helmholtz tangent galvanometer with copper damper to the suspended needle, the deflections being observed by watching through a reading telescope the readings on a scale reflected from the polished side of the magnet, or from a small mirror carried by it. As we all know, he abandoned this subjective method for the objective plan in which a spot of light on the lamp is reflected by the mirror upon a scale. The story of the Atlantic cable, of the failure of 1857, and of the brief success of 1858 has so often been told that it need not be repeated here. Thomson, after the failure of the first attempt, was called upon to take a more active part, and was put in charge of the test-room on board the *Agamemnon* in 1858. Whitehouse was unable to join this expedition, and Thomson, at the request of the directors, undertook the post of electrician-in-charge, without any recompense. After various disheartening mishaps success crowned their efforts. Throughout the voyage, the Thomson mirror galvanometer had been used for the continuity tests, and for signalling to shore with a battery of 75 Daniell cells. The continuity was reported perfect, and the insulation had improved on submersion. On August 5th the cable was handed over to Mr. Whitehouse, and reported to be in perfect condition. Whitehouse at once abandoned the Thomson mirror instrument, and began practising with his own special patented apparatus, using heavy currents and a special transmitter with induction coils. After about a week the reflecting galvanometer and Daniell cells were resumed, and international congratulations were exchanged. But the insulation was found to be giving way, and on October 20th, after 732 messages had been conveyed, the cable spoke no more. It had been destroyed by Whitehouse's use of induction coils, 6 ft. in length, working at some 2,000 volts.

Of the part played by Thomson during the next eight years there is little to speak. Suffice it to say that when the new cable was laid, and the last one recovered and completed, Thomson was the ruling spirit, whose advice was cordially sought and followed. On his return he was knighted for the part he had played so well. He had in the meantime made further improvements in conjunction with Cromwell Varley. In 1867 he patented the siphon recorder, and in conjunction with Fleeming Jenkin, the curb transmitter. Besides all this telegraphic work, he was incessant in research. He had undertaken a series of investigations on the conductivity of copper, he was urging the application of improved systems of metric measurements and the adoption of rational units, and on his initiative was formed the famous Committee on Electrical Standards of the British Association, which, year by year, has done so much to carry to perfection the standards and methods of electric measurement. So early as 1851 he had begun to use the absolute system.

Amongst the activities of these fruitful years was a long research on the electro-dynamic qualities of metals—thermo-electric, thermo-elastic, and thermo-magnetic. This formed the subject of his Bakerian lecture of 1856. He also worked hard at the mathematical theory of magnetism. Faraday's work on diamagnetism had appeared whilst Thomson was a student at Cambridge. It established the fact that magnetic forces were not mere connections at a distance between supposed poles, but connections dependent on the surrounding medium, and Thomson set himself to investigate the matter mathematically. To Thomson we owe the terms "permeability" and "susceptibility" so familiar in the consideration of the magnetic properties of iron and steel.

Digitized by Google

In 1859-60 Thomson was studying atmospheric electricity, and for this study he invented the water-dropping collector, and vastly improved the electrometer, which developed into the elaborate forms of quadrant instruments and other types described in the British Association report of 1867. During this work he discovered the fact that the sudden charge or discharge of a condenser is accompanied by a sound; he also measured electrostatically the electromotive forces of a Daniell cell, and investigated the potential required to give a spark of different lengths in air. In these years Thomson was also writing on the secular cooling of the earth and investigating the changes of form during rotation of elastic spherical shells, and if this were not enough to have in hand, he embarked, with his friend, Prof. Tait, on the preparation of a text-book on natural philosophy. In 1867 he communicated to the Royal Society of Edinburgh his famous Paper on "Vortex Atoms." Though he seemed at the end of his life to doubt whether the vortex atom hypothesis was adequate to explain all the properties of matter, the conception remains for all time a witness to his extraordinary powers of mind.

In the winter of 1861 William Thomson met with a severe accident. He fell on the ice when engaged in the pastime of curling, and broke the neck of his thigh. For several months he had to lie on his back, and it was at this time that he adopted the famous green note books which for ever afterwards were the companions of his days. In 1870 Lady Thomson died. In the same year the University of Glasgow was removed to the new buildings on Gilmore Hill. Sir William Thomson had a house here adjoining his laboratory and lecture room.

From his youth he had been fond of the sea, and had early owned boats of his own on the Clyde. For many years his sailing yacht, the *Lalla Rookh*, was conspicuous, and he was an accomplished navigator. His experiences in cable laying had taught him much, and in return he was now to teach science in navigation. First he reformed the mariners' compass; and, dissatisfied with the clumsy appliances used in sounding, he devised the well-known apparatus for taking flying soundings by using a line of steel piano wire. He was vastly interested in the question of the tides, not merely as a sailor, but because of the interest attending the mathematical treatment in connection with problems of the rotation of spheroids. He invented a tide predicting machine, and adopting the beautiful mechanical integrator, the device of his brother, Prof. James Thomson, he invented a harmonic analyser.

In 1874 Sir William Thomson married Miss Frances Anne Blandy, of Madeira, whom he met on one of his cable-laying expeditions. Lady Kelvin, who survives him, became the centre of his home in Glasgow, and the inseparable companion of all his later travels. He built at Netherhall, Largs, a mansion in the Scottish baronial style; and though latterly he had a London house in Eaton Place, Netherhall was the home to which he retired when he withdrew from active work in the University of Glasgow.

Throughout the seventies and eighties Sir William Thomson's scientific activities were continued with untiring zeal. In 1874 he was elected President of the Society of Telegraph Engineers and Electricians, of which, in 1871, he had been a foundation member and vice-president. In 1876 he visited America, bringing back with him a pair of Graham Bell's earliest experimental telephones. He was President of the Mathematical and Physical Section of the British Association that year at Glasgow.

With the advent of electric lighting at the end of the seventies, Thomson's attention was naturally attracted to this branch of the practical applications of science. He never had any prejudice against the utilisation of science for practical ends, and so he scorned not to devise instruments and applications for commercial use. His electrometers, his galvanometers, his siphon recorders, and his compasses, had been made by James White, of Glasgow. In this firm he became a partner, taking the keenest commercial interest in its operations. He gave evidence before a Parliamentary Committee on electric lighting, and discussed the theory of the electric transmission of power, pointing out the advantages of high voltages. In his Presidential Address to the Mathematical and Physical Section of the British Association at York, he spoke of this and of the possibility of utilising the powers of Niagara. He also read two papers, in one of which he showed mathematically that in a shunt dynamo the best economy of working was attained when the resistance of the outer circuit was a geometric mean between the resistance of the armature and of the shunt. In the other he laid down the famous law of economy of copper losses for the transmission of power.

Lord Kelvin's patented inventions were very numerous. Without counting all those since 1900, taken mostly in the name of Kelvin and James White, they numbered 56. Of these, 11 relate to telegraphy, 11 relate to compasses and navigational apparatus, 6 to dynamo machines or electric lamps, 25 to electric measuring instruments, 1 to the electrolytic production of alkali, and 2 to valves for fluids. He was an independent inventor of the zigzag method of winding alternators, which was published under the name of Ferranti's machine, which was manufactured under royalties payable to him.

In 1884 he was revolving over the speculations which later in the same year he was to pour out in such marvellous abundance in his famous twenty lectures at Baltimore on "Molecular Dynamics and the Wave Theory of Light." All his life he had been endeavouring to discover a mechanical explanation for the most recondite phenomena. While Thomson had been seeking to explain electricity, magnetism, and light dynamically, Maxwell had boldly propounded the electromagnetic theory of light. Thomson had never accepted Maxwell's theory. It is true that in 1888 he gave a nominal adhesion, but later he withdrew this, preferring to think of things in his own way. Once Lord Kelvin astonished an audience at the Royal Institution by a discourse on "Isoperimetrical Problems," intended to give a popular account of the mathematical process for determining maxima and minima. On another occasion he entertained the Royal Society with a discourse on the homogeneous partition of space in which the fundamental packing of atoms was geometrically treated.

To the last Lord Kelvin took an intense interest in the most recent discoveries. Electrons, or "electrions," as he called them, were continually under discussion. He prided himself that he had read Rutherford's book on radioactivity again and again, but objected, however, *in toto*, to the notion that the atom was capable of division or disintegration. After taking part in the British Association meeting of 1907, at Leicester, where he entered with surprising keenness into the discussions on radioactivity and kindred questions, he went to Aix-les-Bains for change. He had barely reached his home at Netherhall in September when Lady Kelvin was struck down with a paralytic seizure. Shortly afterwards a chill seized him, and after about a fortnight of prostration he sank slowly and quietly away. He was buried in Westminster Abbey with national honours on December 23rd, 1907. Our sympathies go out to the gracious lady who survives him, and who with such assiduous devotion tended him in his declining years.

Honours fell thickly on Lord Kelvin in his later life. He was President of the Royal Society from 1890 to 1894; he was raised to the peerage in 1892; he was one of the original members of the Order of Merit founded in 1902; was a Grand Officer of the Legion of Honour; and held the Prussian Order *Pour le Mérite*. In 1904 he was elected Chancellor of the University where he had held the Chair of Natural Philosophy for fifty-three years. He had celebrated his jubilee with unusual marks of world-wide esteem in 1896, and finally retired in 1899.

Kindly hearted, lovable, modest to a degree almost unbelievable, he carried through life the most intense love of truth and an insatiable desire for the advancement of natural knowledge. We of this Institution may well be proud of him; proud that he was one of our first members, that he was thrice our President, and that as our President he died. We shall not look upon his like again.

SIR WILLIAM PREECE, K.C.B., F.R.S., in proposing a vote of thanks to Prof. Thompson, said he would be voicing the feelings of everyone present when he said they had enjoyed a delightful hour and a half in listening to the reading of one of the best digested memorials that he had ever listened to, couched in the simplest and most beautiful language, of which Prof. Thompson was a master, touched up with brilliant flashes of scientific truths, and giving an idea of the work of that great man, which otherwise they would have great difficulty in condensing within their own minds. Dr. Thompson had also made the lecture agreeable because he had given delightful little touches of humour which did away with any conception of the lecture being a kind of doleful memorial, and which had left the impression of being a witty and sensible expression of his admiration of the great life which had gone. He himself stood there as one who for over half a century claimed an intimate knowledge and acquaintance with their great chief, but he would not take advantage of the opportunity to say a word of his own feelings in this matter, but would simply say that as a man while Lord Kelvin lived he loved him, and now that he was dead he revered him. It was his duty to propose "That a vote of thanks be accorded to Prof. Silvanus Thompson for the address we have listened to, and to ask his permission for the lecture to be given in the journal of our *Proceedings*."

Prof. F. CAREY FOSTER said he felt it a great honour to second the vote of thanks. To speak at all adequately on the subject in the short time allowed was no easy task, and he thought they must all recognise that Prof. Thompson had most worthily fulfilled that difficult task. He could not quite equal Sir William Preece in claiming half a century's friendship with Lord

Digitized by Google

Kelvin, but he could go near to it. He first had the honour of making his acquaintance in 1862, and he would never forget the kindness and generosity which he always showed to younger men. One of the things which he remembered most was his generous appreciation of work which he considered was genuine and true of its kind. Another small point that he might perhaps refer to, in confirmation of Prof. Thompson's lecture, was in regard to mathematical discussions of physics. Lord Kelvin was never satisfied with any mathematical expressions which could not be reduced to arithmetical calculations; a problem, to him, was not solved until it could be reduced to arithmetic. They had heard of his enormous activity; work which any other man would have broken down under; but he was never too full of his own business to be unable to give attention to any claim upon him from others. This was another example of his enormous generosity and kindness. His own thoughts went back to him even more as a man than as an illustrious leader of science, but in both aspects it was a memory that not only they, but the whole nation, might be proud of. They had to thank Prof. Thompson for the most excellent account of this great man whose loss they all feelingly deplored.

PRESENTATION FROM THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS

AT the Institution of Electrical Engineers on Thursday, Mr. H. F. Parshall presented, on behalf of the American Institute of Electrical Engineers, a bronze bust of Benjamin Franklin. Mr. Parshall, who is local honorary secretary of the American Institute, said it was his duty and pleasure to make the presentation of this souvenir of the happy remembrances of a trip to England about a year and a half ago. As it would be recalled by those knowing more particularly the circumstances, it was intended to present this on what, perhaps, would have been the most auspicious occasion that could have been in an electrical engineer's life, viz., when Lord Kelvin honoured them by consenting to sit in the chair during the present session. That, alas, was not to be. Both Lord and Lady Kelvin had seen the bust, however, and he had received a note from Lord Kelvin expressing his appreciation and also his admiration of it. When he received a letter from the American Institute of Electrical Engineers, asking him to make this presentation, it stated that the subject was Franklin, and he took the greatest pleasure in making the presentation, since it seemed to him that no more appropriate subject could be found. Franklin, as was admitted both in this country and his own, was the greatest natural philosopher that had been produced on the other side of the Atlantic; Kelvin, they were all glad to admit, was the greatest on either side of the Atlantic; greater than Franklin so far as natural endowments were concerned; greater as a scientist; but still, each the greatest produced in their own continent. So far as Franklin was concerned, it was reasonably stated that he was a British subject; he was, to all intents and purposes. So far as name went, and so far as the name of all principal American scientists went, he was British, but that, they thought, in America in no way detracted. They were only proud that they were British, proud that there was that common ground between them. He therefore requested the Institution of Electrical Engineers to accept the bust as a sincere token of the friendship and esteem of their American brothers, the American Institute of Electrical Engineers.

COL. CROMPTON (President) said the Institution of Electrical Engineers felt very deeply, indeed, this token of respect on the part of American engineers for our great man, Lord Kelvin. They had to thank Mr. Parshall for the very appropriate and kindly way in which he had spoken, and, although they felt that no man could approach our great Kelvin, they felt that if there was another, it was Franklin. He begged that Mr. Parshall would bear to their brothers in America a message of the warm feeling which was felt for them by the members of the Institution. They would never forget their kindly reception at the hands of the American Institute at the time of the St. Louis Exhibition, and it was a poor return they were able to give when the American Institute visited England a year and a half ago. He only hoped there would be another of these meetings, and that the warm feeling that exists, making the two Institutions practically one, would be continued by more and more frequent meetings, and that they might, in the future as in the past, consider themselves almost one body, the presentation that evening being an additional link tying them together.

Wireless Telegraphy.—It is stated that the Admiralty propose to erect a wireless telegraph station at Stoneywood, Aberdeen.

THE MARSEILLES ELECTRICAL EXHIBITION

IN accordance with our previous announcement, an International Exhibition of the Industrial Applications of Electricity was opened at Marseilles on April 19th by M. Chanot, the Mayor of Marseilles, M. Mastier, Prefect of the Department of Bouches-du-Rhône, and other officials. Although the whole of the exhibitors' stands were not yet quite completed, it was evident that this would soon be remedied, for everything was in an advanced state, and great activity was apparent. *L'Electricien* publishes a plan of the Exhibition, which is being held in the Parc du Rond-Point du Prado. The principal building near the centre of the grounds, the Grand Palais, is devoted to industrial and domestic applications of electricity, and the exhibits are divided into the following sections :— Public and private lighting; electrical heating and ventilation for industrial purposes; electrochemistry, electrometallurgy, and allied industries; telegraphy, telephony, bells, and electric clocks; medical electricity; measuring and controlling apparatus; materials and products utilised in the electrical industry; the teaching of electricity. Another large building, named the *Palais de l'Energie*, is devoted to transport and distribution of electrical energy, and the exhibits are classified as follows :— Applications of electric motive power to industry in general; apparatus for hoisting, loading, and unloading; and applications to military and marine engineering and public works. In a separate building are shown exhibits relating to applications of electricity to mines and quarries, and a large section dealing with electric traction. The applications of electricity to agriculture are also represented in another part of the Exhibition, where experimental installations have been put down. A feature of the Exhibition is a collection of historical electrical exhibits, showing the rapidity with which the electrical industry has advanced, and a very complete library and reading-room is provided, where visitors can consult a large collection of electrical works and current electrical literature.

As already announced, a Congress on the Applications of Electricity will be held at Marseilles in September next, and a considerable number of persons have already signified their intention of taking part.

Animated Photography in Natural Colours.—At Urbanora House, Wardour House, on Friday last, Mr. G. Albert Smith gave a demonstration of his system of animated photography in colour. Briefly, the process is as follows :—The photographs are taken with an ordinary bioscope camera on a film which is sensitive to red and yellow as well as blue light. Alternate photographs are taken through yellowish red and yellowish green screens respectively. The film is developed in the absence of all light, and a positive printed. This positive film is projected on the screen, and the photographs which were taken through the yellowish red screen are projected through a yellowish red screen. The intermediate photographs are projected through a yellowish green screen. Owing to the phenomenon of persistence of vision, the two coloured pictures are superimposed on the retina, and the observer apparently sees a completely coloured picture. The speed of projection is about 32 pictures per second. Three consecutive photographs through red, yellow, and green screens respectively would be preferable, but the high speed to secure all three pictures simultaneously on the retina would be impracticable. With two colours, however, an excellent result is obtained. The building is ventilated throughout by means of electric fans (port-hole extraction and pedestal types), and the offices are heated by electric radiators. All machines are driven by enclosed electric motors with enclosed regulators and switches. The printing and drying machines, and also those for perforating the films, are all driven electrically, and the neat and cleanly appearance of the various rooms in the establishment speaks well for this system of driving. Owing to the inflammable nature of the material dealt with, any form of lighting other than electric would have been distinctly dangerous. The studio is equipped with 14 photographic lamps of 25 amps. each, to burn singly on 214 volts, which are separately controlled and regulated from a special D.P. switch fuse board in the room. The theatre and exhibition rooms are each supplied with two 65-amp. projectors, in addition to the usual apparatus used in theatres. The lighting is extensive and various, consisting as it does of about 200 ruby lamps of 5 c.p., 220 carbon filament lamps of 50 to 8 c.p. and 200 tantalum 80 to 30 c.p. patent tubular lamps. All the wires, cables, &c., are contained in heavy gauge Simplex screwed conduit, and no point in any wire has been permitted throughout the work. A switchboard mounted on white marble with tandem knife switches and tubular fuses, in an oak cabinet frame (which swings on a trolley, so as to enable the connections, &c., at back to be conveniently reached) controls the whole. The entire work and installation has been carried out to the specification, and under the supervision of, Mr. E. H. Johnson, and the material, including switchboards, motors, &c., has been supplied by the E.M.F. Manufacturing Co., 10 Ironmonger Lane.

THE EDISON BATTERY FOR AUTOMOBILES

THE more robust mechanical construction of the Edison alkaline cell is claimed to render it more suitable for use on electric road-vehicles than the ordinary lead accumulator, and although the increased output for a given weight over that of the lead cell is not so great as was at one time expected, yet the output is certainly higher, and there are other advantages which indicate its superiority for automobile work. The Bergmann Elektricitätswerke Akt.-Ges. of Berlin have developed a series of types of electrically-propelled vehicles in which Edison cells are used, and through the courtesy of Messrs. Marples, Leach & Co., of London, who are the sole agents for this country, we are able to give a description of the electrical equipment of some of these cars.

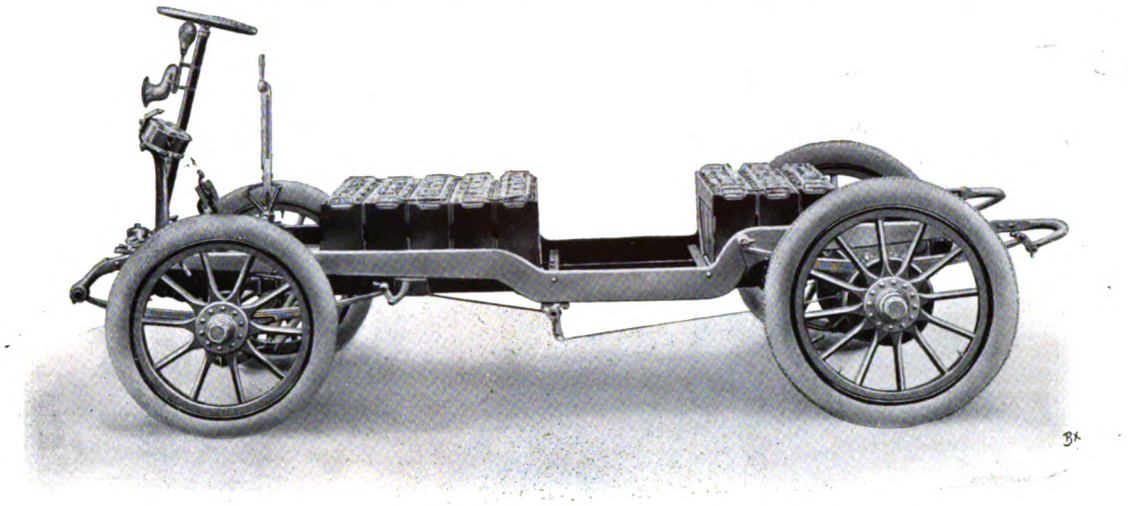

Fig. 1.—Chassis for Landaulette, with Cells arranged under the Seats.

The standard chassis for landaulettes or similar cars for private or public town use is illustrated in Fig. 1. A single motor drives the back axle through single-reduction spur gearing and a differential, the ratio of the gear being 5 : 1. The axles and gear-wheels are of nickel-steel, and roller bearings are provided. The motor has a continuous rating of 5 h.p., but has a one-hour rating of 15 h.p. It is an 80-volt two-pole series motor without interpoles, and runs normally at a speed of 1,500 r.p.m. This chassis can also be obtained with hub-motors in the back wheels, and it is thought by the agents that, in spite of their lower efficiency and the increased weight, these low-speed hub-motors will supersede the single high-speed geared motor for town use.

The crates containing the cells are arranged under the seats, as can be seen from Fig. 1. The number of cells is 64. Each cell has a capacity of 175 ampere-hours, and an average pressure of 1·23 volts. The total capacity of the battery is thus 14 kilowatt hours, or 11 watt hours per lb., which is somewhat higher than the capacity of a lead battery of equal weight. The construction of the cell is shown in Figs. 2, 3, and 4. The nickel-steel plates in which are inserted the perforated steel pockets containing the iron or nickel oxide are assembled and bolted together with a surrounding ebonite frame, as shown in the figures. These cells are manufactured by the German Edison Accumulator Co., and the mechanical design and the composition of the active material are almost exactly the same as of those exhibited at the St. Louis Exhibition in 1904. At any rate, cobalt is not used in the composition for these cells. The electrolyte is a caustic potash solution, and under normal conditions of working the cells should be filled up with distilled water every three weeks. The normal charging current is about 65 amperes, and the charging takes about 3¾ hours. Messrs. Marples, Leach & Co. supply a special filling apparatus. The nozzle of a flexible tube is inserted in the opening provided at the top of the cell, and as soon as the water reaches the tip of this nozzle, an electric circuit is completed and a bell rings. Each cell weighs complete between 18 and 19 lb., and as the cells are arranged in sets of 8 in wooden trays, each tray weighing 160 lb., the battery can be readily removed if necessary. The cells, however, do not require washing out, as it is impossible for any sediment to form at the bottom of the cases. One advantage of the Edison cell is that no objectionable gases are given off during either charging or discharging. The car equipped with the above 64-cell battery can make a run of 56 miles on a level road with a single charge. The maximum speed on the level is about 16 miles per hour.

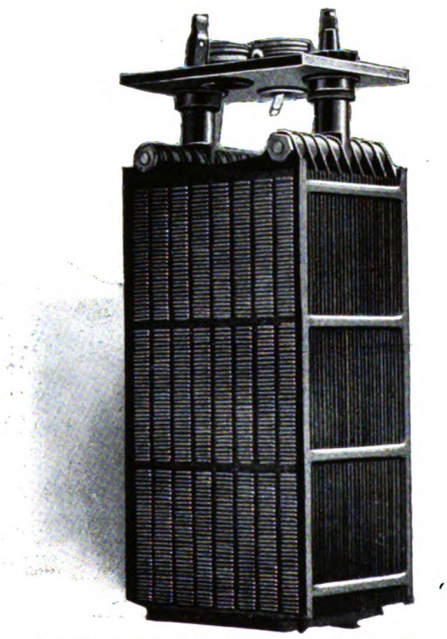

Fig. 2.—Assembled Plates of Edison Cell.

The method of control is very simple, and is as follows:—The battery is divided into two halves, and the series field-winding is also in two halves. On the first

Digitized by Google

step of the controller at starting the two halves of the battery are in parallel and the two fields in series; a starting resistance is also in circuit. On the second step the starting resistance is short-circuited. On the third step the two series fields are put in parallel. The two halves of the battery are put in series on the next step with the fields in series, and on the fifth and last step, corresponding to the highest speed, the two halves of the battery are in series and the two series fields are in parallel. The two halves of the battery are in parallel for both backward running steps; the fields are, however, in series and parallel respectively. A series coil for the magnetic blow-out is provided. A new control system has already been designed, in which the regenerative principle will be employed. With regenerative control it is expected that the mileage of the car will be increased to the amount of 15 to 30 per cent. of its present value.

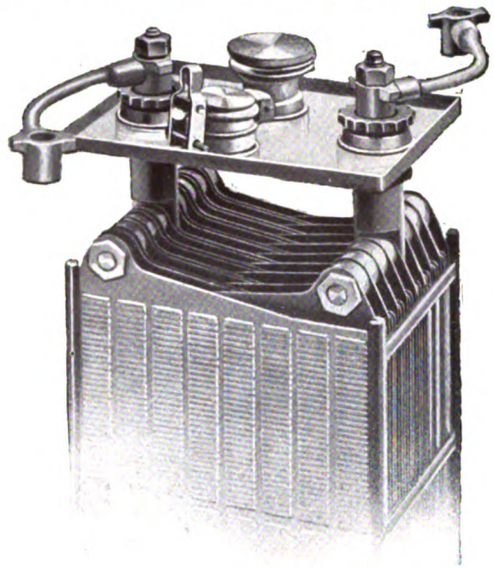

Fig. 3.—Arrangement of Plates and Terminals.

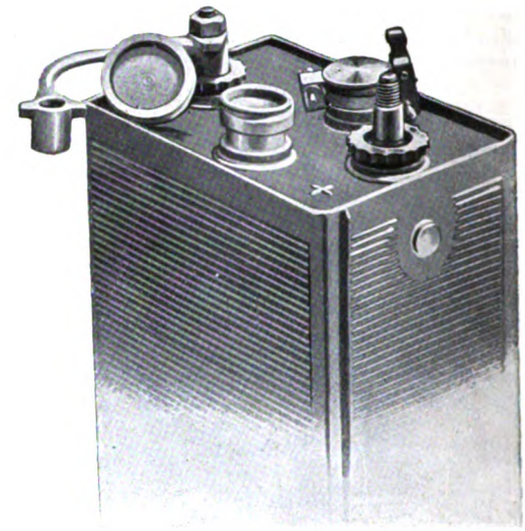

Fig. 4.—Outer Case of Cell.

Besides the light cars of the above type, the company also supplies several types of heavy vehicles. The chassis for a two-ton delivery waggon is illustrated in Fig. 5. It will be noticed that here again only one motor is employed. The motor is geared to an auxiliary axle through differential gearing, and this axle is connected to the back wheels through a chain drive. The battery is suspended from the chassis in a large box, as illustrated in Fig. 5. This two-ton waggon attains a speed of 7½ miles per hour on the level, and with a single charge of 64 cells can cover a distance of 40 miles. The one-ton waggon attains a speed of 12 miles per hour, and covers a distance of 56 miles on one charge. The five-ton waggon is equipped with two motors. The company actually recommends the use of iron tyres for their heavy vehicles, which speaks well for the mechanical construction of the cells.

Experience has shown that the maintenance and repair expenses are remarkably low for these electrically-driven waggons, and the following figures for the cost of running are of interest:—The landaulette car consumes about 120 watt-hours per ton mile, fully loaded and on level roads. If the price of electrical energy is 2d. per unit, this is equivalent to a ½d. for the cost of energy consumed per ton mile, assuming a battery efficiency of 80 per cent. The weight of the chassis illustrated in Fig. 1, with motor but without battery, is 14 cwt. With battery the weight is 25 cwt. The weight of the complete car with motor, battery, body, and all necessary gear is 30 cwt. The car is provided with three brakes, two on the back wheels and one on the motor shaft. No means of braking electrically are provided at present, but, of course, the new regenerative control arrangement provides for this. Messrs. Marples, Leach & Co. are at present moving out of their premises in Victoria Avenue to a larger building in Artillery Lane, E.C., where increased garage accommodation will be available.

SOME LARGE TELEPHONE CABLES

We illustrate below two large telephone cables made by the British Insulated & Helsby Cables, Ltd. Fig. 1 shows, full size, an 800-pair (1,600 wire) cable made of such a size that it can be drawn into a standard 3-in. pipe. Several miles of this cable are in use by the National Telephone Co. and various Colonial and foreign administrations. The conductors weigh 10 lb. per mile, *i.e.*, they are between 22 and 23 S.W.G. Each conductor is insulated by a single layer of manilla paper, applied spirally; the longitudinal method of wrapping with a whipping of thread is only employed for wires of 40 lb. per mile and upwards.

In the earlier telephone cables two layers of paper were almost invariably employed, but it is now found that the single layer is sufficiently strong mechanically, and that, owing to the tighter laying up of the wires that is necessary if the thickness is increased by the second layer of paper, and the fact that the specific inductive capacity of paper is higher than that of air, the cable with the single layer of paper on each wire has a lower capacity and is therefore better for telephonic purposes, in addition to being cheaper. The paper-insulated wires are laid up into pairs and then stranded, the centre core having five pairs and each successive layer six more pairs than the previous one. The lead sheath is 125 mils. in thickness, bringing the outside diameter and the whole cable to 2·625 ins. The lead contains 3 per cent. of tin, which has the effect of hardening it slightly; this is generally considered advisable in large paper-insulated telephone cables on account of the relatively small internal support afforded by the air-space cable. An average wire-to-wire capacity of 0·07 m.f. per mile is obtained and a maximum of 0·08 m.f. per mile. This is extremely low when it is considered how close the wires must be packed to enable 1,600 of them to be contained in a $2\frac{5}{8}$-in. lead tube.

The cable is usually supplied in lengths of 150 to 200 yards; its weight is about 20 tons per mile.

Fig. 1.—800-pair Lead-covered Telephone Cable. Full Size.

Fig. 2 is a full-sized section of a composite telegraph and telephone cable of a type referred to by Mr. F. Tremain in his recent instructive Paper read before the Newcastle Local Section of the Institution of Electrical Engineers (*see* Electrical Engineering of April 2nd, 1908, p. 519). Considerable quantities of this cable are in use by the Post Office on their underground routes, and on one occasion, we are informed, a length of 13 miles, for the section between Bath and Bristol on the Post Office western underground route, was delivered within seven weeks of the receipt of the order. This cable was laid and jointed by the Post Office engineers without a single fault developing throughout its length.

The cable illustrated contains fifteen pairs of 150 lb. twin conductors, seven quadruple pairs or "quads" of eight conductors each weighing 100 lb. per mile, six pairs of 100 lb. conductors; twenty-two single "screened" conductors weighing 200 lb. per mile, for telegraph purposes, and forty-two single-screened 70 lb. conductors—162 wires in all.

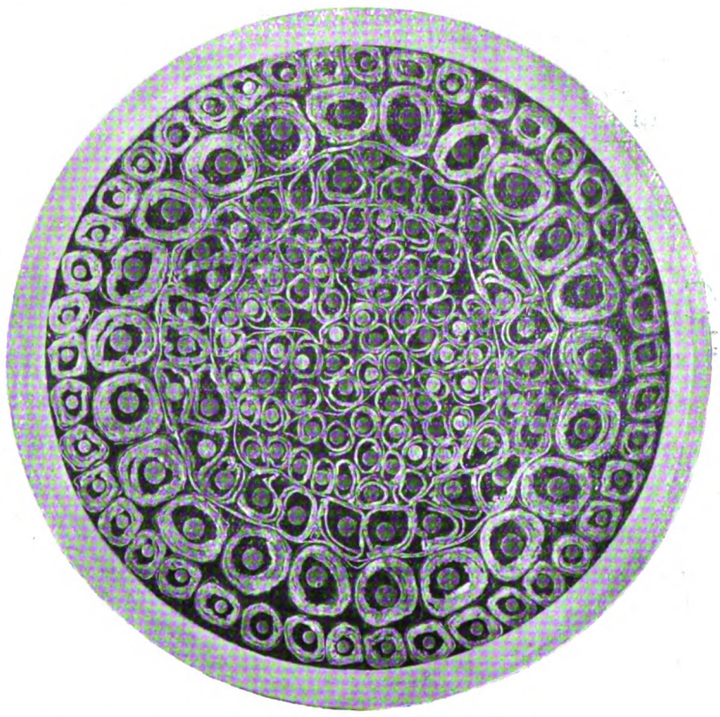

Fig. 2.—A Composite Telegraph and Telephone Cable used by the British Post Office. Full Size.

The telephone wires in the pairs and "quads" are insulated with manilla paper, applied longitudinally, and secured by a whipping of string. A similar longitudinal paper forms the first wrapping of the screened telegraph conductors, but in this case it is covered with three more paper wrappings laid spirally. The first two of the spiral wrappings are laid on so as to leave a helical air space, and the third forms a closed helix. Over this a wrapping of copper tape 3 mils. thick and $\frac{3}{8}$-in. wide, with a 30 per cent. overlap. The copper screening is, of course, to prevent inductive action between neighbouring wires.

The centre core consist of one "quad"—four pairs of 100-lb. conductors laid round a jute core. Surrounding this are six more quadruple pairs of the same size. The interstices left between these six quads are filled up by the six ordinary pairs of 100-lb. conductors as a "worming," making this layer circular. Over this

Digitized by Google

comes a layer of twenty-two 200-lb. single-screened conductors (each 350 mils. diameter overall), and the outside layer is made up of the forty-two 70-lb. single-screened conductors (each 225 mils. diameter overall). The screened conductors have a capacity of about 0·125 m.f. per mile; the capacities of the 70-lb. and 200-lb. conductors are practically the same, as the larger diameter of the latter is compensated by the greater distance between the wire and the screening. The 100-lb. telephone conductors have an average wire-to-wire capacity of 0·08 m.f. per mile, and the 150-lb. pairs 0·06 m.f. per mile.

It should be mentioned that the "wire-to-wire" capacities quoted in this article represent the capacity between the two wires of a pair, assuming both to be insulated. The capacity of each wire if its fellow is connected to the remaining wires and earthed, to form the second plate of the condenser, is, roughly, 40 per cent. higher.

As an additional precaution to prevent inductive effects between adjacent pairs of telephone wires, each of the four pairs of each quad are given a different "lay," varying from 7 in. to 12 in., and in laying up the pairs into the quadruple core a different lay varying fom 12 in. to 18 in. is taken in making each "quad." The lead sheathing is 160 mils. thick, and the outside diameter over lead $3\frac{3}{4}$ in., so that the cable can be drawn into a 4-in. pipe. The cable weighs about 34 tons per mile, and is made in lengths of about 150 yards.

SMALL TRANSFORMERS FOR METALLIC FILAMENT LAMPS

CONSUMERS of electrical energy for illuminating purposes are naturally anxious to avail themselves of the opportunity afforded, by the use of the new high-efficiency metallic filament lamps, of reducing their consumption. For the ordinary supply voltages of from 100 to 250 volts, small light units cannot be obtained, and it is necessary either to use a few large units, which gives a bad distribution of light, or in cases of alternating current circuits, to transform down from the supply voltage to 25 or 50 volts and run all lamps on this low-pressure circuit. A description of various types of transformers for this purpose was given in ELECTRICAL ENGINEERING, March 5th, page 351. The high initial cost of changing over a whole installation by making use of a central transformer and replacing all lamps may deter many consumers from considering the use of the new lamps at all, and in many cases it would be advisable to use metallic filament lamps in some places and the cheaper carbon filament lamps in others. Thus, in a basement room or a dark office where a lamp is burning all day long, the initial cost of a small transformer for the single lamp would soon be repaid by the saving in current consumption.

One of the latest types of small transformers for use with single lamps is that manufactured by the London Electric Transformer Co., of 10 City Road, E.C. This transformer is known as the "Adapter Transformer," and is of particularly light and compact construction. The standard type is illustrated in Fig. 2, in which the transformer is suspended from the flexible between the lamp and the switch. It can be placed in any other position, however, the chief advantage of the arrangement shown being that no alteration of the wiring of the room is needed. The transformer is placed in the lamp socket like any ordinary lamp, and the low-pressure lamp is placed in a socket provided at the lower end of the transformer. The diameter outside the cylindrical case is $1\frac{7}{8}$ in., and the total length, including a "turn down" switch, described later, is $5\frac{1}{2}$ in. The weight is about $1\frac{1}{2}$ lb. The small transformers described in the article already referred to were all auto-transformers, with a single winding. The "Adapter Transformer" is, however, a pure transformer with separate primary and secondary windings. An advantage of this arrangement is that the secondary winding is not at the same potential as the primary winding, as is the case in an auto-transformer. As the transformer is placed on the lamp side of the switch, the no-load losses need not be considered.

The construction of the transformer is shown in Fig. 1. A single core of high-grade iron strip is insulated, and first the primary and then the secondary winding is put on. The ends of the strips are then bent round at both ends and both sides to form a closed magnetic circuit. On account of the modern methods of insulation employed in the manufacture of the "Adapter Transformers," a very high space factor is attained. The finished transformer is enclosed in a bright polished brass sleeve, and spun brass caps are fitted to each end of the sleeve. The continuous capacity of the standard type illustrated in Fig. 2 is somewhat over 20 watts, and the usual arrangement is to use one of these in conjunction with one 16 c.p. 25 v. lamp, or two 10 c.p. 25 v. lamps. The transformers can be obtained for primary voltages of from 100 to 250 volts, and for

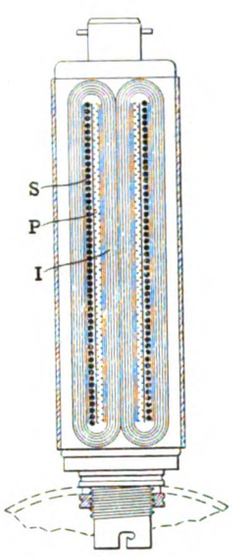

FIG. 1.—SECTION.

FIG. 2.—EXTERNAL VIEW.

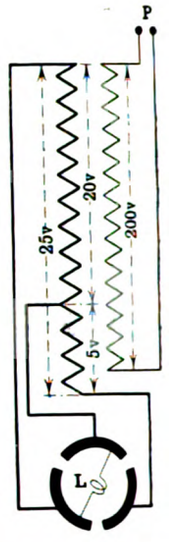

FIG. 3.—DIAGRAM OF CONNECTIONS.

ADAPTER TRANSFORMER WITH "TURN-DOWN" DEVICE.

a secondary voltage of 25 or 50 volts, and for any required frequency.

An ordinary carbon filament lamp consumes 3·75 watts per candle. Most metallic filament lamps consume about 1·2 watts per candle. The efficiency of the "Adapter Transformer" is 85 per cent., consequently the combined transformer and lamp will consume less than 1·5 watts per candle. Thus, in spite of the unavoidable loss in the iron and copper of the transformer (about 3·5 watts in all), a saving of over 60 per cent. is obtained.

At a slight extra cost a turn-down device can be fitted to the transformer; the lamp shown in Fig. 2 is provided with this,

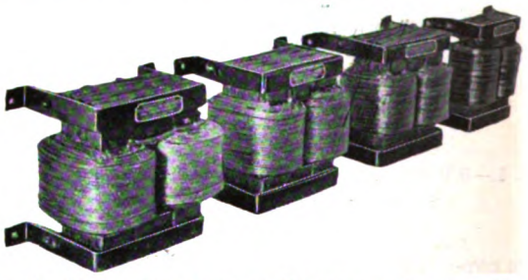

FIG. 4.—SMALL SINGLE-PHASE TRANSFORMERS FOR HOUSE LIGHTING.

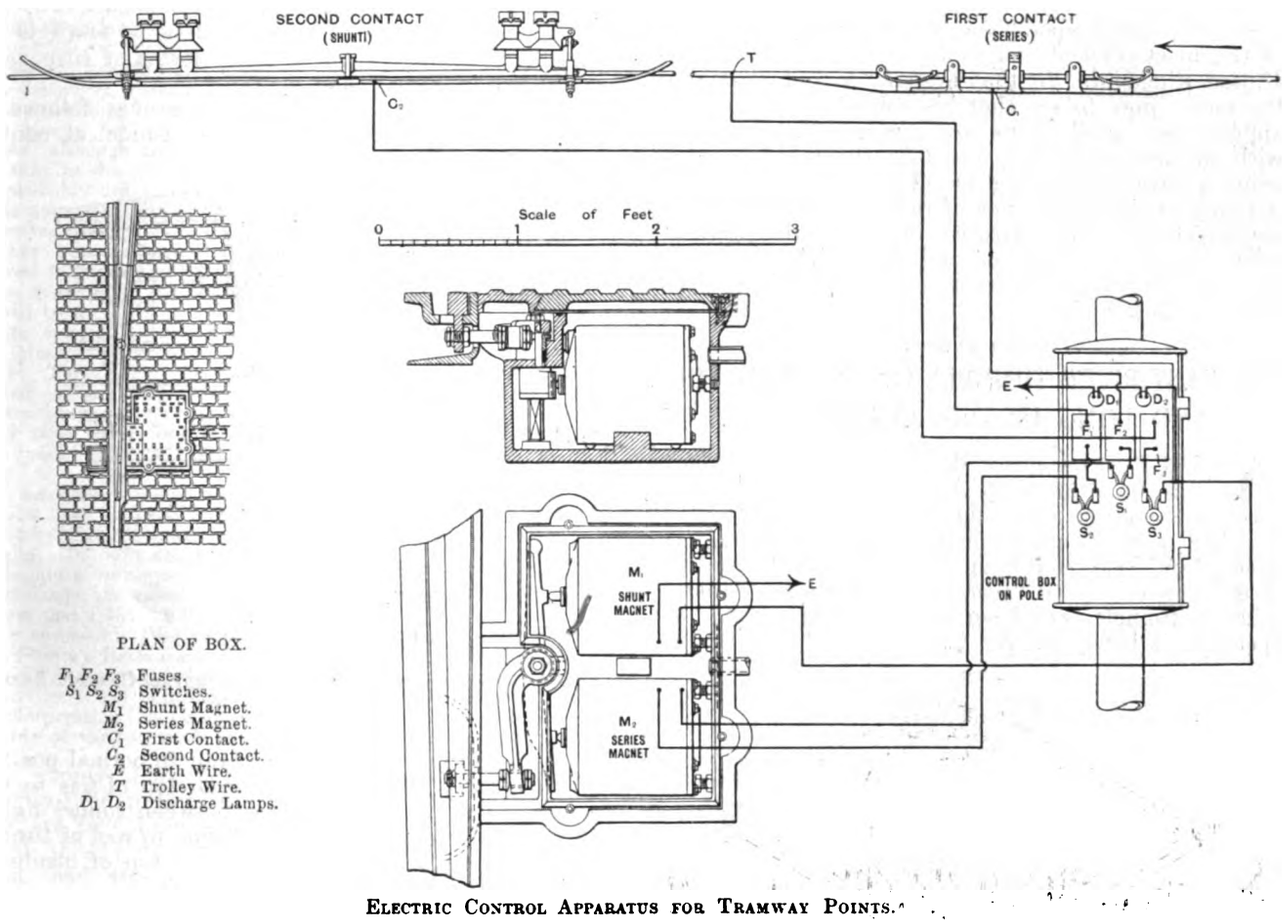
but it is not visible. By twisting the lamp socket, the lamp terminals are brought in contact with stationary contacts connected to different points on the secondary winding, as shown in Fig. 3. There are, as shown, three positions: (1) 25 volts (full voltage), corresponding to the full candle-power, say 16 c.p.; (2) 20 volts, corresponding to about 10 c.p.; and (3) 5 volts, which gives a mere glow suitable for a night-light in the nursery or sick room. In many cases, where the lamps are within reach, this means of varying the candle-power of the lamp will be found very convenient. For bedside or table use, the company supplies lamp stands in which the transformer forms the supporting pillar.

An interesting point in the design of the transformers is that, as the transformer is to work only at full load, the value of the no-load pressure is of no account, and any drop can be allowed, so long as the full-load terminal voltage is the proper voltage for the lamp to be used. This permits of a much more economical design, as the only factor to be considered is the heating of the iron and copper and the losses. The latter must, of course, be kept low in order that the watts per candle may,

Digitized by Google



in spite of these losses, be still very much less than the value of 3·75, as obtained with a carbon lamp. As before stated, the losses total to less than 4 watts on full load.

The company also manufacture a line of single-phase transformers for dealing with part or whole of a house system. Four of these are illustrated in Fig. 4. The outputs range from 80 to 5,000 watts; the 80 watt size has a full load efficiency of 88 per cent., and a half-load efficiency of 89 per cent. The larger sizes have, of course, higher efficiencies. These transformers are designed for low no-load losses, as they are supposed to be always in circuit. Thus the iron loss for the 80 watt size is only 3 watts, for the 1,000 watt size 14 watts, and so on. The 160 watt size, which would deal with an installation of 10 16-c.p. lamps, measures only 6 in. by 5 in. by 2½ in. In cases where it has been decided to replace all the carbon filament lamps by metallic filament lamps, it would, of course, be more economical to install a single transformer than to provide each lamp with a separate transformer, and in general it is found that the house wiring is of sufficient size to withstand the slightly increased current density.

THE CONTROL OF TRAMWAY POINTS BY ELECTRICITY

THE development of tramway systems involves in the majority of large towns a considerable amount of branching out from one route into another, and where the service is heavy or rapid the usual method of allowing the driver of the car to carry a rod or lever with which to work the points is hardly practicable from the point of view of loss of time in the operation. When, therefore, the service of cars becomes rapid past any particular point, it has been the custom in the past to station a boy, whose function is to watch for the approach of any car, to determine along which route it must travel, and to arrange the points accordingly in advance of the car. The cost of this arrangement is somewhat in excess of its practical utility where the system is at all complex. The wages of such a lad may range from 8s. to 12s. a week, and a change of individuals is necessary for at least two eight-hour shifts out of the three. In addition to this a uniform has generally to be provided, so that switching arrangements by manual labour on an ordinary tramway system is an expense which may conveniently be cut down.

There has recently been introduced an electrical system of point control operation, the patent of Messrs. Tierney & Malone, and we are indebted for particulars of this apparatus to Messrs. Brecknell, Munro & Rogers, Ltd., of London, E.C., who are the manufacturers of the gear. The illustration shows diagrammatically the arrangement of the control, the direction of the car being indicated by the arrow pointing right to left. The switching lever, which is contained in a street box adjacent to the point, is operated by means of series and shunt magnets, M_2 and M_1 respectively. The series magnet is connected through switch S_1 and S_2 to the trolley wire T, and an insulated strip C_1 respectively. On the arrival of the trolley wire at the strip C_1 current passes from the live wire through switch S_1 to the series magnet back through S_2 to the insulated strip, and thence through the car controller and motors to rail, provided that the controller is at the time in an "on" position. Should, however, the controller be switched off at the moment, no current will pass. The operation of the series magnet is to pull the point over towards the box, allowing the tram to proceed in a certain direction at the junction. Immediately the trolley has passed forward to the second contact past C_1 the shunt magnet comes into operation by means of current passing from C_2 through switch S_3 to the shunt

ELECTRIC CONTROL APPARATUS FOR TRAMWAY POINTS.

Digitized by Google

magnet M_1, and so to earth. Should the point have been displaced by the action of the series magnet it will, on the arrival of the trolley, which makes contact between point C_1 and the main trolley wire in passing, switch the point back to its first position.

We have then a device which puts the point in one or other position, according as to whether the motor man has his controller in an on or off position at the moment of passing the first contact. In this way the driver can himself determine in which direction he is going to travel, without appreciably checking the speed of the car. The control box, which is located on the nearest tramway pole, contains, in addition to the switches and fuses, a lamp resistance which forms the discharge to earth for protecting the shunt coil. It will be seen that the return of the tongue is automatically performed by the passage of the car, and is quite independent of any act of the motorman. The price of each of these equipments would be about £70, exclusive of erection and connection, and this small capital charge would speedily be repaid by the saving of time effected in the service, and the abolition of the manual operation with its attendant revenue charges. This system of electric point control is in active operation in Newcastle-upon-Tyne, which town possesses one of the most efficient and rapid services of cars in the United Kingdom. In that system, in order to allow the motor man to see that his point is in order as he approaches, signal lamps are arranged in connection with the control box, operated by the position of the point, a green lamp being placed at the centre and two red ones at either side, one of these being lit, the other extinguished in either position of the tongue. By the relative position of the red and green light, therefore, the motor man can determine how his points stand, even on dark nights.

THE EAST RIVER TUNNELS OF THE NEW YORK AND LONG ISLAND RAILROAD CO.

A PAPER was read by Mr. L. B. Stillwell recently before the New York Railroad Club, in which an account was given of the electrical features of the New York and Long Island Railroad Company's tunnels between New York and Long Island City. An abstract of the Paper is given in the *Street Railway Journal*.

These tunnels have been ready for some time, but operation is being deferred until certain franchise diffi-

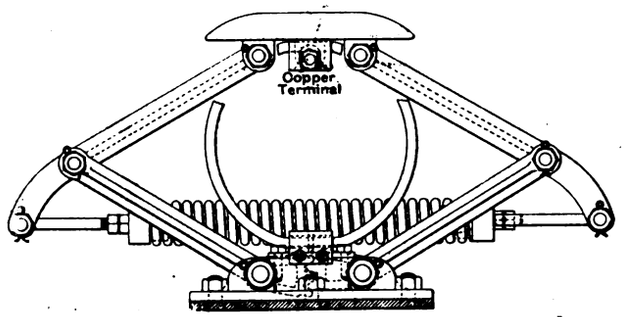


Fig. 1.—Current Collector for Cars running in East River Tunnels, New York.

culties are adjusted with New York City. The cars are of steel construction but of surface type, as many of them will continue as through cars over different routes of the allied New York and Queens County Railroad Company.

When operated over the 600-volt city lines these cars will collect current through the company's standard trolley wheel and pole. The restricted space in the tunnel section made it necessary to add to the cars a more compact and reliable form of current collector. This collector is shown in Fig. 1, and consists of a pantograph similar to that applied on the New York Central electric locomotives, but of smaller dimensions. In its lowest position this contact shoe is only 8 in. above the roof of the car, 11⅜ in. in its normal running position and 1 ft. 4 in. in its highest position.

Current is taken from a contact rail placed in line

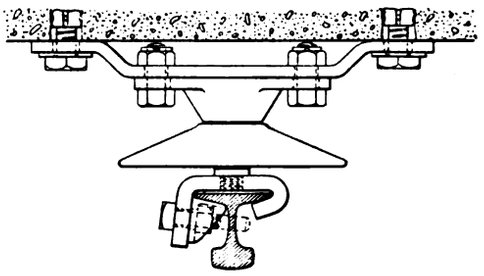

Fig. 2.—Arrangement of Overhead Contact Rail in Concrete Section.

with the centre of the tunnel. This rail is of standard T section weighing 20 lb. per yard, and supported at intervals of 9 ft. The rail is carried head down, and is secured to the insulator and bolted to brackets adjustable in four directions. Two forms of suspension are shown in Figs. 2 and 3.

The principal tunnel dimensions are as follows:—Height from top of ties to roof of tunnel at centre,

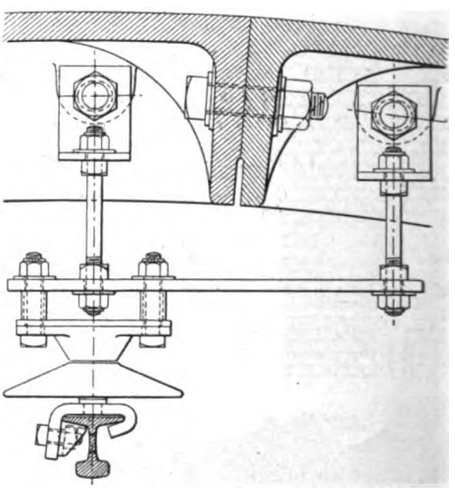

Fig. 3.—Adjustable Bracket for Overhead Contact Rail in Cast-iron Section.

14 ft. 2 in.; height from top of rail to normal position of shoe, 12 ft. 4⅝ in.; height from top of ties to roof of car, 11 ft. 11 in.; distance between tunnel lights, 10 ft. 8 in.; height from top of shoe to roof of tunnel, 15⅝ in.; height from top of shoe to top of insulator, 6½ in.

Royal Institution.—The annual meeting of the members of the Royal Institution was held last Friday, Sir James Crichton-Browne, treasurer and vice-president, in the chair. The annual report was read, and the following gentlemen were unanimously elected as officers for the ensuing year:—President, the Duke of Northumberland; Treasurer, Sir James Crichton-Browne; Secretary, Sir William Crookes; Managers, Sir Thomas Barlow, Bart., Sir George Darwin, the Rt. Hon. the Earl of Halsbury, W. A. B. Burdett-Coutts, Esq., Charles Hawskley, Esq., Dr. Donald William Charles Hood, Dr. Rudolph Messel, Henry Francis Makins, Esq., George Matthey, Esq., Dr. Ludwig Mond, the Rt. Hon. Sir John Fletcher Moulton, Alexander Siemens, Esq., the Rt. Hon. Sir James Stirling, the Rt. Hon. the Earl of Rosse, and Sir William H. White; Visitors, Arthur N. Butt, Esq., Dugald Clerk, Esq., Charles A. Ballance, Esq., John B. Broun-Morison, Esq., Edward Dent, Esq., John Cameron Graham, Esq., Dr. James Dundas Grant, Charles Edward Groves, Esq., Sir Henry Harben, Major E. H. Hills, John List, Esq., Robert Mond, Esq., Francis Lys Smith, Esq., James Swinburne, Esq., and Lieut.-Colonel Sir Frederick Nathan.

NOTES ON THE LIGHTING OF THE SCOTTISH NATIONAL EXHIBITION

THIS exhibition was opened at Edinburgh on Friday by H.R.H. Prince Arthur of Connaught, and although there is a considerable amount of electric lighting, we cannot but think that the most interesting feature of the exhibition to electrical engineers will be the large employment of gas lighting in the grounds. Electrical engineers should keep themselves fully acquainted with what their competitors are doing, and we therefore need make no apology for giving an account of the gas lighting arrangements before dealing with the electrical distribution.

The site of the Exhibition is the Saughton Hall estate, which is situated at the old cable-car terminus at Gorgie. The main entrance is here, and is lighted with "Vesta Graetzin" inverted self-intensifying gas lamps, each of 400 c.p. The main avenue from this entrance is lighted with Messrs. Keith & Blackman's high-pressure gas lamps, each stated to be of 1,500 c.p. These lamps are carried on standards of graceful design, and are about 15 yards apart, alternately on either side of the avenue. The central square, around which the main buildings are grouped, is also lighted with similar lamps, each standard carrying three lamps here. The cluster of three lamps is stated to give 4,500 c.p. There are 127 of these lamps altogether.

Immediately inside the main entrance is the gas-compressor plant, driven by a small gas engine; this raises the pressure up to from 54 to 62 in. maximum, and is in duplicate. The lamps give a brilliant, hard white light, with an absence of shadows, although the enclosing globes are of clear glass. The effect may be described as more decorative than "illuminative." It is probably unfair to criticise these lamps so early, but some trouble appeared to be experienced on the first two nights, probably owing to mantles breaking; we are informed that 62 in. is a higher pressure than has before been attempted. It also appeared to us that the lamps gave by no means equal candle-powers, some being much more brilliant than others. Doubtless this will be rectified.

There are 36 low-pressure gas lamps in the gardens, these being Messrs. Anderson & Co.'s "Pharos" lamps, giving each 650 c.p. These, being intended to light narrow walks only, are mounted on low posts, hence their illuminating effect compared with arc lamps cannot very well be judged. The bandstand is lighted from the ceiling with 12 "Nero Graetzin" gas lamps, giving each 220 c.p. They are enclosed in obscured glass globes.

The art gallery is lighted with Messrs. J. & W. B. Smith's "Empire" gas lamps of 350 c.p. each. We understand that gas was preferred here to electric light on account of the colour of the light. To light art galleries by gas instead of electric light is certainly a retrograde step, and with the present choice of electric lamps the colour difficulty is certainly non-existent. It is stated that 1,400 candle-power is obtained for one pennyworth of gas consumed! (We suppose 1,400 c.p.-hours are meant.)

The Prince's Restaurant is also lighted with incandescent gas. For the lighting of this building and others, competitive tenders were invited; this building was secured by the Edinburgh and Leith Corporation Gas Commissioners. There are some 700 other gas-lights of various kinds in different buildings.

The supply of electric light and power is obtained from the Edinburgh Corporation, Dewar Place station. There are two main supplies, one low-tension direct-current three-wire supply, with 460 volts across the outers, and the other an alternating high-tension supply at 2,000 volts, feeding static transformers, part of which give a supply at 230 volts and part at 115 volts.

The low-tension supply is run direct from the station, and is carried into a main distributing room in the Industrial Hall. The three cables are here carried round the walls of the room, and tappings are taken off through fuses and meters to the distributors. The feeder cables are lead covered, paper insulated and braided. Where they pass through the exhibition grounds they are drawn into cheap earthenware ducts, which may be abandoned when the cables are withdrawn; a pilot cable has also been run. The capacity of these cables is about 300 kw.

From this central distributing point three-wire circuits have been carried to the various buildings. This part of the work has been carried out by the British Insulated & Helsby Cable Co. Each circuit consists of a two-pole concentric cable and a single cable, the latter being the neutral wire. The cables are plain lead-covered and paper insulated, and are buried in impregnated wooden troughing with a wood cover, but no filling is used. These cables will all be dug up again on the close of the exhibition.

The cables finish in their respective buildings in sealing and dividing boxes, and tailings are taken from these boxes to distributing boards. From the boards two-wire circuits are run at 230 volts for incandescent lighting and small motors, these circuits being balanced against each other. For arc light circuits and larger motors 460-volt mains are run. The wiring consists of rubber cables, mounted on porcelain insulators; the greater part has been done by Messrs. Lowdon Bros., Edinburgh. Each stall is supplied through a Ferranti meter. The high-tension supply is conveyed by two concentric cables, each of 0·1 sq. in. section, run in parallel. These cables are brought in by a different route to the low-tension cables, and, like the L.T. feeders, are mainly drawn into existing ducts belonging to the Corporation; when they enter the exhibition grounds they are pulled into earthenware pipes. A brick building with a galvanised iron roof has been erected for a sub-station. The transformers are arranged in five distinct groups to feed five different circuits, three of which will be at 115 volts pressure and two at 230 volts. Five concentric distributors have been brought to this point by the B.I. & H. Co., laid in wood troughing underground. Both secondary conductors are insulated from earth. The lead of these cables is earthed to a water-pipe, both at the transformer house and at the distributing points. The high-tension cables are run down the centre of the room and a connection is taken through an oil switch and fuse to each transformer. The secondaries of the transformers are led through a switch and fuses to one of five pairs of insulated 'bus bars. A connection is made from each 'bus bar through a meter to the distributor. Any transformer may thus be isolated both on the primary and secondary sides. The total capacity is about 275 kw.

The alternating supply will be chiefly used for outside decorative incandescent lighting, and will probably be entirely switched off during the day-time. There will be some 8,000 lights used for this purpose, but this work has not yet been done, as, owing to the long evenings of the early summer in Scotland, the effect of the illuminations would be largely wasted until August, since the exhibition closes at 10 p.m. each night.

The direct-current lighting is by means of 250 arc lamps and some 5,000 incandescent lamps. The incandescent lamps installed by the exhibition authorities are all of carbon filaments, but many of the stalls are lighted by various kinds of metallic filament lamps. The arc lamps are Messrs. Crompton's "Crompton-Blondel" flame type and Davy's "Sunræ" flame lamp. The "Crompton-Blondel" lamps are run eight in series off 460 volts, and take 7 amps.; they use 15″ single carbons. The Concert Hall is very effectively lit with eight of these lamps suspended from the ceiling. They give a very pleasing white light, which seems to give true colour values. These lamps are also used for lighting the Industrial Hall. The Davy lamps are used in the Machinery Hall, the Winter Gardens, and for outside lighting; they are also very effective. They are connected eight in series and take 10 amperes.

Owing to the recent heavy snow, the outside arc-

lighting was not completed on the occasion of our visit. It is mainly confined to the outer walks. The whole of the lighting arrangements, together with all the other engineering work in connection with the exhibition, has been carried out under the supervision of Mr. A. C. Freeman, engineer to the exhibition authorities, to whom we are indebted for most of the above particulars.

NEW ALTERNATING CURRENT INSTRUMENTS

Birmingham Discussion

THE Paper on the above subject by Dr. W. E. Sumpner and Mr. J. W. Record, which was read and discussed at the London meeting of the Institution of Electrical Engineers in London on March 19th, was further discussed in Birmingham on April 8th. The Paper itself was given at some length, together with a report of the discussion in London, in ELECTRICAL ENGINEERING, March 26th, page 481.
